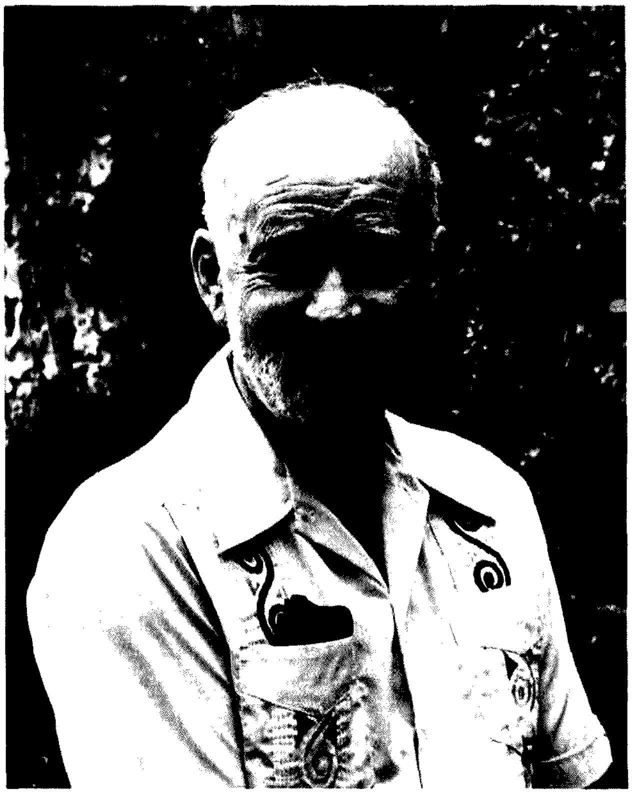
NEVER SAY DIE
editorial by Wayne Green

SAM HARRIS W1FZJ

On page 8 of the September issue of *73*, we printed a picture of Sam Harris and his wife Helen. Word arrived from his son, Pat, that Sam died in early November. VHFers will miss him.

For some reason, Sam and I clicked early on . . . I think it was around 1948 or so that we began to get into extended contacts on the low end of 75m. We both shared an interest in 75m DXing . . . in VHF . . . and in learning more about the anomalies of life. When I moved out to Cleveland and became W8NSD in 1951, I visited Sam and Helen at their farm just east of Cleveland. Sam was W8UKS at that time. We talked just about every evening on 75m.

Later, when I became the editor of *CQ* in 1955, Sam signed on as VHF editor and did a splendid job. During those days, I occasionally had a chance to drive or fly (I had a plane then) up to visit him in Medfield, just outside of Boston, and sack out on his living room couch.



Sam Harris W1FZJ.

Sam was one of those who said what he thought of people, pulling few punches. I remember a luncheon with the president of National Radio, where this chap asked Sam what he thought of their new receiver. Sam told him in no uncertain terms what he thought of their overpriced, unstable, easily overloaded bomb.

We get so used to kids wearing beards these days that we tend to forget that it wasn't long ago when a man with a beard was an unusual sight. Sam always had a beard . . . might have been born with one, for all I know. I asked him if the stares on the street ever bothered him, and he said they did sometimes . . . made him wonder if his fly was open.

Sam was not a difficult man to deal with or understand once you grasped that amateur radio came first, second, and perhaps even third in his life. Helen got used to it early on, and brought him his meals and coffee at his operating desk. This preoccupation with hamming manifested itself in a way that was helpful to many of us: He *had* to have the loudest signal in the world on a band before he would get active on it.

The antennas and towers which this conviction brought about have appeared in many magazine articles. I once ran an article by Sam on his "contest 100-Watt amplifier." I still pull out that article when I want to collapse a visiting ham with laughter. The final actually ran about 7,000 Watts, and consisted of separate finals for each of the low bands (which were built into Sam's garage). The article was a spoof of the 100-Watt listings in *QST* contest results, where many hams

CONTESTS

HUNTING LIONS ON THE AIR CONTEST

Starts: 1200 GMT, January 13
Ends: 1200 GMT, January 14

The contest is sponsored by Lions International and coordinated by the Lions Club of Rio de Janeiro (Arpoador), Brazil. Participation is open to all licensed radio operators except members of the contest committee. The contest will be separated into two sections, phone and CW, with points counting separately and participation allowed in both modes. All bands 80 through 10 meters may be used, with each station being contacted no more than once per band and mode. When contacts are made between Lions and Leos, the name of the Lions Club or Leo Club contacted should be noted in the log. Confirmation of contacts will be made by log comparisons.

SCORING:

QSOs within the same continent count 1 point each; between different continents, 3 points. Bonus points: 1 extra point for a QSO with member of a Lions or Leo Club and 5 extra points for a QSO with a member of the Rio de Janeiro (Arpoador) Lions Club. Contacts between members of the Arpoador Club will not count any bonus points.

ENTRIES AND AWARDS:

Lions International will present first-, second-, and third-place awards in two categories—phone and CW. The first place winner in each category will receive a trophy, the second a medallion, and the third a plaque. The Lions Club of Rio de Janeiro will award additional vermillion award medallions to the fourth- through tenth-place winners. Each participant making more than 20 points will receive a special QSL from the Lions Club of Rio de Janeiro. Logs for each mode showing time and callsign should be sent to the contest committee no later than 30 days after the contest: Lions Club of Rio de Janeiro (Arpoador), Rua Souza Lima n. 310—Apt. 802, Rio de Janeiro 22.081, ZC-37 Brazil.

IAAH AIRLINE CONTEST

Starts: 1500 GMT Saturday, January 27
Ends: 1500 GMT Sunday, January 28

Sponsored by the International Association of Airline Hams (IAAH), this is their first annual contest open to all "airline hams" and non-members. Members of the IAAH may work both members and non-members, and vice versa. Certificates will be given to the top 3 scorers in each of the two categories (members and non-members). Multi-op counts as one station. General call is "CQ Air Contest," etc.

EXCHANGE:

Non-members, five: "non-member," consecutive serial number, signal report, state, province, or country.

Members, five (the same as for non-members), except: "member," IAAH roster number, 3-letter airport identifier (if applicable), flight number or aircraft number if station is "aeronautical mobile."

Please Note: Specific laws apply to hams operating their equipment from on board an aircraft. Please contact the IAAH for rules BEFORE doing this!

SCORING:

Score 4 points for "airport operations" such as W9XYZ/9 at O'Hare Airport; score 5 points for contact with an "aeronautical mobile"; all others score 1 point each. Then add the total number of points, including bonus points. Add the total number of multipliers (states, countries, and Canadian provinces) and multiply the total points by the total multiplier for the final score.

ENTRIES:

Submit all logs, separate logs for each band, to: Frank Sadilek WB9OUE, 3818 N. Newcastle Avenue, Chicago IL 60634. Deadline for submitted logs will be March 1.

SUGGESTED FREQUENCIES:

CW—3550, 7050, 14050, 21050, 28050, 50095.

SSB—3975, 7275, 14280, 21375, 28550, 50105.

Novice/Tech—3725, 7125, 21125, 28125.

FM—146.52 and/or 146.55 simplex; duplex through a repeater is permissible!

WORKED COLUMBIA AND GREENE COUNTIES AWARD

Offered by the Rip Van Winkle Amateur Radio Society of Columbia and Greene Counties, New York, the award is given for having two-way contacts by amateur radio with two stations in each of Columbia and Greene Counties, New York. Contacts may be on any band or mode, except that repeaters may not be used. Send log information and $1.00 to: Rip Van Winkle ARS, PO Box 1028, Hudson NY 12534.

FRENCH CONTEST

CW
Starts: 0000 GMT, January 27
Ends: 2400 GMT, January 28
Phone
Starts: 0000 GMT, February 24
Ends: 2400 GMT, February 25

All contacts must be made on 160 meter CW (or 1,826 MHz for F stations). All entries must be single operator.

EXCHANGE:

RS(T) and QSO number.

SCORING:

Score 3 points for each F or overseas French department or territory contacted in your own continent (10 points if in another continent). Multipliers are each F department (95) and DA1/2 STN/FFA (F forces in DL),

LETTERS

DRAWBACK?

Your latest issue is the best yet, and one of the fattest I've ever seen. You're approaching Japanese *CQ ham radio* girth. The only drawback was your taking on the Chrysler Corp. I don't think ham radio needs any more powerful opponents and I for one wish you'd keep your printed opinions in the ham radio arena. There are certainly enough electronic foibles to aim your barbs at, aren't there? If you're running short, let me suggest DX list operations, blatant business phone patches, the FCC considering overseas religious missions to be business, and the FCC's inability to run a computer rather than be run by it.

David L. Bell W6AQ
Hollywood CA

PERISH THE THOUGHT!

After reading your editorial in the September issue of *73*, I just had to let you know how strongly I agree with what you say about the ITU and WARC and the effect the deliberations of WARC may have on the future of amateur radio as we know it today.

The reason I can so readily agree with you is that I am familiar with the operations of the ITU and its associate agencies. My first participation was while I was a member of a Canadian R & D organization then up to my retirement in 1973 as a consultant with the Canadian Department of Communications (DOC). I think that many amateurs are not fully aware of what the ITU really is and what it does. The ITU, a specialized agency of the United Nations, has, among other activities, two very important consultative committees. One of these is the CCITT, the International Consultative Committee for Telephones and Telegraph. The other is the CCIR, the International Consultative Committee for Radio. It is my feeling that it was in the CCIR that we amateurs should have had most interest and this should have extended back for many years. As you indicated in your editorial, this committee deals in all areas of radio telecommunications. These areas are divided into about a dozen study groups, such as for marine radio, radio astronomy, television, radio satellites, and, of course, radio telecommunications in all frequencies from the lowest to the GHz and up. It is also probably not known to many amateurs that the only recognized participants in these study groups are the official government representatives of the member United Nations countries. Each of these administrations may include in their delegation certain specialists by personally inviting them and also informing Geneva. It is easy to understand that in the aggregate these specialists probably include the world's most knowledgeable people in all areas of telecommunications. Unfortunately, only a very few of these are amateurs, although none was selected for this reason. There is no study group dealing in amateur radio.

In addition to the international study group meetings, most administrations held national meetings paralleling these SGs. These national meetings would be held in the interval between the international meetings to prepare the administrations for the next Geneva meeting. The discussions in the national meetings were highly technical. The participants came from all national fields and represented many manufacturers, telecommunication companies, the television industry, many users such as public utilities, police, and others. Only a few of these people would be part of the international delegation.

Unfortunately, so far as I was aware, there was little or no participation in these national meetings although the DOC had indicated that such participation was acceptable.

Participation for WARC does include a number of national meetings, but we must be aware that these are not technical meetings. The technical meetings of the CCIR provided the CCIR recommendations as contained in the Green books, which would of course lend weight to the WARC in its decisions. It can be seen that the work of WARC will not be supported by the many specialists that we saw in the CCIR, but rather by a relatively few people that are directly concerned with the national policy. It is quite possible that many delegations will have no amateurs, and this a definite certainty in the delegates in those countries that do not now have any amateurs. It is also the case that some administrations that do permit amateur activity in their countries are somewhat indifferent as to amateur survival.

What I may not have brought out here is a fact that some amateurs are not fully aware of, and that is that all of the meetings of the ITU and its associated agencies are closed meetings. There is one and only one voice at these meetings, and that is of the official administrative voice of the United Nations current member countries.

It is difficult for me to understand how an almost "no face," an organization that has not actively participated in and identified itself in the technical area (the CCIR), can hope to justify its existence at a WARC meeting where it has no voice and where a number, too many, of the administrations either do not have or do not want amateurs. Not only that, but many administrations that are otherwise in favor of amateurs would have no scruples in subordinating this if it interfered with other national more pressing needs.

Probably I agree so fully with you because, like you, I have attended these meetings and thus could sense the direction in which they seemed to lead. I hope that we are both mistaken and that we will be able to enjoy amateur radio as we now know it for many more years. I would hate to have to go underground. Perish the thought!

As insurance against total insanity if we do lose out, I have infected myself with a counterinsanity. I am becoming active in the microcomputer field, having obtained a TRS-80. With the help of *Kilobaud*, I trust this new insanity will make me impervious to any bad news from WARC.

My best 73s and may your cassettes never become demagnetized so you will always be able to CLOAD!

H.F. Hannay VE7WO
Nanaimo BC
Canada

BLESSING IN DISGUISE

It looks like your brain is finally starting to soften up, Wayne. "Never Say Die" in the October, 1978, issue sounded like you've been experimenting with drugs more than radio. Docket 20777 would have been the best thing for amateur radio since **SSB**. Not perfect, maybe, but a lot better than what we have now. CW is okay, but to devote over half our HF spectrum to it is nonsense. Why doesn't someone look at amateur radio as it really is, not as it once was or as they wish it would be.

If amateur radio is gutted by the ITU next year, it will be a blessing in disguise. The deregulation you (and I) want will be an overnight fact. Once the challenge of "illegal" operation is overcome, things like bandwidth, subbands, bandedge, mode, power, and class of license all fade into insignificance. It will be almost as much fun as Peterborough to New York in 2½ hours! QRP, indoor antennas, and inexpensive fun operating CW would be reborn, TVI and tower problems would be eliminated, and licensing hassles would be forgotten.

Banning amateur radio would be the best thing that ever happened to it. No one outside amateur radio cares about it one way or the other. The only outside interest we get is bad (towers and TVI). If we went underground, the towers and TVI would disappear. We would have more operating freedom than we've ever had. As long as our operations did not interfere with "outsiders" and thus generate complaints, the FCC would remain sound asleep, as they have been for decades. What happens if they wake up, you ask? That would take millions of dollars, money they don't have and aren't likely to get.

Besides that, amateur radio is big business, and if for no other reason, we won't lose a single kHz of HF spectrum at the ITU meeting. We might even gain a little. Satellite communication, and the VHF/UHF frequencies required for it, is where we are going to lose our shorts.

Robert Seeber
Littleton CO

P.S. One of these days you are going to wish you had your 240Z back. However, I wouldn't trade my 1974 B200 Dodge van for anything.

STIRRED BLOOD

Congratulations on your finest editorial yet, Wayne, in the October issue of *73*.

Please bear with me, and I'll give you one more example of the stupidity of some of their hard and fast rules at the FCC.

In August, 1921, I took a written test and written code test from a Mr. Paul Ord, then assis-

tant radio inspector out of San Francisco. It was in Stockton CA, and I was a 12-year-old kid running errands for the men who built and operated KWG, and they believed it was to be the first commercial broadcasting station. I operated my own 1 kW rotary spark-gap transmitter and homemade receiver. My best DX was from near Stockton CA, to Bozeman MT. I had many friends ten years or so my senior, and they were always ready to answer my many questions.

My principal at the high school expelled me in my junior year because I was a bad boy for not studying my history, English, etc., and I was the least likely boy to succeed in this world!

I went to San Diego and joined the Navy. I taught radio classes and theory at the school for about one year and then went aboard the *USS Idaho* for the rest of my enlistment of four years. Aboard the *Idaho* less than one hour, the communications officer, Ensign Charles F. Horn, called me to his office. Could I make a new crystal-controlled oscillator, a 211 50-Watt tube followed by another 211 amplifier, work? Earlier, one of my seniors had explained how to "neutralize" an amplifier to prevent self-oscillation. It worked! The *USS Idaho* had the first rig that would work. The Bureau of Ships diagram had not included a system to neutralize the final! Ensign Charles Horn received all the credit, but he put me in charge of all radio maintenance, and I bought a folding cot and lived in the material repair shop.

From the US Navy, I went to work at KFSD broadcast station in San Diego, and my lifetime was devoted to the broadcast business—KFI, KTTV, KEYT-TV, KTTV, etc.

In 1925, I took my Commercial First Class test in San Francisco and was given a test covering arc and spark. No problem. So I still have my Commercial First Class Telegraph and Telephone licenses.

In 1934, I experimented with a copper toilet bowl float and stumbled upon what may have been the first cavity system. Professors at Cal Tech, Pasadena CA, at least thought so. I built one for a young student which was at about 300 MHz, with the antenna at the focal point of a 4-foot parabola which was made in the Cal Tech shops. A small "perch" was attached to the parabola at the focal point about one foot beyond the radiator and was used to study the effects of rf upon insects. As a result, the student obtained his master's degree.

Then came WWII and I was the first person to be interviewed on the west coast by Dr. Louis Redenour (a close friend of the young student at Cal Tech), who was recruiting research people to go to MIT and design radar systems. I professed to know nothing about radar. I was politely informed that he knew all about my past history, and that I was to prepare to leave for MIT the following day, *or else!*

At MIT, I soon learned that the country's leading physicists were really smart, but most did not know how to work with their hands.

I developed gun-pointing systems. They included the system for the black widow night fighter. Upon intercept of a "bogey," the pilot would throw the switch to automatic, sit back, and relax while the plane flew via radar-controlled autopilot to an intercept at about 1200 yards. The guns would automatically fire and the plane would start to follow the enemy toward the earth, at which point the pilot would throw the switch back to manual and fly away. I also developed the AN/APG-15 gun-pointing system for the tail gunner in B-29s. I outfitted five B-29s at Bedford Airport and took them to India with full crews and turned them over to Gen. Curtis Lemay. The first, second, and third nights out over Japan, one Jap fighter was shot down each night. The fourth day, they switched to kamikaze head-on attacks. (In the meantime, a contract had been let to built 10,000 AN-APG-15 systems! But we did not need them then!)

After the war, I went back into broadcasting. I designed and built the triband gamma match feed system for beams. Mr. Andy Andros called long distance after reading a small report in *QST* and wanted to know what I was going to do with the idea. I said "nothing" and that if he was interested, I would give him a written release. I did, and hence the "Hy-Gain Corp." Andy retired with ulcers; I'm fat and sassy.

I developed many other items such as antenna-measuring devices, a "better" noise bridge generator (*73*), etc.

So, to the point of my writing. About four years ago, after working full time to make a living, I decided to go to San Francisco and get my Extra Class license. I failed! I found that the years had caught up with me; I could not remember rules or sufficient math to answer the damned tricky Philly-lawyer's questions. My wife gently informed me she was well aware that my mind was not what it used to be! I walked out of the examiner's office in San Francisco in tears. I went to the parking lot and sat in the car for an hour before starting home. What a *terrible shock!*

At a Las Vegas convention about three years ago, I spoke to Johnny Johnson about my plight. No sympathy. I informed him that I was damned fed up with such bureaucracy, and that I would henceforth operate in any portion of the ham bands I chose, and that I would see the FCC in a Federal Court if any action was taken against me. And I have operated to some extent when I hear a long-lost friend.

I'm an old devotee of Col. Claire Foster 6HM, and I have hated the ARRL gang ever since. Yes, I subscribed to *QST* for one year, and that will expire within a month or so. No more!

Soooo, your editorial in *73*, October, 1978, stirred my blood, and I hope you can do some good. I've taken *73* steady since you first started.

My best wishes to you, and continued strength to fight.

Lloyd M. Jones W6DOB
Salinas CA

Thanks for taking the time to write, Lloyd. I enjoyed your letter.

Frankly, I don't blame Johnny for ignoring you. You can't fool me. That soft-in-the-head bit doesn't wash. You have no problem with remembering anything; you just don't want to bother boning up for that damned Extra Class exam. I don't blame you on that one. It will be a well-frozen-over hell before they get me down for that one.

But the fact remains that if you want to pass the Extra exam, you can. I'm willing to bet that you didn't do your homework on this one. Did you get my Extra Class book and read it? Of course you didn't.

It's a pity that someone doesn't do some research and do a good article on Col. Foster. Newer hams should know about him and his battles with the League. As I recall, he didn't really get mad at 'em until after Maxim had kicked the bucket. I suspect they were a lot better under Maxim. I've enjoyed all of the Maxim books and suspect that he and I would have been friends if I had come along 20 years sooner . . . or if he had lasted longer. I've also read a lot of Foster's editorials and they were right on the mark.

Keep it flying, Lloyd.—Wayne.

WHAT SAY, NSD?

I enjoy most of your editorial comments, in particular those regarding the ARRL. The remarks are, for the most part, exactly my sentiments, even though I am a life member of the League.

It seems to me, though, that you are overlooking one of the most important parts of the best argument for having such an organization. That is the fact that, even though many of us do not like it, they, through a very powerful membership, do represent amateur radio in making the laws and regulatory features of our licensing bureau, the FCC.

If a move were to increase the membership of this so-called organization to a greater level, including all of the amateurs who feel that the League is an outmoded, poorly operated, antiquated-in-thinking organization, perhaps a majority could overthrow the present continuity of the ruling hierarchy within the League.

Oh yes, there will be many who say, "What good is a vote; they have it all tied up." Yep, that's right, but no one has tried to change it to my knowledge, just abide with it, and continue to gripe or bury their heads in the sand and accept what is recommended.

A great deal of good things have come the way of amateur radio by the gripe system. A lot of amateurs who do the griping started out as Novices and wouldn't have a license at all if it were not for the League, so they have some good things to show in the past.

It takes a good organizer to control a giant, but it can be done and the control should be from the support team. Radio amateurs, why not put your editorial efforts into reorganization. Wayne, you seem to be able to say what should be done.

I for one will give you my support monetarily and though further agitation for this type of idea. What say, Never Say Die?

Peter S. Meacham
Waltham MA

FIELD MARSHAL THURSTON

I have recently re-subscribed to *73* because I find your editorials very thought-provoking and usually pretty much to the point. I normally do not respond in writing to editorials, but I felt compelled to do so when I read about Mary Lewis W7QGP.

I have been a supporter of Mary for about four years. During this time I have gained a lot of respect for her leadership qualities in administering the amateur radio affairs of the state of Washington; for this

CARF

Canadian Amateur Radio Federation, Inc.

CALGARY HOSTS SECOND ANNUAL NATIONAL SYMPOSIUM

The second National Amateur Radio Symposium, convened by the Canadian Amateur Radio Federation, Inc., wound up its two-day session in Calgary on October 1.

The conference, hosted by the Calgary Amateur Radio Association under the auspices of the Amateur Radio League of Alberta, made several important recommendations to the senior officials of the DOC who attended, concerning the future of amateur radio in Canada.

The more than 80 participants included amateurs representing major organizations and individual operators from all call districts except VO1, VO2, and VY1.

After a pleasant Friday evening cocktail party, the four workshops got down to business for a full-day session on Saturday, followed by a banquet, and a Sunday half-day general assembly.

The workshop on Digital and Computer Communications examined the new no-code Digital Radio Operator's Certificate in detail. John da Silva, the DOC headquarters consultant, gave the group an overview of data communication concepts. Technical discussions followed on their applicability to amateur use and the need to establish interim standards and specifications for amateur "packet radio." Asynchronous FSK was recommended for initial use for 1200 baud or below, with synchronous PSK or other techniques for higher speeds. Format recommended was ASCII with packet length of 150 characters with amateur callsigns for identification.

The working group made a number of other technical recommendations and has asked CARF to form a committee to devise protocol details.

Packet radio should be introduced slowly and deliberately, much the same as was single sideband, the group reported. The cost to amateurs should be minimal, and CARF will publish availability of surplus equipment. To get into packet radio should cost only about $150, according to the group's moderator, Croft Taylor VE3OR.

Probably of more importance to most amateurs was the work of the group on WARC '79 who heard at first hand from Ed Ducharme, head of the DOC WARC '79 planning, the status of Canadian plans as they affect amateurs. Adjustments to the Canadian position are still in progress with the objective of completing a position which will, in the view of the federal government, best meet the unique needs of Canadian radio users.

The DOC did not pursue the idea of a new band around 18 MHz because of what was termed "a lack of support from the amateurs," but is still proposing 10.1-10.3 MHz as a new band. Amateurs were advised that although the new frequency allocations may be decided upon in late 1979, it would be 1981 or 1982 before implementation of the changes would be effectively underway. The working group strongly urged the DOC to reconsider the lopping off of 200 kHz from 75 meters (3800-4000 kHz), although it would propose exclusive use for the remaining 3500 to 3800 segment.

The group was told that little world sympathy could be expected for any expansion of the present 40 meter band, but a proposal to reduce it to 6.9-7.1 MHz exclusive for amateur use could be a significant gain.

The exclusive slot for "packet radio" from 221-223 MHz came under fire and in both the working group and the general assembly, which heard and discussed all of the working group results, there was a unanimous reaction voiced to the DOC to let amateurs undertake their own band planning.

The DOC noted that it would consider providing space for ATV in other parts of the 420-450 MHz band other than those now authorized, because it proposes to reduce the band to 430 to 450 MHz.

The discussion in the WARC group covered a number of other frequency problems, details of which will be found in the symposium official report.

While WARC '79 will have a delayed impact on amateur operations, the recommendations of the workshop on regulations would have a more immediate effect, if adopted. It recommended elimination of the logkeeping requirement for mobile stations. The abolition of the FCC reciprocal permits for operating while in the U.S. is now being undertaken by the DOC. Special callsigns, the group concluded, should be eliminated, and the DOC headquarters will survey the regional offices to see if this step should be taken.

Clarification of the wording of the recent DOC notice concerning the new "digital" certificate and the frequency schedules was requested, especially with regard to operation in the 220-225 MHz band.

The DOC stated that all amateurs may work in that band now as before, using the modes noted in the frequency schedules (most modes, with a slot exclusive for packet radio message formats).

Recommendations to bring regulations up to date were made, such as the abolition of the requirement for frequency- and modulation-measuring devices.

In reply to a workshop query, the DOC said that the procedure in an interference complaint when the amateur set was "clean," and all efforts on the part of the amateur to cooperate with the complainant have been rebuffed, is for the DOC to write to the complainant stating that it will take no further action.

The perennial problem of local government legislating on tower matters was discussed and the DOC noted that such authorities cannot prohibit the erection of duly-licensed radio station towers as it is an area of federal control. They can, however, impose structural and safety requirements. Amateurs who sign private agreements or leases with restrictions on towers or antennas have no recourse to the DOC.

The conclusions reached in the workshop considering "certificates and examinations" did not meet with the unanimous support accorded other workshop recommendations in the general assembly.

The novice certificate was turned down by the group and the assembly. The group recommended a 5 wpm code test for persons over 55. The majority of the general assembly did not accept the idea. A proposal to extend the principle of the present 10 meter phone endorsement to 160 meters in order to encourage activity on that band met a majority approval.

A recommendation was made that the DOC be relieved of the task of code examinations, which would be delegated to amateurs approved by the DOC. It was also recommended that amateur exams be held once a month instead of four times a year as is now in force. Both ideas met with the approval of the Sunday general assembly.

In view of the flexible policy of the DOC in examining handicapped persons (for which the group commended the Department), it was felt that no waiver of examinations for the handicapped was necessary.

A move to restrict VHF phone privileges for new amateurs met with a mixed reaction from the general assembly, with about half for and half against the idea, which reflected the working group's tie "vote" in the matter.

In the general assembly, ideas were expressed that the present advanced exam be "upgraded" to reflect the state of the art, with more about VHF, UHF, and FM techniques.

Suggestions were advanced to issue the present station licenses and certificates in a card form in order to make them more practical to carry when operating mobile or portable.

A member of the general assembly noted that a "no-code" digital operator could use A1 according to schedule and suggested that Morse code for a "no-code" certificate was redundant. It was explained, however, that in this day and age, with modern technology, Morse could be sent by machine and received by machine.

Moderator for the symposium was Bill Wilson VE3NR, president of CARF. Moderators were Croft Taylor VE3OR for the Digital Workshop, Hugh Dollard VE7PB for Frequency Allocations, Art Davis VE6KT for Regulations, and Percy Crosthwaite VE5RP for Certificates and Exams. The senior DOC Regulatory Service Officer from headquarters in Ottawa was W. W. (Scotty) Scott. The DOC representatives from headquarters were Ed Ducharme, International Planning, John da Silva, DOC Systems Engineering Consultant, Vic Decloux, and Peter Fitzgerald. Regional and district offices were represented by Murray Watson, Bob Poirier, Jim Essex, Irwin Williams, Wes Garvin, and Larry Reid. Dr. Jack Belrose VE2CV represented the Federal Communications Research Center.

The meeting learned with regret that Dr. John deMercado, Director-General of the DOC Telecommunications Regulatory Service, who has been instrumental in originating these symposiums, was unable to attend due to a last-minute change in plans.

The CARF executive and those who attended are indebted to the Calgary Amateur Radio Association and the Symposium Committee members (VE6EX, VE6GQ, VE6MX, VE6AMU, VE6SA, and VE6CJC) for the interesting and productive meeting. Thanks, too, to the City of Calgary, the Prov-

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

With the cold of the Winter of '79 upon us, and all huddled around the pot-bellied stove in the shack (would you believe an IC heat sink?), my thoughts turn to aligning and peaking the equipment up for best performance. I try not to do all that by hand; it's rough on the manicure. What we will look at this month is the test equipment that helps keep a RTTY station on the air.

Let's start with the non-specialized, rf-type gear, and then work back to the TTY stuff. I hope you have a good swr meter in the line, or at least can ensure that the swr of your antenna remains reasonably flat. Notice that I say "remains." While that super quad might have been 1:1 when you put it up two years ago, one maniacal sparrow can destroy all your careful pruning. There is nothing a modern transmitter dreads more than spending a long key-down period, i.e., a RTTY transmission, fighting a high swr. Definitely not conducive to long final life! Along the same lines, your transmitter should have the facility to readily measure plate current, and some means to taper it down if it helps the output stage. Changing from 175 W to 100 W produces less than a 3 dB change in signal strength, but is much easier on the tubes.

Moving now to the RTTY side of the shack, I feel that the minimum station test gear should consist of only two items: an inexpensive multimeter and a ROTM/GV (run-of-the-mill/garden-variety) oscilloscope. The multimeter, usually referred to as a VOM, for Volts/Ohms/Milliamps, is extremely useful wherever static diagnostics are needed. This means, for example, in setting up the TTY loop to 60 mA, measuring the plate voltage or Vcc of a supply, or analyzing the terminations of an unknown piece of equipment, using the Ohms function. With the use of this rather cheap piece of gear, under $20 from Radio Shack and others, you can perform most of the diagnostics needed to keep a RTTY station up and on the air.

Where the VOM will let you down is when you have to measure some ac or audio component, or where you have to troubleshoot some digital logic. That's where the scope shines! Over the last few months we have seen many ways in which the plain ROTM/GV scope can be useful. Audio filters can be aligned and tones calibrated using Lissajous figures and a known standard, without need for a frequency counter. A scope tied onto the output of the mark and space filters of your demodulator makes a cheap and accurate tuning indicator. Again, I am not talking about an expensive instrument. Old Eicos or Heathkits that are sold at hamfests for ten or fifteen dollars are more than adequate.

There comes a time, however, when even this veritable wealth of test equipment fails you! There are many specialized RTTY items that you can spend your money on. Let's look at one and see if we can put one together. When setting up a new piece of equipment, it is useful to provide a test signal that can check out all bits of the Baudot code. You may recall that the letters *R* (01010 in binary) and *Y* (10101 in binary) will do just the trick if sent alternately (RYRYRYRYRY . . .). There are several ways to generate this signal. If one is a reasonably fast typist, and one half of a pair of twins, one can type the RYs on the keyboard while making the requisite adjustments. Unfortunately, most of us are not so blessed. A standard way to generate the RYs is by use of a short tape loop, running on the station's TD. With chadless tape, the tape may simply be overlapped, and the punched holes will interlock into a continuous tape. Punched-through tape must be glued together, but the result is the same—a continuous stream of RYs emanating forth.

With the advent of digital electronics, one feels that there must be a better way, and there is. Let's look in detail at the signal produced by an RY tape. Fig. 1 will help Illustrate. First we'll send an R, including its start and stop bits, then the Y, with its delineators. Now string them all together and what have you got? Except for that stretched STOP pulse, it sure looks like a square wave, doesn't it? Don't you wonder if sending a square wave with 22 ms pulses would produce a string of RYs? Well, it will! Now, don't get me wrong, this is *not* the best way to generate an RY test signal, and it might not *always* work, *and* I absolutely would *not* send it out over the air, but, for around the shack, it can be helpful.

A rather simple circuit, shown in Fig. 2, can be designed around the 555 timer chip to generate the signal. The frequency is about 45 Hz (remember the 45.5 baud?) and, with the components shown, the duty cycle will be almost 50%. This means that mark and space will be about equal in length. The output of this circuit is TTL level, and how you use it is up to you. It can be

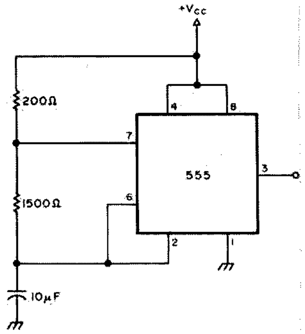

Fig. 2. 45-Hz generator.

used to drive an AFSK generator or through an optoisolator be inserted into your loop. Users of the ST-6 may be interested in the circuit of Fig. 3. This converter has a point which, when grounded, opens the loop, and the voltages are compatible with direct IC con-

New Products

THE NEW YAESU FT-227RA

If your two meter FM operation is largely mobile, you probably prefer a crystal rig which you can tune from channel to channel without taking your eyes off the road. Of course, you have to have a pretty good memory, better than mine, to remember what repeater is on what channel.

About a year ago, Yaesu introduced the FT-227 "Memorizer" which allowed you to select a channel and automatically return to it when desired.

Those folks at Yaesu know how to gild a lily, for they now have announced their FT-227RA. It is quite similar in appearance to the earlier model, which, by the way, is not being discontinued at this time, as it sells for less money. The "deluxe" version provides an expanded memory capability as well as is able to scan the entire band up or down as you choose. This dandy idea is accomplished by pressing the UP or DOWN button on the microphone. The scanner will search for a busy or clear channel, as desired, or will scan indefinitely until halted by a press of the PTT switch on the microphone. Because of the various functions performed by the microphone, it is a specially-designed unit and has a 6-pin connecting plug (supplied).

There are four memory positions in the FT-227RA. Three are for simplex frequencies, designated M1, M2, and M3, and one is for a repeater frequency, M4. By punching in your pet frequencies before you head for the freeway, you need not even bend over to read the transceiver while driving, as it is now accomplished by the microphone buttons.

This makes it one of the safest of mobile radios. When you press the UP button on the mike, it will cause a shift of 10 kHz upwards, or vice versa, if you press the DOWN button. Holding the button down will cause the unit to continue scanning in either direction as just described.

If you place the scanning switch in the BUSY position, it will cause the scan to be halted whenever the squelch is tripped by a signal on the frequency being scanned. Placing the switch in the CLEAR position will cause the scan to be halted when the receiver is muted (no signal present). When the optional tone squelch is used, the scan will be halted according to the condition of the main squelch, not the tone squelch.

One may creep up or down the entire two meter band by 10-kHz steps simply by pressing the UP or DOWN button on the mike. Or, if you hold either button down, the scanning steps are automatic.

Frequency readout is by means of bright red LEDs which are easily seen in an automobile even on a bright sunny day.

Your pet repeater can be stored in the memory prior to use of the transceiver by storing the repeater uplink (input) frequency in channel M4, and then rotating the dial to the repeater downlink frequency. With the MR switch off, you will now be transmitting on the memorized frequency, but receiving on the dial frequency. Storing repeater or simplex frequencies does not entail getting into the "innards" of the unit. It is simply a matter of dialing up what you want and pressing the memory button. Of course, this must be done, if you so choose to operate this way, each time the set is turned on, as the memory storage is not permanent.

The FT-227RA looks very much like the FT-227, with the exception of some added switches and buttons for the memory functions. You also have the usual 600-kHz up or down switch for normal repeater operation. A switch on the bottom of the unit allows you to operate with either of two power outputs, your choice of one Watt or ten Watts.

Tone squelch is offered as an optional accessory; it is a simple two-minute installation which can be made by anyone. With very few fellows and gals needing this feature, at least as the case is in California, it does shave the cost for the customer in a highly competitive market. Of course the FT-227RA has all the usual goodies we've come to expect in FM units, adjustable squelch control and an "S" meter that serves for the received as well as transmitted signal. The FT-227RA retains all of the niceties of the FT-227 while adding all those "Gee, I wish they'd have done this" items which you hear hams talk about after looking at a new piece of gear.

A mounting bracket is supplied for mobile use, as well as one to be used if you operate the equipment as a base station. The base station bracket slips under the transceiver to elevate the front of the unit. Power required is 13.8 V dc plus or minus ten percent. It will operate as a base station with the usual 12 V dc 3 Amp regulated power supply.

Operating the equipment is a pleasure, and once you have the knack of it, it is about as safe a piece of transmitting gear as you can have in your car, as it does so many things which would otherwise require you to take your eyes off the road to accomplish. Say, come to think of it, why didn't Yaesu design this rig so that it would audibly tell you what frequency it was on? Then we wouldn't have to look at it at all.

As a final comment, Yaesu has announced that the FT-227RA may have four repeater memory channels if you desire. A conversion kit is now available and the mod is simple to do! *Yaesu Electronics Corp., 15954 Downey Ave., Paramount CA 90723, (213)-633-4007.* Reader Service number Y1.

NEW AMATEUR LINEAR AMPLIFIER FROM DENTRON

DenTron Radio Company is proud to announce a revolutionary new linear amplifier for the amateur frequencies, the new GLA-1000. Powered by four D-50A (6LQ6) final amplifier tubes, the GLA-1000 is rated at 1200 Watts PEP SSB and 1000 Watts CW input with features like a reverse scale black-out multimeter for monitoring of critical currents and voltages, complete compatibility with any exciter or transceiver, front panel bypass, transmit indicator light, and a built-in relative power monitor for easy tune-ups. The GLA-1000 is super compact, ideal for portable or fixed operation, shipped set up for 117 V ac mains, and has 80 to 15 meter frequency coverage (covers most MARS frequencies just outside the amateur bands). FCC type acceptance has been granted. The GLA-1000 is now available at DenTron dealerships worldwide. *DenTron Radio Company, 2100 Enter-*

THE AED ELECTRONICS FT-227R SCANNER

I recently acquired an FT-227R 2 meter rig. While this is an excellent rig on its own merits, one of the major factors influencing me was the availability of a good, inexpensive scanner for it.

Within days of getting the rig, I got a scanner in kit form, and installed it in the rig. It worked very well—exactly as advertised. For my $34.95 (plus $1.50 for postage), I got a mailing pouch well-packed with goodies. There are some 35 components in all, including 2 ICs and a glass epoxy circuit board. Right off, I was favorably impressed by the double-sided board with silk-screened component locations. This impression was confirmed by the high quality parts and the inclusion of sockets for the ICs.

Assembly took me about three and a half hours. This may be the all-time slowest record for doing the job, but when I work inside a brand new half kilobuck (in Canada) radio, I work verrrrry carefully!

The kit went together very easily, with no hassles. For a change, all of the parts fit where they were supposed to and the holes were drilled out to the right size. Other kit builders would be well advised to use a micropoint iron, as there are a lot of components packed into a small space. The circuit board measures about ½ inch by some four inches in length, so there's not a lot of room for error.

From the scanner board there are 11 wires going to various parts of the radio. The instructions are very clear, and there is no danger of putting the V+ to ground. The instructions themselves are much in the Heath tradition, well done and very clear. The only difference I noticed was that resistors are referred to by their values instead of by color. It's nice to know that someone still has confidence in us hams.

The scanner fits right inside the radio, along the side rail of the chassis as seen from the front. The only sign that the radio has been modified is the small toggle switch sticking out of the mike.

You could restore the unit to absolutely stock condition for the price of a new mike case. Instructions on how to modify the mike are included with the kit, along with the switch. For those who use the Drake TT mike, instructions are included for it as well. A nice touch, I thought, especially since I had one and used it with the 227R.

The kit comes with a complete schematic and board layout, so in the unlikely event that something goes wrong, a look at the circuit and a study of the theory of operation will make it easy to fix.

How does it work? Very well. It is, in fact, more of a sampler than a scanner as we usually know it. When you flip the switch on the mike to scan, it scans the band in 10-kHz steps until it locks onto a signal. It will then pause there for 3 seconds before it resumes scanning. This means that you can eavesdrop all over the band without lifting a finger. When you hear something interesting, you just flip the switch to the operate mode and the rig is ready to transmit.

This feature means that those repeaters which stay on the air using a tone to indicate that the timer has recycled won't cause your scanner to lock up on them. Both the frequency range and the delay are programmed by the user. You can cover the whole band or any portion of it in 1-MHz increments. Mine is set to cover from 146 to 148 MHz, as there is almost no activity below 146 here.

The scanner operates in conjunction with the digital readout of the 227R, so you always know where you are. If you disconnect the antenna, it takes about 8 seconds to go from 146 to 148 MHz. Once it hits the high limit, it starts back down again. The 227R has a very sensitive squelch circuit, so it locks up on any signal which is audible. Since the device uses CMOS circuits, it draws negligible current from the radio.

Frankly, AED Electronics makes a fine product. I have one of their scanners for the IC-22S in the car, and have been very satisfied with it. The new one for the 227R, with its digital readout, is even better. Locally, this rig has taken the market by storm, and almost everybody has a scanner as well. I've heard no complaints at all. My only concern is that AED Electronics can't be getting very rich selling so much product for this price. *AED Electronics Ltd., 750 Lucerne Road, Suite 120, Montreal, Quebec, Canada H3R 2H6.* Reader Service number A60.

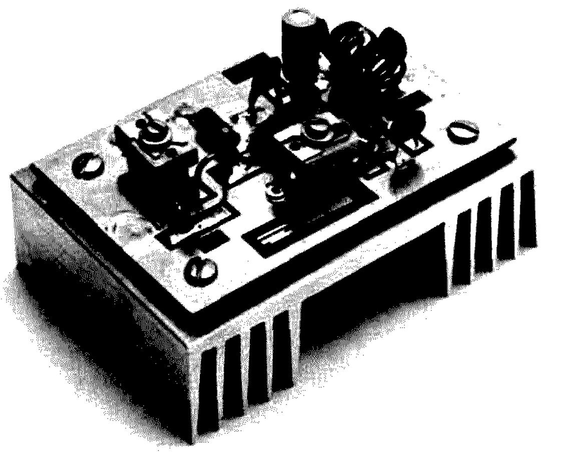
RF POWER LABS INTRODUCES MODEL V350 AMPLIFIER

RF Power Labs, Inc., is proud to announce the release of their newest amplifier, Model V350. It is a ¾-kilowatt dc-input all-mode VHF amplifier designed for base station and repeater use.

The V350 amplifier is designed for the radio amateur, but can be used on special orders over 5 MHz bandwidth, from 135 to 170 MHz. It is capable of producing more than 350 Watts of rf output power into 50 Ohms when driven with 10 to 15 Watts. The amplifier weighs only 52 pounds, including the built-in ac power supply.

For continuous duty operation, the F135 (115 V ac) or F235 (230 V ac) fan kit should be used.

For more information, contact *RF Power Labs, Inc., 11013-118th Place N.E., Kirkland WA 98033, (206)-822-1251.* Reader Service number R27.



Two meter amplifier kit from SST.

SST A-1 2 METER AMPLIFIER KIT

SST Electronics has added a 2 meter amplifier kit to their line of amateur radio equipment. The SST A-1 amplifier kit provides 15 Watts of output with 1 Watt in.

The SST A-1 includes everything necessary for a complete amplifier. A drilled G-10 epoxy solder-plated printed circuit board (2" x 3") makes assembly easy (approx. ½ hr.) with the comprehensive instructions. A large heat sink keeps the TRW power transistor cool. For ease of assembly, the coils used in the SST A-1 are pre-wound.

The SST A-1 is short- and open-protected—not damaged by high swr. Top quality components are used throughout. It is compatible with all 1-3 Watt 2 meter transceivers. The SST A-1 sells in kit form and also wired and tested. Instructions are included for a carrier-operated relay.

All SST products carry a 1-year unconditional guarantee and may be returned within 10 days for a full refund if you are not satisfied for any reason. To order, call (213)-376-5887 or

The Italian Freq Generator

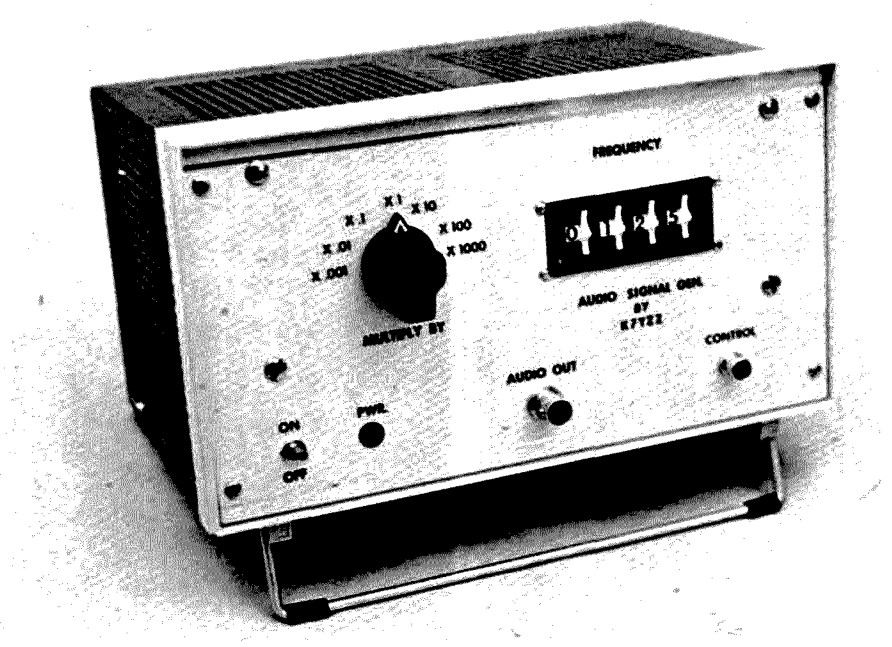
—from Bologna to you

A few years ago, this generator's qualities were found only in expensive, lab-type gear.

Louis I. Hutton K7YZZ
12235 S.E. 62nd Street
Bellevue WA 98006

During my recent visit to Sr. Franco Fanti I4LCF's ham shack, I was looking over his latest issues of an Italian electronics magazine called *CQ Elettronica*.[1] In the May, 1977, issue, I found a very interesting article on a phase locked digital signal generator.[2] I obtained a copy of that article and laboriously translated the major portion of it to get an idea of what the author, Sr. Mario Scarpelli I6THB, had to say regarding the unit. This looked to me like it was just what I needed in the way of a home-brewed signal generator to replace my aging Heathkit AG-1 audio signal generator.

An undrilled, blank PC board was obtained through I4LCF,[3] and a model was constructed in my shop. The generator provides a square wave from 1 Hz to 9.999 MHz at a TTL output level. The signal may be switched on and off through the control input port.



Circuit Description

The digital signal generator consists of six basic components as shown in the block diagram (Fig. 4). The circuit is basically a phase locked loop design with the oscillator searching through its frequency spectrum until it finds the frequency selected in the programmable counter. At this point, the loop locks. To expand the range of the unit's frequency coverage, I6THB added a logic detector circuit that enables the voltage-controlled multivibrator to switch to a different frequency range by changing the value of the frequency-determining capacitor.

The reference oscillator consists of a 1 MHz crystal oscillator, X1 (7400), with three frequency dividers, X2, X3, and X4 (7490). The resulting output frequency of 1 kHz from the divider is

used as a reference signal in the phase detector, X13 (MC4044).

Four thumbwheel binary-coded decimal (BCD) switches are used in combination with four 74192s, X5, X6, X7, and X8, dividers to provide a programmable counter. The four 7400s, X9, X10, X11, and X12, are buffer/inverters to provide the proper TTL state to the inputs of the 74192 dividers. The thumbwheel switches cover an input range of from 0000 to 9999. The output from the programmable counter is connected to the phase detector, X13.

The frequency range logic detector consists of X15, X16, and X17. This circuit is connected to selected segments of the BCD switches so that, between 0000 and 3399, the VCM frequency-determining capacitor is 133 pF. From 3400 to 9999, the capacitor is reduced to 33 pF by the switching relay, RY-1.

The phase detector, X17 (MC4044), compares the reference oscillator signal with the output signal from the programmable divider and converts this to a dc voltage level proportional to the phase error. This error voltage is fed to the input of the VCM, X14 (MC4024), to drive or hold it to the frequency displayed on the thumbwheel switches.

The output of the VCM is connected to the input of the programmable counter to complete the phase locked loop circuit. The output signal is also connected to the input of the output frequency selectable divider chain consisting of X18, X19, X21, X22, X23, and X24 (7490). The MULTIPLY-BY selector switch is used to expand the digits appearing on the thumbwheel switches into the desired frequency. For example, 2125 appearing

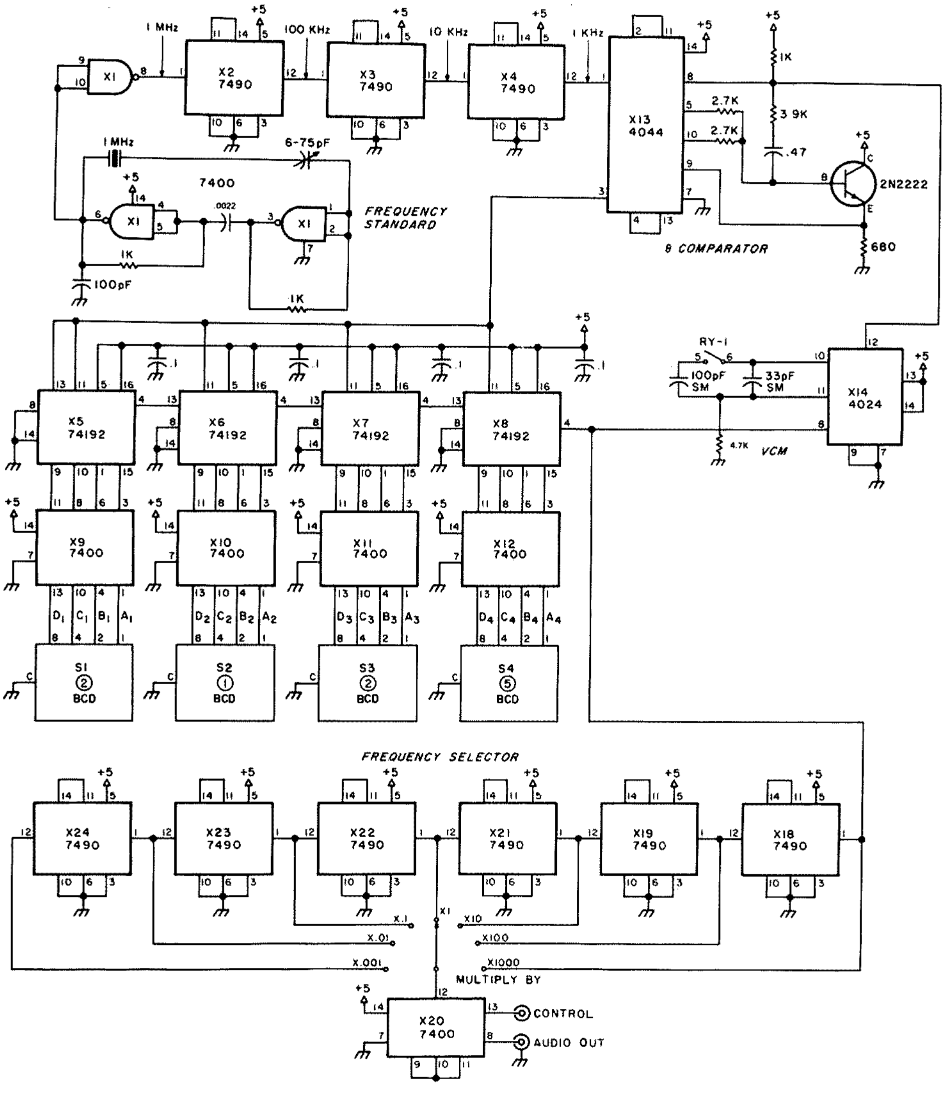


Fig. 1.

on the thumbwheel switches can, by proper MULTIPLY-BY selection, provide 2.125 MHz, 212.5 kHz, 21.25 kHz, 2125 Hz, 212.5 Hz, 21.25 Hz, or 2.125 Hz.

The control function is provided by the IC X20 (7400). Grounding the CONTROL input will inhibit the output. For example, if the CONTROL input were fed a square-wave signal of long time constant, the output would be keyed on and off depending upon the duty cycle of the signal on the CONTROL input.

Construction

The PC board I obtained from I4LCF was 8 by 5 inches and was not drilled. I built two mounting brackets from aluminum to hold the board at right angles from the front panel

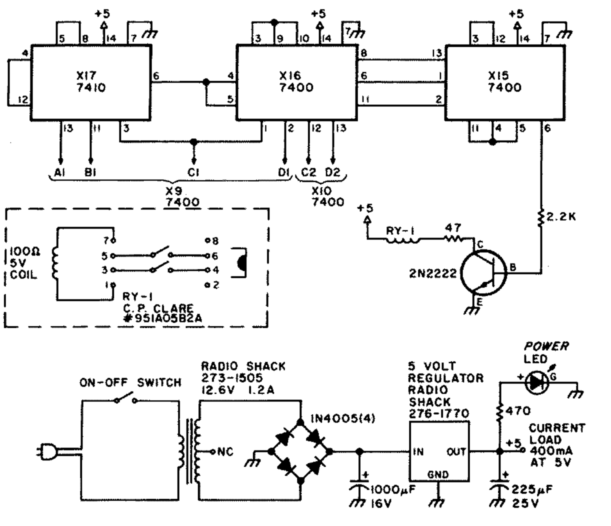

Fig. 2. Automatic switching circuit for VCM (top) and the power supply (bottom).

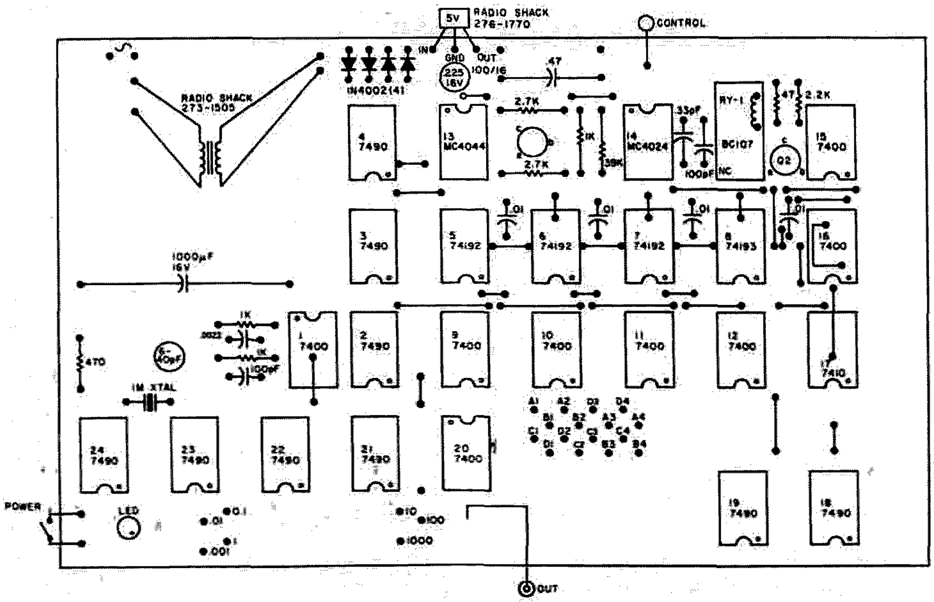

Fig. 3.

of the cabinet. The cabinet is Radio Shack part number 270-281 and is 5-7/8" by 9" by 4-7/8". The four BCD thumbwheel switches were purchased from a local surplus house, but may be ordered from Circuit Specialists Co., P.O. Box 3047, Scottsdale AZ 85257. You will need two of the end plates, part number 435245-2, and four of the BCD switches, part number 435308-2. If you buy your BCD switches at a surplus store, be sure they are coded as shown in the truth table.

The relay, RY-1, also took some doing to locate. From the photographs in the original article, I was able to get an idea of what it was, but the details in the write-up were pretty vague. I finally located a relay that seemed to meet the requirements and am happy to report that it works in the circuit just fine. The relay is made by C. P. Clare and is their part number 951A05B2A. I was able to buy it from the local branch of Almac/Stroum Electronics.

The original layout of the unit in *CQ Elettronica* had the 5-volt regulator mounted on the back of the cabinet. I had an LM309 in stock and used it mounted on the side panel holding the PC board. The original layout also had the power transformer mounted on the PC board. I mounted mine on the same bracket holding the 5-volt regulator, as shown in the photographs. The transformer is a bit oversize, as the circuit draws 400 mA at 5 volts.

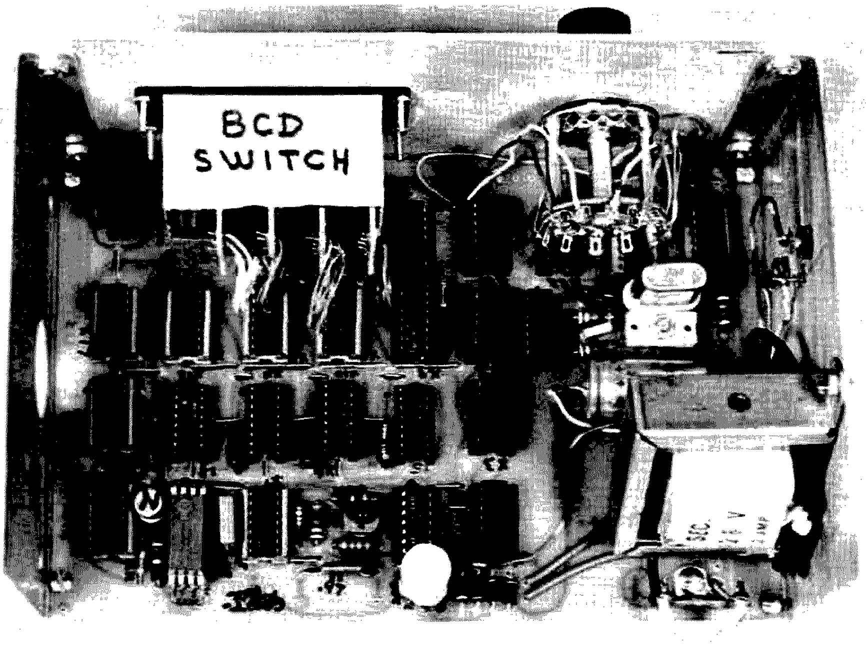
After the PC board is drilled, the jumpers should be installed before the IC sockets are soldered to the board. The layout of the sockets, jumpers, and components is shown on the drawing. The HEPC3806P is the equivalent of the MC4044. The HEP3805 is the equivalent of the MC4024.

Testing of the finished unit was done in a series of steps as follows. When the board was wired, the IC for the 1 MHz oscillator was inserted along with the crystal. Power was applied, the 5-volt bus checked, and a scope probe connected to pin 1 of X1 to confirm that the oscillator was working. It was monitored on a communications receiver at 10 MHz to zero beat it with WWV.

Then the X2, X3, and X4 ICs were inserted, and, again, the power was applied. A counter was connected at each test point (pin 12 of the 7490) to be sure that the divider chain was working. Sure enough, I found that I had used a bad 7490 from my junk box.

Next, the MC4024, X14, was inserted and, again, the power applied. A counter was connected to pin 8 to be sure that the VCM was oscillating. It should be oscillating somewhere between 10 and 15 MHz. Ground pin 12 of the VCM and the frequency appearing on pin 8 should change from 10 to 15 MHz to around 3 MHz. That checks out the VCM frequency shift by varying the input voltage.

The relay, RY-1, is checked next. Install the remainder of the ICs, apply power, and, while using a VOM, monitor pins 5 and 6 on the relay for closure of contacts as the thumbwheel switch in the first



digit is switched from 3 to 4.

The final check made after assembly is to monitor, with a counter, the oscillator frequency as it appears at pin 1 of X18. Then follow that frequency down through the MULTIPLY-BY divider chain, looking at pin 1 to see if it has been divided by 10 at each stage of the divider.

It has been noted during testing that, when the unit is first turned on from a cold start, it takes about three minutes before the VCM settles down and is locked into the oscillator. The accuracy of the output frequency versus the digital thumb switch setting seems to be very good (plus or minus 1 to 2 Hz) on the audio ranges up to several hundred kHz. In the MHz range, it may be off as far as several hundred Hz, according to my counter readout, which is still very acceptable for home-brewed equipment construction.

Conclusions

Although the unit as now constructed connects the output to a 7400 buffer, it was suggested in correspondence by I6THB to I4LCF that, if the builder wishes to provide more isolation and a better output load source impedance, an emitter follower circuit could be used with a 600-Ohm emitter resistor in the output. A transistor should be used that will handle up to 10 MHz signals.

I have had the unit in operation now for over ten months, and it has not given me any problems at all. Once the initial warm-up and lock-on has occurred, all that is required to get a particular frequency between 1 Hz and 9.999 MHz is to dial in the frequency.

I will try to answer questions from those who build this unit if I can and if they will please enclose a self-addressed stamped envelope. ■

Happiness is a WE-800

—proud owner loves his Wilson

If 2m FM is your bag, this is your rig.

C. A. Kollar K3JML
1202 Gemini St.
Nanticoke PA 18634

Recently, Wilson introduced a new concept in two meter FM rigs—the WE-800. This compact unit is an all-around synthesized rig that can be used portable, mobile, or as a base. Its features include: 144 to 148 MHz coverage in 5 kHz steps, switchable 1- and 12-Watt output, 600 kHz up-down offset with two other positions available for other than 600 kHz, five priority channels on the front panel, and a meter light switch on the rear panel to conserve battery power.

After hunting around for a couple of months trying to locate a distributor who had one in stock, I finally located one, ordered it, and eagerly awaited its arrival. When it arrived, I installed a newly-purchased and -charged set of nicads and turned it on. My first impression was that the received audio (emanating from the combination speaker/mike) sounded extremely hollow and tinny. Figuring that the effect was because of the small size of the speaker in the speaker/mike, I continued with the test somewhat disappointed, and made a call on the local repeater. The subsequent QSOs revealed that the transmit audio was full, crisp, and clear. Apparently, there were no transmit problems, although that hollow receive audio bothered me. After four or five short transmissions, my fears were realized when, upon releasing the mike button, I was bombarded with a raucous squeal. The received audio section was oscillating! I made a call to Wilson to explain the problem, and George Tennell advised me to ship it back. Wilson had it in the shop only one day and it was on

Fig. 1. Front panel.

its way back. If it wasn't for the twenty-four days it took UPS to get it to and from Nevada from Pennsylvania (bad news), it would have taken me a lot less than the nearly four weeks it was gone to get it back.

After carefully unpacking the repaired unit, I turned it on and listened to a QSO in progress on the local repeater. I was pleasantly surprised at the nice audio coming from the speaker/mike. What a difference! Leaving the unit on and monitoring all day wore the batteries down pretty well, but there was no trace of audio oscillation. Wilson had done a great repair job on the radio. I've had it a month now and the WE-800 still performs beautifully. My enthusiasm for this unit prompted me to write this review.

Front Panel Switches

Frequency selection is accomplished by a three position digi-switch which can be seen in the photo located at the left of the front panel. This unit covers 144 to 148 MHz in five kHz steps (10 kHz/step on the digi-switch, plus an extra five thrown in by flipping the kHz toggle to 5). Additionally, a six-position switch located on the right side of the panel can be used to choose five "priority" channels which will be used frequently. With the switch in the "dial" position, any frequency dialed in on the digi-switch will be heard. In positions A through E, any one of five preprogrammed channels will be activated. Please note at this time that the *receive* frequency is always dialed in on the digi-switch, or programmed in on the six-position channel switch. Transmit frequency is offset up or down from the receive frequency or made the same as the receive frequency by operating the R/U-S-R/D toggle. R/U is used for 147 MHz repeaters, S for simplex, and R/D for 146 MHz repeaters. With the frequency coverage of the WE-800, you will have instant access to any repeater which may start up in the new repeater subband.

Programming priority channels is accomplished with diodes. See Fig. 2. As you can see, channel E is programmed for 147.18 (MHz—4, 2, and 1; 100 kHz —1; 10 kHz—8; and 1 kHz—0). 1N914 or equivalent diodes are recommended but, whatever you use, they *must* be small. The programming board is tiny and unless the diodes are small, they won't fit. Also, a subminiature soldering iron is a must. Without one, you wind up with as many solder bridges as solder joints.

The Hi-Off-Lo switch is operative only when using an external power source. When on internal batteries, either the Hi or Lo position will give you 1-Watt output. When on an external power source, the switch becomes operative, and selection of 1- or 12-Watt power levels is possible.

Rear Panel Switches

The rear panel switches are slide switches which provide a number of functions as will be explained. However, there is one big problem with them—they protrude too far from the chassis. I found that whenever the back of the radio brushed against something during normal use, the switches would be moved to some position I didn't want. I had the radio only two hours when I solved that problem by snipping off ⅔ of their length with a pair of diagonals. I've had no problems since that time and can still operate the switches easily.

The antenna select switch is the switch mounted nearest the SO-239 connector on the rear panel. See Fig. 3. This handy switch allows you to select from an antenna connected to the BNC connector on the front (rubber ducky, etc.), or from an antenna connected to the SO-239 on the rear. This comes in handy when going from portable or mobile to base.

The lamp switch in the "on" position illuminates the S/RF meter on the front panel for easy meter viewing. When on internal batteries, it can be kept off to prolong battery life. Power consumption is reduced considerably with the light off in standby. Squelched receive current with the light off is 50 mA and with the light on is 110 mA.

The power switch lets you select from an external power source or internal nicads or enables you to charge your batteries from whatever you have connected to the external power connector (power supply, cigarette lighter, etc.). The problem with this arrangement is the inability to monitor while charging batteries. This is a distinct disadvantage because it puts your radio completely out of service for 12 hours in order to recharge your batteries. I guess this isn't too bad if you can make certain your batteries go dead only before you're ready to go to bed. The other disadvantage is the design of the "charging system" itself. No provision has been made for current limiting, so if your batteries are very low, and you charge them from your cigarette lighter or power supply, the batteries draw a hellacious amount of current for a while until they charge high enough to begin drawing a reasonable amount of current. Back to the drawing board on this feature, Wilson! See Fig. 4.

The RPT switch with positions marked "600 kHz," "A", and "B" is a nice feature of this rig. This switch controls how much the transmit frequency is offset from the receive frequency you have set up on the front panel. In the 600 kHz position, the standard repeater offset is utilized. In positions A and B, any one of two other transmit offsets chosen by you is

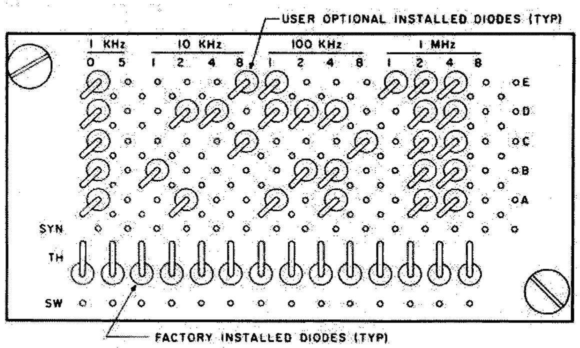

Fig. 2. Diode matrix frequency programming board (viewed from the top).

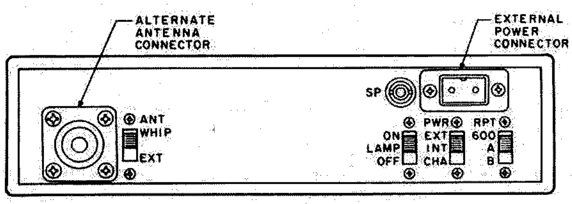

Fig. 3. Rear panel.

used. Transmit offset from receive frequency other than 600 kHz is accomplished by plugging the proper crystal in the transmit local oscillator in one of four possible positions (Pos. A—R/U; Pos. A—R/D; Pos. B—R/U; Pos. B—R/D).

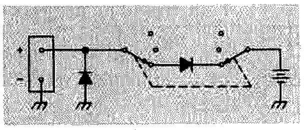

Fig. 4. Charge circuit.

Finally, a rear jack is provided for using an external speaker. Frankly, I can't get too excited over the speaker/mike and I think Wilson could have found a way to build in a speaker. However, the audio coming from the speaker/mike is surprisingly good.

Miscellaneous

Wilson's approach to the low-power position is to incorporate a separate 12-Watt amp which is switched in only when external power is used (if the Hi/Lo switch is in Hi). This was a wise approach and accounts for the low (290 mA) current drawn when operated in the 1-Watt position. This is a much better scheme than used in some other multi-power rigs which force a 10-Watt amplifier stage to run at 1 Watt, with resulting higher current drain resulting in lower efficiency. A 50-mA squelched-receive-current battery life is approximately 6 hours when monitoring a repeater of normal activity.

Conclusion

All in all, for someone looking for a 2 meter rig they can use portable, mobile, or base, the WE-800 is a wise choice. It has all the features you're looking for in a 2 meter synthesized rig, plus small size. It should provide years of enjoyment. ■

Looking *West*

from page 21

own users and say "to hell" with everyone else. The fallacy of this lies in the fact that making an open system into a private system will not make our jammer go away. He does not need the "secret tone" to jam—only the ability to capture the repeater receiver without the tone, which in effect shuts down the receiver. He won't be repeated, but neither will any user. A definitely ineffective solution.

The best suggestion to date came to me in a two-part conversation I recently had with NBC News correspondent Roy Neal K6DUE. It started one night on the phone and was completed the following week in Roy's office at the famous NBC peacock factory in Burbank. Roy's job has him traveling more than most of us, and therefore he is in a position to evaluate things that we might never get to see firsthand. Roy has some definite feelings on this subject, and his views make a lot of sense to me.

Roy's basic philosophy is that the big cities, where the real problems manifest themselves, should take a look at how the more rural areas operate. In most non-urban areas, repeaters are calling channels, places all amateurs monitor while they await a call. Should they be paged by some fellow amateur, they usually choose a simplex channel and QSY. Only under marginal conditions are repeaters used to carry on long-winded discussions. In the "outlands," repeaters serve the distinct purpose for which they were intended. It is rare that one gets jammed, and in those infrequent instances, the jamming is never given any form of recognition.

The big cities are another story altogether. Hour after hour, repeaters are tied up with useless conversation between groups of amateurs living within simplex range of each other or between mobiles half a mile apart conversing through a repeater twenty miles away. It's rare when you hear one station take another to a simplex channel to continue a QSO. It's not uncommon to hear stations a mile or two apart break an existing conversation in order to obtain the system for their own QSO—when they have no need for relay communication whatsoever.

Roy therefore feels that the best way to frustrate a would-be jammer is to simply go away when the repeater gets jammed. Don't fight it—that only gives the intruder the audience he seeks. Simply take your QSO off to another repeater or (preferably) to simplex. If your area is being heavily harassed by the jamming crowd, stay off the repeater(s) and thus take away their audience. Even if the jammer catches on and takes to harassing you on simplex, a carefully arranged schedule between you and those with whom you wish to speak will frustrate the life out of the sickies in our society. Even if it's necessary to purchase an amplifier to ensure constant communication, this is a far better approach than sitting on a repeater trying to talk over a healthy jammer. If enough users of harassed systems take this approach, and the band gets filled with simplex, a jammer will be very hard put to continue his antics. In the process, many will discover that repeaters are not always a necessary means with which to communicate. In fact, I spend more time talking to Roy on simplex than via any mountaintop box. Try it—it really works!

THE .76ERS

A noted local amateur recently said to me: "At least the .76ers had class!" He was referring to the mid-1960s, when a group known as the ".76ers" ruled southern California FM with a "tongue-in-cheek iron thumb." That was the pre-repeater era, when only a handful of hams inhabited two meters and even fewer machines existed. Over a period of years, the .76ers had developed jamming into an art form. But being jammed was part of being a .76er, and all on the "inside" looked at it as part of the fun. (The FCC took a far different view, however.) Much of what went on on 146.76 back then was recorded for posterity in a series of articles that appeared in various publications over the years. The series was called "The Chronicles of .76," and was written by Ken Sessions K6MVH. I understand that for anyone interested in knowing what it was like back then, the series is "must" reading.

The .76ers jammed because jamming was part of being a .76er. To them it was not malicious, but just part of their lifestyle. They abided by their own unwritten rules as to who, what, why, and how. While outsiders continually chastised them for their actions, they just ignored it all and kept on having "fun." You and I would probably have been appalled if we had tuned in on .76 in those days, but our life-styles and backgrounds were totally different and we would have judged what we heard in a different light.

I mention .76 for a few reasons. First, while you and I might have judged the .76ers' actions to be improper, one clear fact is that they never went out of their way to be malicious in the sense that they would venture away from .76. There were a few occasions, but they were very rare indeed. If you happened to venture into their spectral territory, you were fair game, but if you did not like .76 and stayed away, they could have cared less about you. The only time they jammed a repeater was when one would try to set up shop on .16/.76. To this day, though many have attempted to establish such a system in the Los Angeles/San Diego rf corridor, not one has ever lasted more than a day or two. The remnants of the .76ers remain a viable force today, still strong enough to keep .76 simplex. They remain very low-key, but are far from having dissolved into oblivion.

Happy New Year!

Corrections

In my article "PCs Are Easy" (December, 1978), line 3 of column 4 on page 271 should better have read: "After the full-size *positive* . . ."

Brian E. McArthur VE3CGE
Brampton, Ontario

There is one minor error in the diagram on page 188 of "Build the Brute" (November, 1978). The gate of the SCR is shown looking at the 8 uF capacitor discharged by a 470-Ohm resistor through the 14-volt zener. The anode of S1 should also be connected to the positive output of the supply.

Explore the World of VLF

—with this simple converter

A broadband preamp makes this unit tick.

Donald T. Morar W3QVZ
3663 Hipsley Mill Rd.
Woodbine MD 21797

After looking at available VLF converter data, I embarked on a design to facilitate some VLF listening. Because it was convenient relative to the communications receiver that I planned to use the converter with, a 10 MHz i-f was picked. This removed the i-f far from many possible sources of i-f feedthrough.

The circuit shown utilizes an LM318 as a broadband op amp, providing greater than 8 dB gain from 20 kHz up to 400 kHz. The mixer utilized is a 40673 MOSFET containing internal protective diodes (not indicated in the schematic). See Fig. 1. The local oscillator (LO) employs a 2N5458 FET as a rather conventional crystal oscillator operating at 10 MHz. LO injection is controlled by C_{inj} and tuning by C_t, although, of course, there is some interaction between the two capacitors.

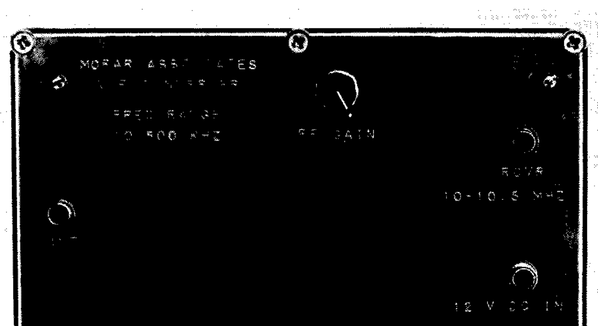

Photo A. Front panel, showing antenna input on left, 10 MHz out in the upper right, and 12 V dc input in the lower right. A tunable i-f output was added after this picture was taken (see the schematic). The tunable inductance core shaft was brought out as an operating control slightly to the right of the rf gain control. It can be seen in Photo C.

I used a low-frequency signal generator with calibrated output, and I adjusted C_{inj} for best sensitivity with a very weak signal generator output, while maintaining the LO frequency at 10 MHz. The receiver used had a tuning range from 10 to 10.6 MHz, yielding a converter tuning range from zero beat to 600 kHz. Other appropriate frequencies could be employed to accommodate the particular receiver to be used. It is recommended that the LO frequency be kept relatively high, say, at at least 40 meters, to ameliorate i-f spurious responses as previously mentioned. If a 40 meter ham band receiver is to be employed, simply use a 7.0 MHz crystal and retune the LC tank in the drain circuit of the 2N5458 FET. It may be necessary to add a bit of fixed capacitance in parallel with the existing 3-30 picofarad trimmer in order to tune down to 7.0 MHz.

The lower frequency limit of usability is, at present, about 10 kHz because of the 10 MHz LO feedthrough into the receiver. I think that a new layout would have to be made to further preclude this problem. A two-section lowpass filter is utilized on the input to the LM318 to preclude cross-modulation with strong signals in the broadcast band and above. The filter rolls off 6 dB by 500 kHz and is 20 dB down

at 750 kHz.

The converter was tried with several antenna arrangements. The most satisfactory was a 1000-foot longwire antenna that terminates in the shack. It still left much to be desired, so a separate antenna coupler was assembled. See Photo C. This greatly improved the reduction of cross-modulation and converter-usable sensitivity. Even with the low-pass filter at the converter input, strong local stations in the broadcast band plus local 100 kHz loran signals would cause objectionable cross-modulation problems without the antenna coupler.

I am also working on a fixed tuned TRF receiver for receiving WWVB, wherein a double-shielded tuned rotatable 27"-radius loop will be employed.

With the antenna coupler indicated in Photo C, it was possible to receive WWVB at 60 kHz at this location with an S-meter reading of S9, indicating an input in the vicinity of 20 microvolts. Without the antenna coupler, it was not possible to hear WWVB at all due to spurious responses about either side of 60 kHz. The converter requires 12 volts at 12 mA.

As can be seen from the accompanying photos, the converter is built on a 3½" x 6" single-clad phenolic board, utilizing vector mini-klip pins pushed into the holes of isolated copper pads, produced by an isolated-pad-Drill-Mill tool. See Photo B. The converter is housed in a Bud CU-247 Econo-box, with dimensions of 7-25/64" x 4-45/64" x 2-7/32". The antenna coupler is in a separate box, since it came as an afterthought and would have made the dimensions and layout of the converter unduly large anyway.

Fig. 1. shows the antenna coupler converter and Kenwood R599 reciever set up and connected to the 1000-foot longwire antenna which is 60 feet high. The antenna coupler was built in a 3" x 5" x 7" minibox, Bud CU3008. See Photo C. Coils were mounted on the selector switch so as to be as mutually perpendicular to each other as possible to minimize magnetic coupling. The Arco-type 315 compression capacitor has a range of 2525 pF tight and 1200 pF at 3 turns open. Using the inductances indicated, satisfactory tuning was obtained from 20 kHz to 200 kHz. Above 200 kHz, the converter had plenty of gain connected directly to the antenna without the coupler. Cross-modulation was not a problem in this region, either. ■

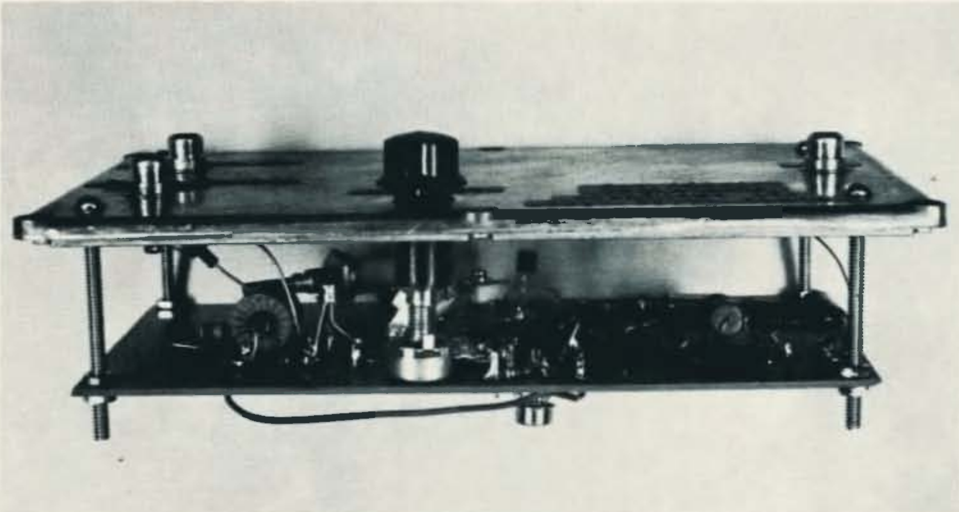

Photo B. Side (open view) of the converter showing the copperclad board and vector mini-klip construction described in the text.

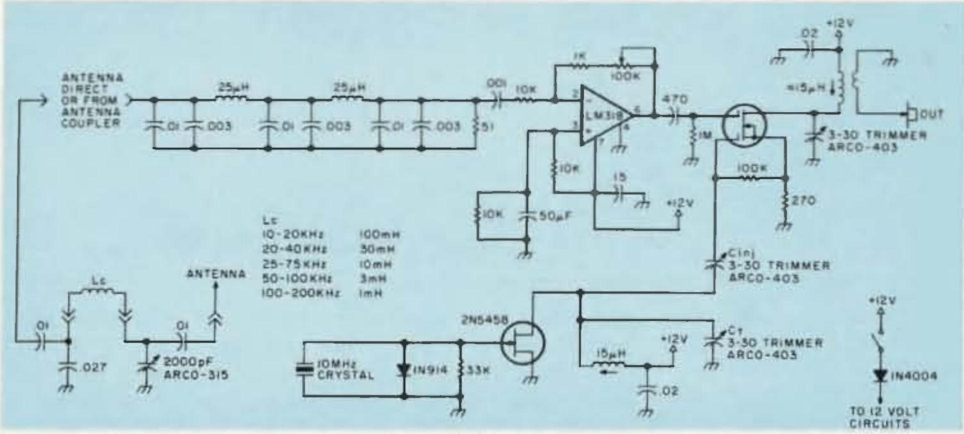

Fig. 1. VLF converter.

Photo C. The converter set up with the Kenwood R599 receiver. The antenna coupler can be seen at the top above the converter.

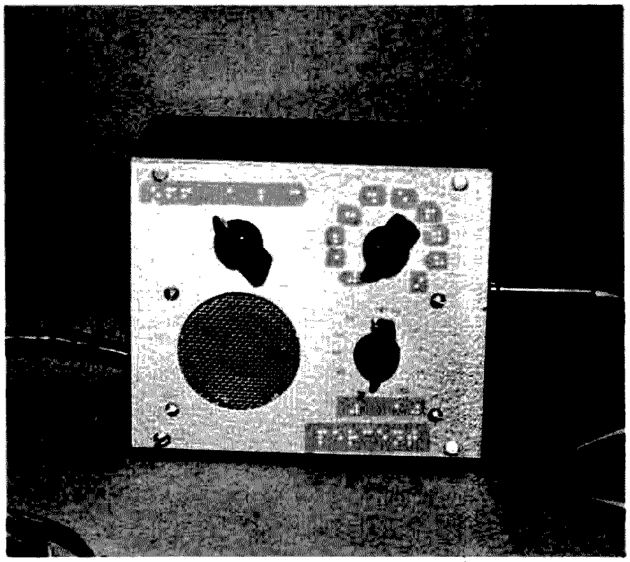
The S.H.A.F.T.

—special tuning gadget for sightless hams

You don't have to see to believe.

Burton H. Syverson K5CW
3401 Garner Lane
Plano TX 75023

Recently, a sightless ham friend of mine remarked that he had ruined the final amplifier tubes in his transmitter by exceeding the maximum plate current. I am sure that being unable to tune his own gear must be very frustrating. Like most hams, I remembered several articles relating to tuning aids for the blind. As luck would have it, a search of my old magazines did not yield much information. The idea of a voltage-controlled oscillator is not exactly new, but it is hard to beat. What articles I found, however, used this idea to tune for maximum or minimum indication.



Not finding what I desired, the search for a method of reading discrete values of current or voltage began. The method decided upon involves the comparison of a variable voltage source calibrated in percent of the full scale voltage drop of the moving coil of the meter (Fig. 1). Application of the voltage-controlled oscillator is used to indicate balance. I call the unit to be described "The S.H.A.F.T." This stands for the Sightless Ham's Aid For Tuning.

Safety is always the prime consideration in the design of any electronic gear to be used by blind operators. In order to assure the equipment case was grounded, ac operation is used. The connecting cables carry ground to the frame of the equipment whose meter is being monitored. When readings are desired using a multimeter, the shield of the connecting cable is used as an electrostatic shield only, because of the nonmetallic case. For the operator's safety, use of a multimeter should be restricted to resistance and low voltage measurements.

One of the features of this unit is that it can be used with three different meters (i.e., multimeter, plate current meter, or ratiometer). Operation of the unit is quite simple. Referring to the schematic diagram (Fig. 2), it will be noted that zener diode CR1 holds the voltage of battery B1 at 3.9 volts. This is applied to a series resistance network so that the voltage drop from the lower end of control R14 to the junction of R13 and R22 is approximately 40

millivolts. This is something less than the full-scale voltage developed across the moving coil of most meters. By use of control R14 and switch SW2, any voltage between zero and 40 millivolts may be obtained. This voltage is fed into the inverting input of an operational amplifier on IC U1. Control R14 is calibrated from zero to 10% and switch SW2 in 10% steps from 0 through 90. The settings are additive. Voltage from the moving coil of the meter to be read is fed in jack J1 through 2-conductor shielded cord to switch SW1A which selects control R1, R2, or R3. R1, R2, and R3 are used to adjust the full-scale meter voltage to the 100% setting of the R14 and SW2. The voltage across R10 is fed into the noninverting input of the same operational amplifier. The output of the amplifier is fed into null detector Q1. Q1 causes unijunction oscillator Q2 to increase in frequency whenever the output of the operational amplifier crosses zero volts. The output of the oscillator is connected to a second operational amplifier which serves as an audio amplifier. Note: The jumper connected from C2 to terminal 1 of U1 may be replaced with a suitable resistor if the constructor feels the audio level is excessive.

Due to the dc nature of the unit, the mechanical layout of parts is not critical. The size of the etched circuit board was chosen to accommodate its being fastened to the back plate of a 4" × 5" × 6" Bud cabinet (Fig. 3). Others may choose a larger cabinet for ease of construction. In my unit, switches SW1 and SW2 are rated at 1500 V dc breakdown and need not be insulated. However, control R14 is sub-mounted on a piece of vectorboard 2½" × 5" with enough clearance that the speaker frame (also on the vectorboard) does not touch the front panel. All parts (other than those on the etched board, and C3, F1, J1, and T1) are mounted on the vectorboard. Difficult to mount parts are held in place by epoxy cement. marking of the panel is done with embossed tape. Print wheels for embossed-tape writers are available with Braille symbols. Switch SW2 should be marked as shown on the schematic. Control R14 markings may be dots of nail polish with the zero and ten percent points identified with embossed tape. The in-between points may be determined with an ohmmeter connected from the contact arm to the lowest-voltage terminal of R14.

To put the unit in operation, connect a voltmeter (set to read 10 volts) across resistor R7 on the etched circuit board. Connect the meter you wish to use to input jack J1 through a suitable cable. Set R14 and switch SW2 to zero percent. With the power cord plugged in, operate switch

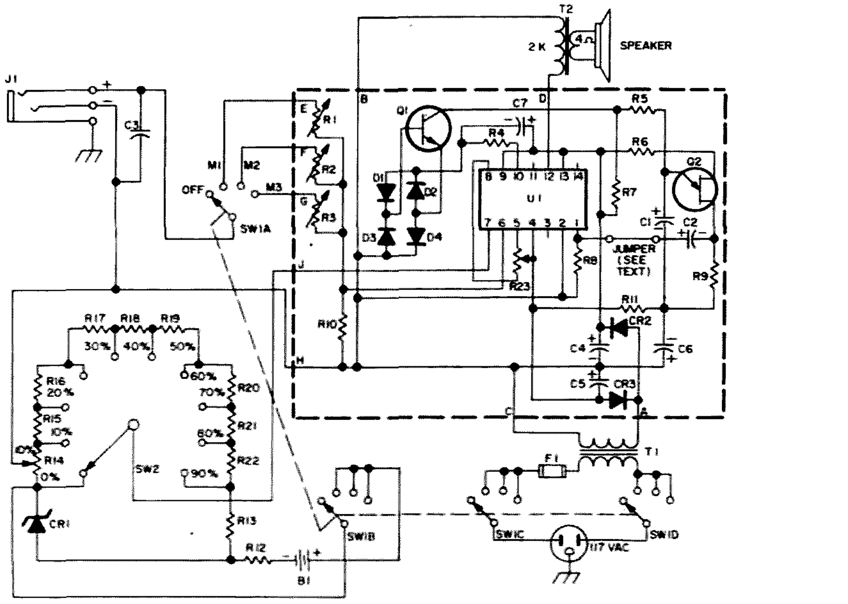

Fig. 2. S.H.A.F.T. schematic diagram.

SW1 to position M1.

A low-pitched raspy tone should be heard from the speaker. Resistor R5 may be reduced in value if a higher pitch is desired. I feel the shift in tone is more pronounced when a lower pitch is used. Adjust the offset control (R23) for minimum voltage drop across resistor R7. By external means, obtain a full-scale reading on the meter you wish to calibrate to. Observe the polarity shown at J1 on the schematic. Set control R14 to 10% and switch SW2 to 90%. Slowly adjust R1 until a point is found where the pitch of the tone peaks. Tune for the highest pitch. The same method should be used for any other meters you wish to calibrate to.

All that is necessary, now, is to provide the user with charts (in Braille) showing meter values versus percentage of the meter scale for each desired range. Due to the fact that meter scales are printed, the angular movement does not necessarily track. As a result, it may appear that the user's ability to determine the reading is no better than 2 or 3%. My tests indicate at least half of this is due to tracking error of the meter. For this reason, it is safe to assume the Braille calibration for dc voltages is a straight line function (i.e., 80% equals 8 volts on the 10 V dc scale).

This unit was not intended for ac measurements in an effort to discourage the user from trying to make readings of the commercial power line. Should this feature be desired, it will be necessary to filter the input to the unit. This will undoubtedly upset the calibration of the meter's ac ranges.

The unit shown in the photograph is a prototype and the panel markings are not identical, though similar to those shown in the schematic (i.e., 90% on SW2 is 9). Space limitations make use of ½" tape difficult. However, the Braille characters are easier for the user to identify.

Since semiconductor devices can overload easily in rf fields, trouble may be encountered when the unit is used in close proximity to transmitters. The same lead filtering methods used for TVI prevention should help. As no single solution can be expected to cure all problems, it may require some experimenting to get normal operation under these conditions.

As with any idea, it can be improved upon. At present, this design appears to be a good compromise between results and cost. The enthusiasm of two of my blind ham friends for this device made the effort most gratifying. I hope this unit will provide a means for the sightless ham to enhance his independence and more thoroughly enjoy amateur radio. ■

A Remotely-Tuned Matchbox

—ultimate operating ease

This system will tune your Matchbox from 300 feet away—or more.

Guy Black W4PSJ
12317 Hanger Road
Fairfax VA 22030

My shack is among those where the path between the operating position and the feedpoint of the antenna system poses some problems. So, I decided to locate a Johnson Matchbox in the garage, some 75 feet away, so I could use tuned feeders for a classic-dimensioned multiband antenna — 135 feet long centerfed with 42-foot feeders (see the older ARRL *Handbooks*). The rf path to the Matchbox is RG-8, and the problem is to tune and change bands on the Matchbox from the operating position.

I thought other hams would like to know how I did this, though I doubt that any would exactly duplicate the oddball collection of relays and motors that I obtained at trivial cost at various hamfest flea markets. It turns out that motorized tuning, bandswitching, tuner dial indicating, and a grounding switch for lightning protection can all be done with the commonly available 8-wire cable normally used for rotators.

I had kept my eye open for gear-head motors suitable for turning capacitors for a number of years and finally picked up a very assorted group which do the job. Any reversible motor with 2-20 rpm output and a reasonable torque capability can be used. A common type of 110 V ac motor has a starting capacitor that is connected between two of three motor connections, the third connection being connected to one side of 110 V ac and the direction of rotation being determined by connecting the other side of 110 V ac to one side or the other of the capacitor.

Another common type of reversible ac motor has four connections, two of which are interchanged to change rotational direction. Dc motors with permanent magnet (PM) fields are generally reversible merely by reversing the polarity of the dc, though others — identifiable from connections — require reversing field or rotor connections.

One of the ac motors used was actually two motors on one shaft, each good for a different direction of rotation. This unit was made by the Merkle-Korff Gear Company and was so suitable for the purpose at hand that I contacted the company.[1] My motor was their type SG-25, now supplanted by model BF, and it turns out that the company has a national network of stocking distributors and can supply motors with various rotations down to one rpm with starting torques of 10-50 pound inches; torque is important, as the rotation of many big capacitors is a stiff job. These units are perhaps more appropriate to the intended function

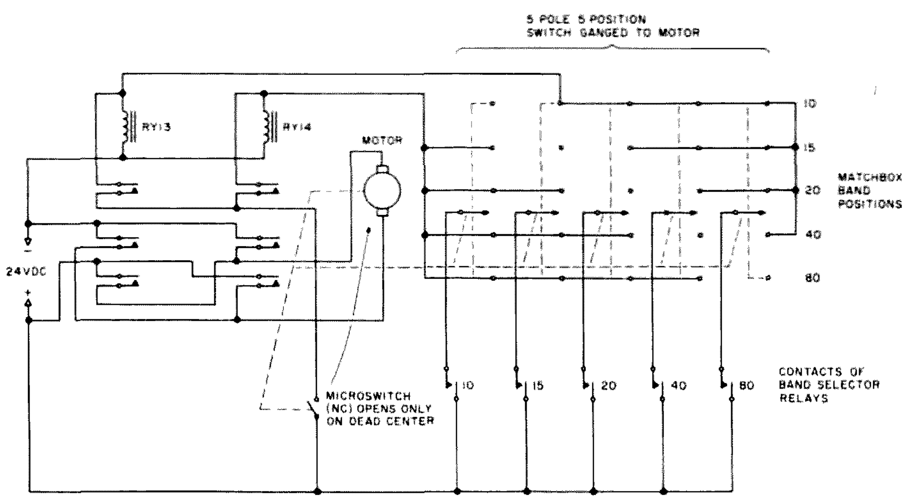

Fig. 1. Circuitry for motorized bandswitch.

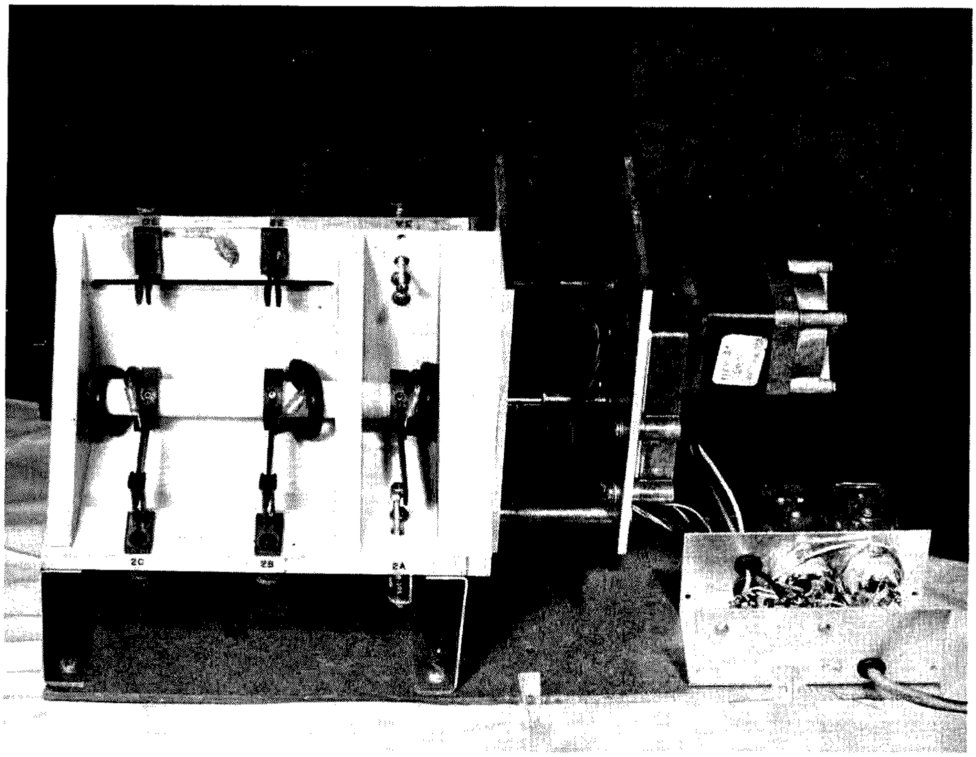

Photo A. Antenna grounding unit driven by reversible gear-head motor with limit switches to terminate rotation. Slack in the cotter pin holes lets the motor get up speed to overcome the torque required to turn the switch.

than the more elegant instrument motors manufactured by Japan Servo Co. (subsidiary of Hitachi, Ltd.).[2]

The functions which I wished to operate remotely included turning two capacitors of the Matchbox and bandswitching to any of five bands. In addition, it turns out to be essential to have an indication at the operating position of the setting of the matching capacitor. If this is once set, a vswr bridge at the operating position can be used to find the proper setting of the tuning capacitor merely by rotating it (remotely) for minimum vswr. However, attempting to tune the Matchbox without information on the setting of the matching capacitor is hopeless.

In addition to controlling the Matchbox, I added two extra functions: an arrangement for grounding the tuned feeders for lightning protection (the need for this was learned the hard way) and provision for switching the coax from the Matchbox to another antenna, which will be for 160 meters in my case, but could be anything.

Photo A shows how I adapted an antique knife-blade-type power switch obtained from a local surplus dealer for antenna grounding. While two of the knife blades switch the tuned feeders, the third activates limit switches that restrict rotation of the knife blades to a 90-degree arc by shutting off the motor automatically when the desired connection is made. Duplicating this switch should be within the capability of many hams.

Photo B shows the activating unit for the Matchbox, connected to it by angle-aluminum arms to existing screw holes of the Matchbox, which has not been permanently modified in any way. In fact, it is a simple matter to detach this unit, say for Field Day, and restore the Matchbox to its original condition. What is seen is a PM-field, dc gear-head motor of uncertain vintage operating the tuning capacitor on the left, the double Merkle-Korff motor on the right driving the matching capacitor via an internally-toothed belt (similar to an automotive timing belt), a selsyn indicator-transmitter for the matching capacitor, two boxes containing controlling relays and other associated parts, and an assembly to take care of the bandswitching function. Dials have been replaced by bushings with projecting wire indicators, for use in local adjustment.

Now, as the tuning and

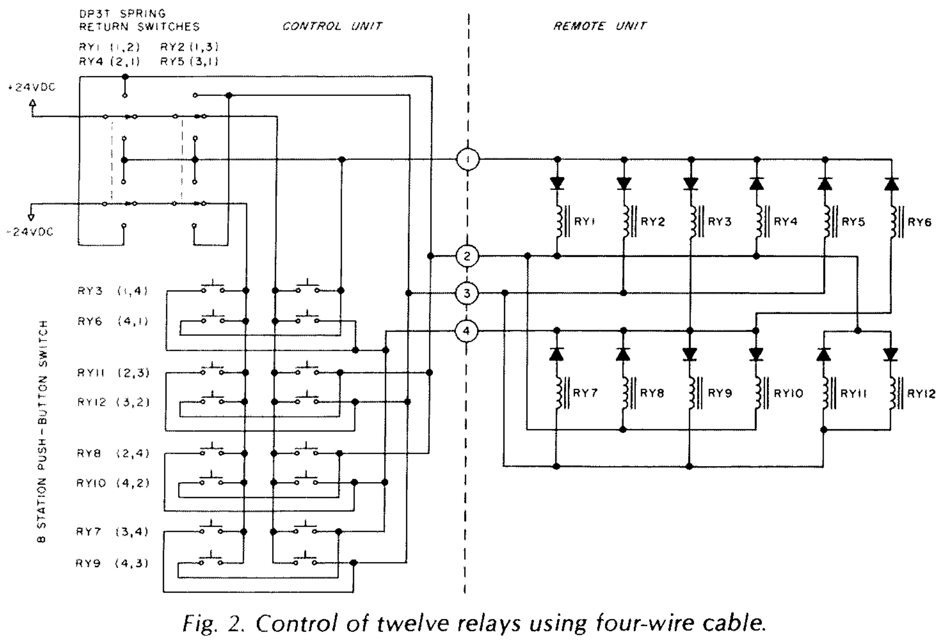

Fig. 2. Control of twelve relays using four-wire cable.

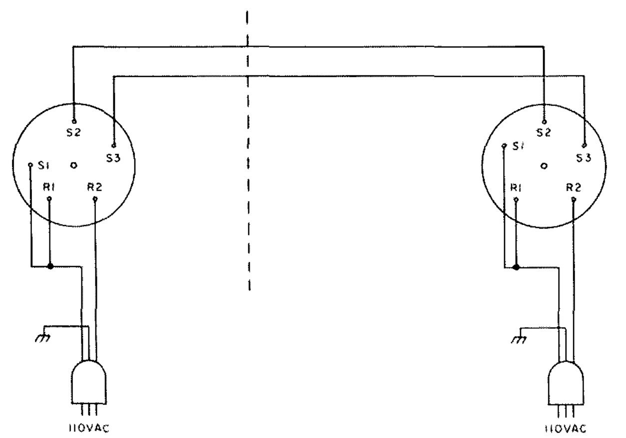

Fig. 3. Using household wiring to reduce to two the wires needed in a control cable for a synchronous transmitter-indicator.

matching capacitors can be rotated continuously, they present no problem for remote operating, but the bandswitching function requires a limit on rotation, and, further, the rotation must stop only when the switch is dead center on the desired set of contacts. To accomplish this requires the large switch seen in the center of Photo B plus a very important cam-driven microswitch concealed behind the mechanism, and gears in a 1:12 ratio.

Here is how it works: The large switch (it need only be a 5-pole, 5-position switch) is directly coupled to the Matchbox band selector switch. Both have 30-degree indexing. The common shaft is coupled into a 1:12 gear train which operates a cam that allows a microswitch to open only once in 30 degrees of rotation of the Matchbox bandswitch and coupled 5-pole switch. The small PM-field dc motor that drives the bandswitch takes a rotational direction determined by one of two relays in the small box directly behind it. But, once the motor is in motion, the microswitch is closed — and thus keeps the relay closed — until it is opened because the bandswitch is dead center on some set of bandswitch contacts.

The circuit diagram for this function is given in Fig. 1. A contact (in this case, a relay contact pair) is closed corresponding to the desired band to connect 24 V dc to the bank of 5 by 5 contacts. If some band other than the one to which the Matchbox happens to be set is desired, either RY-13 or RY-14 will be activated to connect the rotator motor for clockwise or counterclockwise rotation. Notice that two sets of contacts on each relay supply dc to the motor with opposite polarity. Once the 5-pole switch is off dead center of some switch position, the microswitch, being mechanically coupled to it, closes and holds the relay closed. Two conditions are required for rotation to stop: the selected bandswitch position has been reached and switch contacts are on dead center.

To accomplish complete remote control of the Matchbox and auxiliary grounding unit requires twelve functions: five Matchbox band positions; one auxiliary antenna in lieu of the Matchbox; tuning and matching capacitor rotation clockwise and counterclockwise; and antenna grounding and ungrounding. In addition, the position of the matching selsyn indicator must be transmitted to the operating position. To avoid the voltage drop in a long light-gauge wire, a 24 V dc supply and a source of 110 V ac were used at the Matchbox position, with the appropriate connections being made by a bank of 12 remotely activated relays. The simplest way, but most extravagant in its use of wire, would be to use an 18-wire control cable (including a ground return for the relays and five wires for the selsyn), but it is possible to reduce the number to four for controlling 12 relays and — provided 110 V ac is available at both Matchbox and operating position — two for the selsyn in-

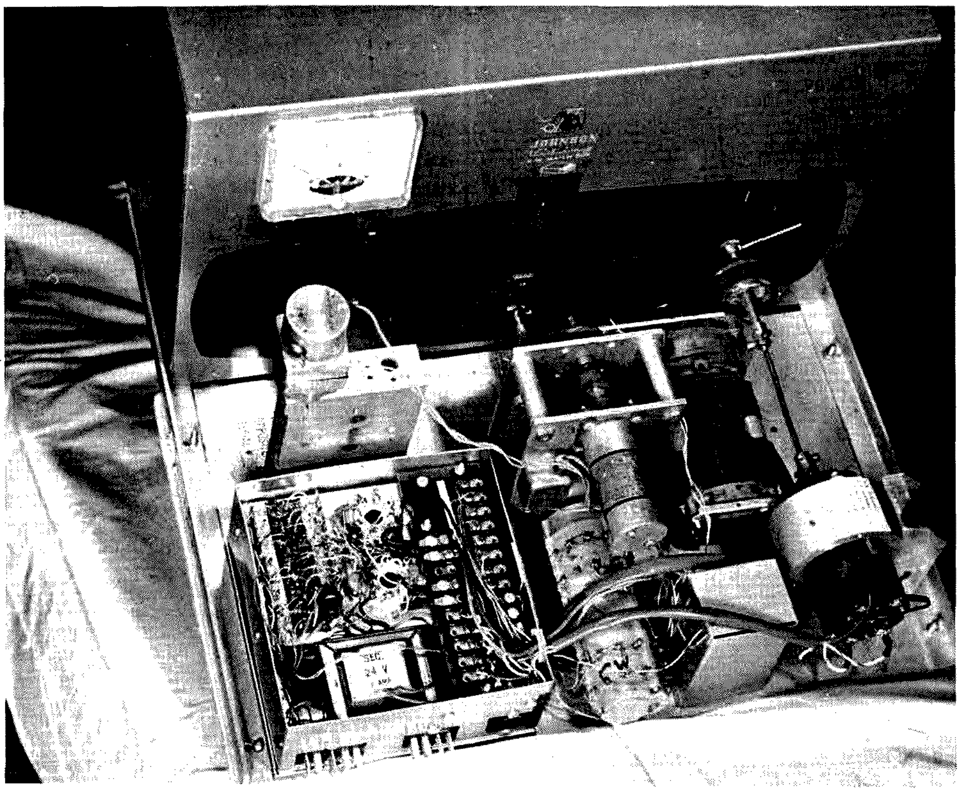

Photo B. Shelf for Matchbox motorizing units with control circuitry. Only the upper edge of the cam operating the microswitch is visible, near the center of the photo. Jones plugs in the small box connect the unit to the operating position control and the antenna grounding unit. By driving a matching capacitor with a timing-type belt, a shaft projection is available to drive the selsyn indicator.

dicator.

Fig. 2 shows how four wires can be used to operate 12 relays selectively. This circuit has been checked in breadboard, though not actually used in the pictured unit. The number of controllable relays has been doubled by using diodes such as 1N4004s so that each combination of wires one through four (e.g., 1-2; 1-3; 1-4; 2-3; 2-4; 3-4) can be used to select two relays. I plan to use a version of this for control of an EME setup.

Note, however, that this arrangement permits, in general, any one wire to be used for only one relay at a time. It works for circuits that do not require continuous relay energization. For example, if you wished to turn off the ac power for the 24 V dc supply and the selsyn from the operating location, it would be necessary to use an impulse-type relay because, while the ac circuit is activated, none of the other relays can be used; it's one relay at a time.

The operating console control unit shown in Photo C uses an eight-position push-button switch of the locking type, and some consideration had to be given to this configuration. Band selection, matching capacitor setting, and tuning capacitor setting must be done nonsimultaneously. This was ensured by using 2-pole, 3-position spring-return-to-center lever switches (Centralab # 1455s) for matching and tuning capacitor rotation. As shown in Fig. 2, operating either of these switches temporarily disconnects the push-button switch so that, temporarily, no power is applied to the respective relay and the center positions of the lever switches are in series. Note that a separate 24 V dc supply is in the control unit, though the 24 V dc needed for relay operation could have been obtained via the otherwise unneeded last two wires of an eight-wire cable. For relay operation, voltage drop would not be a consideration, as the current drawn is very light.

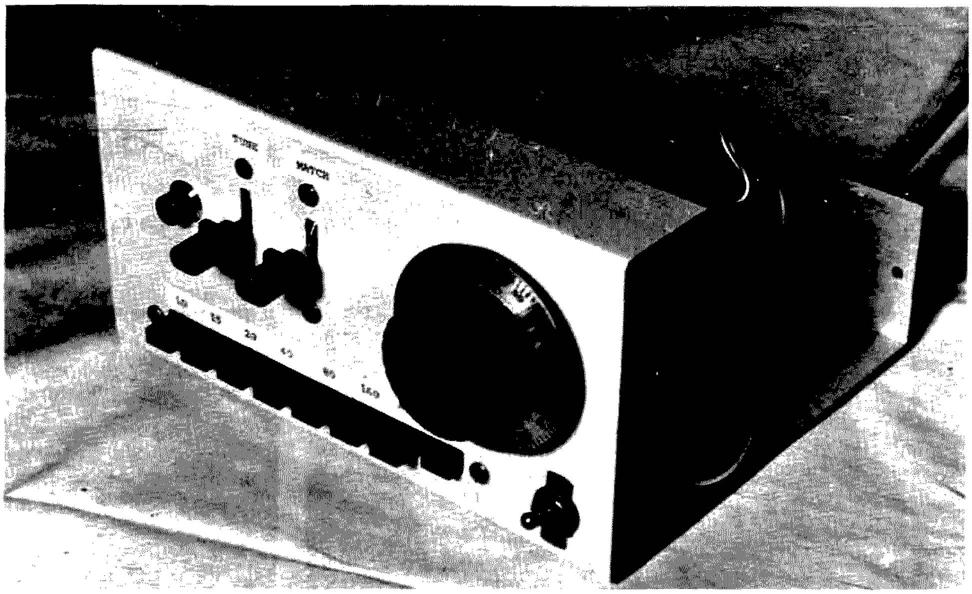

Photo C. Operating unit for remote control of antenna tuner, selection of antenna, and grounding of antenna for lightning protection. Dial is driven by a selsyn, which indicates the position of the matching capacitor. The unit is in a Ten-Tec MW-8 case.

As for the selsyn indicator, although conventionally five wires are used to connect the transmitter and indicator, all the textbooks show that the number can be reduced to four by using one common wire for rotor and field. But, if both indicator and transmitter are fed from the same household circuit, this circuit supplies two of the needed four wires and only two need be added in the control cable. It is possible that transmitter and indicator will be on opposite sides of a 220 V centertapped circuit, in which case rotor terminals will have to be reversed on one unit. Checking this idea out in breadboard verified that it worked, though it was not actually employed in the control unit pictured, which used a separate cable for the selsyn. See Fig. 3. With the common 8-wire cable, two selsyn indications (azimuth and elevation) and control for up to 12 relays (tuning, gain, etc.) for an EME setup could be obtained, given ac power at the antenna.

A few small points complete the story. I chose to use miniature 24 V dc relays where current requirements were light — e.g., closing other relay contacts — but I used heavier relays for operating motors. Because the relay supply had very poor regulation, it stood at 38 volts when in use for miniature relays but it was drawn down to 24 V dc for the larger relays. A regulated 24 V dc supply might be neater. I added series resistors to limit current in the miniature relays. Transient suppressors (G.E. type MOV-750) were used across the coils of the bigger relays and the 24 V dc motors.

That's about it. I've thought of more sophisticated systems, such as tone-controlled systems using SE567 tone decoder ICs or some shift register arrangement. I've also considered other applications for simple remote control — for example, tuning and gain-setting in a preamplifier mounted at the top of a tower, or changing polarization on a moonbounce or OSCAR antenna. As I've noted at several points, the circuit described is not the one used in the units pictured. This is because I built up the unit before figuring out how to minimize the number of connecting wires needed; however, all circuits diagrammed here have been checked out in breadboard form.

The collection of parts used and the construction are not what I'd use on a cost-plus government contract, but they are a good illustration of what is available at hamfest fleamarkets, to make an offbeat project feasible at trivial cost. ■

Diodes of the Dead

—eavesdrop on the great beyond

Bored with ho-hum projects? This ghost detector will spook you!

Si Dunn K5JRN
3607 Binkley
Dallas TX 75205

Recently, in a Dallas bookstore, some eerie pink words suddenly glowed at me from shelves of psychic phenomena books: *Break Through—Electronic Communication With the Dead May Be Possible!*

In seconds, I was mesmerized. I paid $2.25 plus tax and rushed home with my very own copy of Konstantin Raudive's "amazing study (more pink words on the cover) that reveals how tape recordings can suddenly become the medium for voices from the dead!"

You see, all you really need to eavesdrop on the conversations of the spirits, the good Latvian Dr. Raudive claims, is a tape recorder, supplemented—if you really want to get fancy—by a small handful of electronic parts obtainable from almost any Radio Shack or ham's junk box.

Here, at long last, was a psychic challenge I couldn't resist. I don't have much extrasensory perception (ESP), and I've never bent any keys or spoons with my brain. But I do have a well-used Sony tape recorder and 24 years experience with radio parts and soldering guns. And I found, in my closet junk box, the parts to duplicate most of the psychic listening devices diagrammed in Raudive's treatise, recently imported to the American paperback market from the darkest corners of mysterious Europe.

In *Break Through*, Raudive describes three extremely simple techniques that he claims will record the voices of the dead and their messages from "beyond." And he includes transcripts—translated from Latvian, German, Russian and Swedish—of ghostly conversations that allegedly showed up on blank tapes.

In method one, you connect a sensitive microphone to your tape recorder, insert a blank tape, politely ask some of the dead-and-gone to speak to you, and sit quietly in your living room or ham shack. After a few minutes, you play back the tape and listen carefully for any messages.

It might help, incidentally, to be fluent in several tongues, since, Dr. Raudive claims, the spirits "speak in an unmistakable rhythm and usually employ several languages in one sentence; the sentence construction obeys rules that differ radically from ordinary speech . . . (and) identification of the voices is . . . often a remarkably difficult task."

In method two, you tune an AM radio to a frequency clear of rock 'n roll and other earthly interferences and place the tape recorder's microphone near the radio's speaker. A clear channel in the vicinity of 200 meters (1500 kilohertz) is recommended, since this seems to be a medium wavelength favored by ghosts in Europe.

I elected, however, to go first to method three, the exotic "diode-recording" technique, because it requires a few radio parts, and the quality of the voices received from beyond, Dr. Raudive promises, is "nearest to those of ordinary human ones."

Curiously, the device I wired from Dr. Raudive's schematic looks exactly like a crystal radio, the kind I constructed from Cub Scout handbooks when I was a pre-Novice of 10. The only significant differences include the use of a diode instead of a cat's whisker and hunk of galena and an antenna limited to no more than about three inches, instead of the traditional 100 feet.

Still, I didn't let suspicion stand in the way of experimentation. In science, anything is possible. If the dead want to address the living over crystal radios, I'll sure as heck listen.

As I soldered the last connections and readied my tape recorder, I considered the immense possibilities. Suppose I eavesdropped on a bitter argument between Babe Ruth and Plato? What if I received, live and direct from Franz Schubert, the finish to his Unfinished Symphony?

I might even hear the confused cries of all the souls lost in the Bermuda Triangle, if the skip was right. I would be able to write a new book: *Diodes of the Dead! Eavesdropping On Eternity With A Crystal Radio!* And while it sold millions from coast to coast, the *National Enquirer* would print excerpts and an interview, and movie producers would come to me in parades of limousines.

Raudive recommends taping for no more than 10

or 15 minutes at a time because "examination of voices received may take several hours."

Turning on the recorder, I felt my excitement sharpen as I read that "children and people with a musically trained ear have least difficulty in following the voices; military-trained radio operators achieve a high degree of accuracy, and, for some unknown reason, specialists of internal medicine and Catholic priests also seem to be able to discern the voices with relative success."

I'm no doctor or priest, but I can play a harmonica by ear. I was a Navy radio operator, and now I hold an Extra Class ham license. And some of my friends might argue that, at age 34, I'm still a bit of the old child. With qualifications like these, I might not even need a crystal radio to hear Raudive's "voices."

The first 10-minute taping seemed to last forever. I carefully straightened the three-inch whip, tapped the tiny 1N914 diode and imagined all types of conversations flowing smoothly onto the tape. Ernest Hemingway might even offer from beyond to help me write, if I—in this world—would ghost his next novel.

Time at last to decode the first offerings from infinity, the dialogues of the dead, the jokes, the lessons, the exhortations from eternity. I rewound the tape and turned my ear expectantly to the first snaps, crackles, and pops emanating from the loudspeaker.

Nothing. Absolutely nothing but the electromagnetic void. Not even a static crash or whisper.

Desperately, I rechecked the wiring, rewound the tape, tried new tapes and methods one and two. But

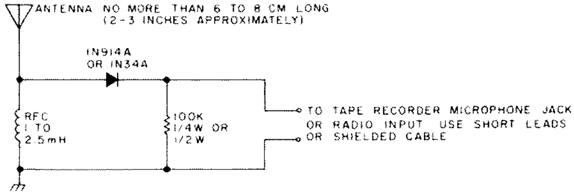

Fig. 1. Simple (too simple?) "voices of the dead" detector.

hour after hour, I heard nothing except the steady hissing of cheap cassettes and periodic moans and groans from the Sony's worn gears. At one point, the recorder stopped, as if seized suddenly by an unseen power. But it was only the batteries signaling that they were dead.

Sadly, I cast from my mind the outline for my best-seller. I threw Dr. Raudive's book into the pile to be sold soon at a used book store. But before I pitched the ghost detector into my junkbox, I hooked it to a 100-foot antenna and tried one more taping.

Voices poured forth in a babble: news, weather, sports, music. Just as I had suspected, I had not found the Bermuda Triangle, but I had reinvented the crystal radio.

The ghosts of the world probably laughed when I sat down at my typewriter and confessed: "Writer fails to communicate with dead despite explicit instructions." But ask me if I care. The *National Enquirer* probably will call me anyway, and I think I hear a movie producer's limousine pulling into my driveway right now . . . ■

Building an Economy Receiver

—junk box, here I come!

Broken radios and TVs are the mother lode for this project.

Tom McLaughlin WB4NEX
132 Bay Point Dr. NE
St. Petersburg FL 33704

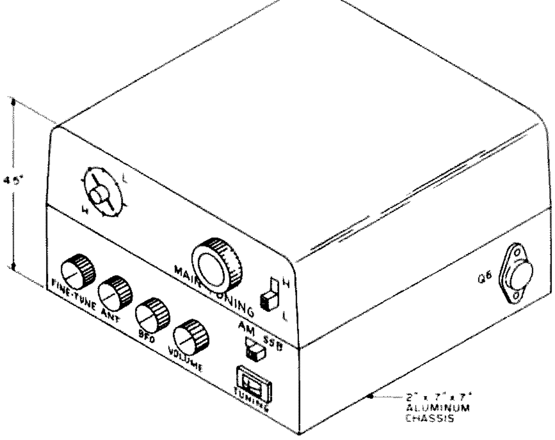

Fig. 1. Isometric view of the 6-15 MHz receiver.

Several years ago, I decided that I needed a good general-coverage "communications" receiver, one that had switchable bandwidth, CW filter, i-f and rf gain controls, etc. After looking for a while, I bought a used tube-type unit that would do everything except tune itself . . . ha.

I remember three or four occasions when I tuned the receiver to an AM broadcast station after warm-up, only to return a couple of hours later to find that the beast had moved itself up near the next station on the dial. This, of course, was an electronic and not a mechanical phenomenon and afflicted all bands. I worked on it for several months, but never did discover what was causing the drifting.

After having been properly educated in general-coverage receivers, I decided that I would look for something cheaper, something that offered less chance of getting burned. I wanted a fairly sensitive transistor unit, good selectivity, bfo for receiving SSB, and coverage of international shortwave and 20 and 40 meters; all this should be for less than $30 or so. I looked for quite a while. Obviously, I would have to build one myself.

Then along came the December, 1977, issue of *73*, and in it was the article "Build A Useful HF Receiver." Essentially, that was the basis of my receiver, although I have greatly expanded and mod-

ified the circuit. My design uses a 120 V ac supply, bfo, adjustable i-f gain, and tuning meter; it can be modified to suit any particular need. The tuning range is limited only by personal preference and coil-winding ability. Even without going to extremes, there is less than 100-cycle drift after a twenty-minute warm-up, and adjacent channel rejection is good. You may want to add more tuned circuits in the rf section to improve image rejection, but, for my purposes, the circuit as shown is more than adequate.

Most of the components can be salvaged from broken radio and TV sets; the whole setup is based on using readily available stuff in order to keep the cost down. For example, I used the power transformer from a 12" black and white transistor TV I found in someone's garbage, the main tuning capacitor from an AM radio, some transistors from the AFT board out of a color TV, and the tuning meter from a smashed tape recorder. I had some pieces of scrap vectorboard which I used to make the subassemblies. After they were all working, I installed them in the chassis.

Rf Section

An NPN rf transistor, Q1, is used to isolate the antenna from the mixer stage; the NE-2 bulb is added to absorb any static discharges from the antenna. An FM trap and a 2 MHz high-pass filter are used to eliminate spurious signals. I recommend using these additions because of the high gain provided by IC1. Several high-power AM and FM transmitters nearby caused problems without the filtering. C6 on the FM trap should be adjusted to null out any FM stations coming through after the receiver is working.

Rf chokes for the 2 MHz filter can very easily be obtained from a color TV; loads of them are used in the color circuitry. The coding is like resistors', except that two or three dots of color indicate the inductance as follows:

green + blue = 56 μH
red + black + brown = 200 μH
yellow + violet + white = 4.7 μH.

I-f and Audio Section

The mixer stage is a dual-gate diode-protected MOSFET, Q2, followed by a Miller 8901-B 455 kHz i-f transformer. Oscillator injection is provided by the vfo which supplies about ½ to 1 volt rms. Although the Miller 8901-B is supposed to be followed directly by the 8902-B amplifier module, I decided to add a differential IC i-f amp, IC1, between the two in order to improve the sen-

Parts List

C1	AM BCB variable capacitor, air dielectric; (a) antenna section, 10-365 pF; (b) oscillator section, 7-115 pF
C2, C4	variable capacitor, 5-50 pF (approximately) air dielectric
C3	variable capacitor, 1-7 pF (approximately), air dielectric; use one rotor and one stator plate, adjust spacing for desired tuning range.
C5, C6	ceramic trimmer capacitor, 8-50 pF, N750
C7, C9	ceramic trimmer capacitor, 5-25 pF, NPO
C8, C10	ceramic trimmer capacitor, 3-12 pF, NPO
IC1	CA3028A differential rf/i-f amp
IC2	MC1306P integrated audio amp/preamp
L_L	14 turns #22 enamel wire closewound on ½" diameter slug-tuned form, red slug; tap at 1¼ turns from ground end
L_H	6 turns #22 enamel wire closewound on ½" diameter slug-tuned form, red slug; tap at 1¼ turns from ground end
L_{OL}	31 turns #30 enamel wire closewound on ¼" diameter slug-tuned form, red slug
L_{OH}	14 turns #30 enamel wire closewound on ¼" diameter slug tuned form, red slug
L_B	AM BCB tube-type radio oscillator coil
Q1, Q3, Q4, Q5	2N4124 silicon NPN rf transistor (or equivalent); many types will work
Q2	40673 dual-gate MOSFET, gate protected
Q6	NPN power transistor, 10 Watts or more
D1, D2	1 Amp, 100 piv silicon rectifier diodes
ZD1, ZD2	8.2-volt, 1-Watt silicon zener diode
ZD3	10.0-volt, 1-Watt silicon zener diode
S1	three-pole, two-position slide switch
S2	DPDT slide switch
T1	power transformer, 120 V ac primary; 35 V ac, .5-Amp secondary, c-t. (can also use 24 V ac).
8901-B and 8902-B	i-f units, 455 kHz, made by J. W. Miller Co., Los Angeles.

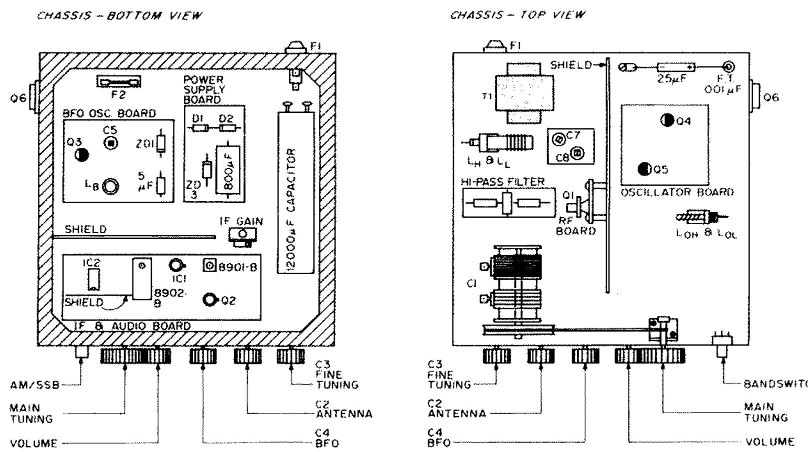

Fig. 2. Chassis and circuit board layout and component placement.

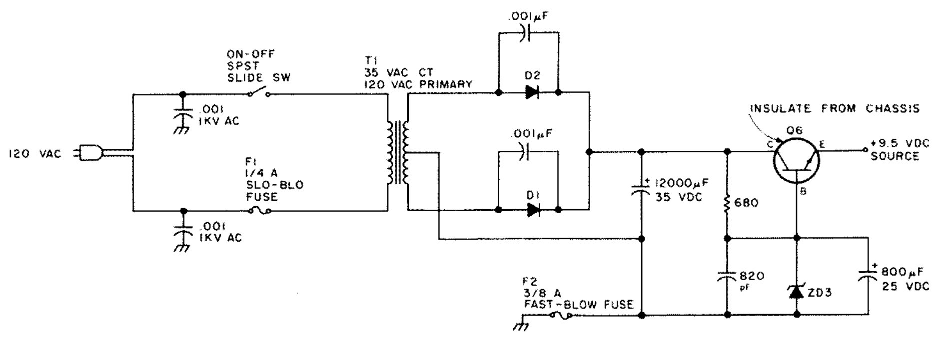

Fig. 3. +9.5-volt dc supply.

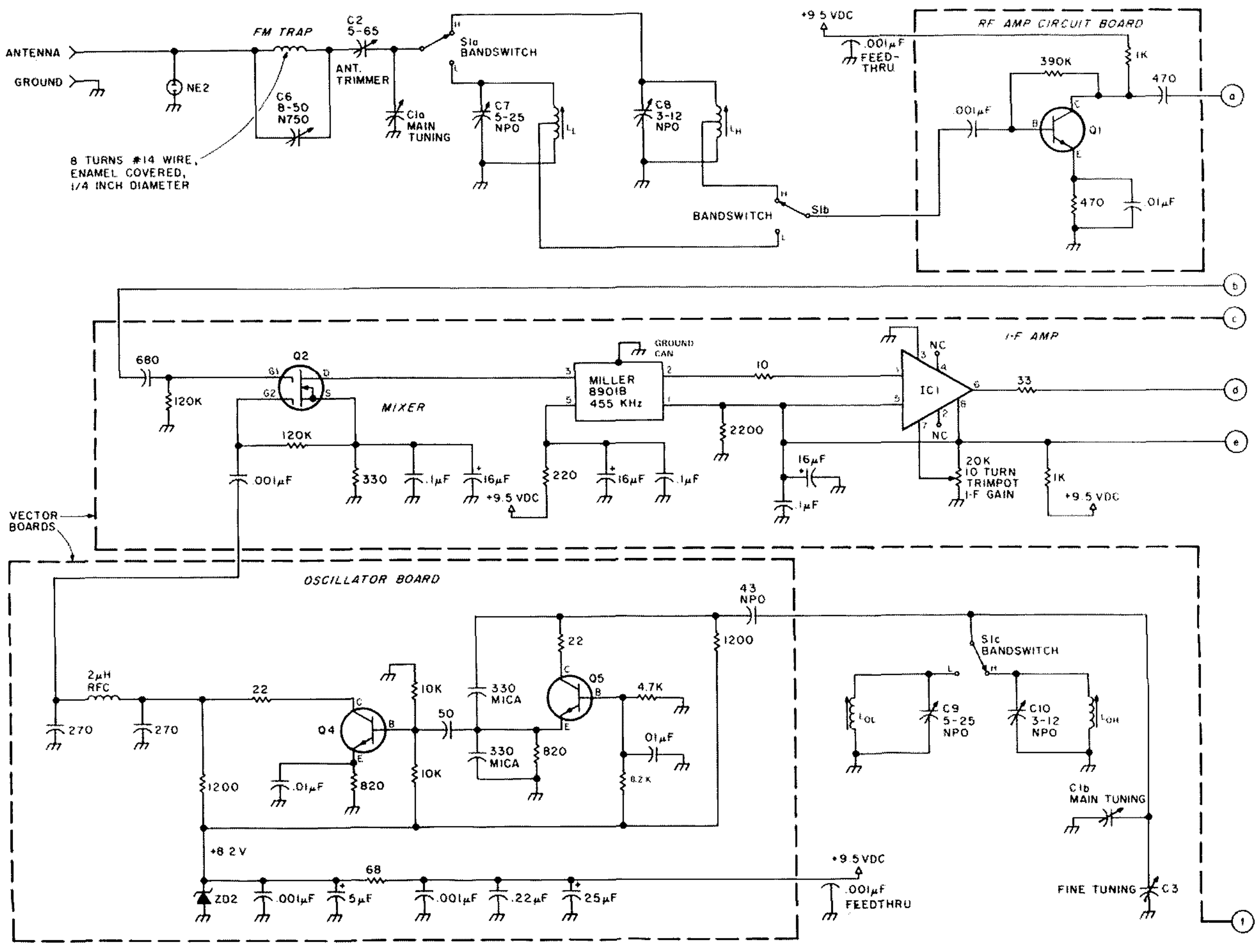

*Fig. 4. Circuit diagram for the 6-15 MHz receiver. *See text. L = 6-9 MHz; H = 9-15 MHz. Electrolytic capacitors are 25-volt units unless otherwise noted. All capacitor values are in picofarads. All resistors are ½-Watt, 10% tolerance.*

sitivity. This combination works very well, and you will find that the i-f gain is so high that you will not be able to use the unit with the gain control set all the way up. This is a tremendous advantage in a cheap receiver because you can compensate for the losses in the filters as well as for weak signal strength due to a lousy antenna.

Audio can be taken directly from pin 7 of the 8902-B module, or it can be taken from "pin 8" and run through a product detector for SSB and CW reception. Note that the module as supplied by Miller does not have pin 8 connected. You must remove the metal can and use a tiny piece of wire to connect pin 8 to the anode of the built-in AM detector. This is a very simple operation and does not require any particular skill. After you have replaced the metal shield, you are ready to install the module. If you choose not to use a tuning meter, you must ground pin 5 for dc return, or the module will not work.

Audio leads between the detectors, AM-SSB switch, S2, and the audio preamp/amp, IC2, should be kept as short as possible. The audio IC also has an extremely high gain, which is good for weak signals but creates a bad feedback problem if you don't use a small metal shield to separate the input components from the output circuitry.

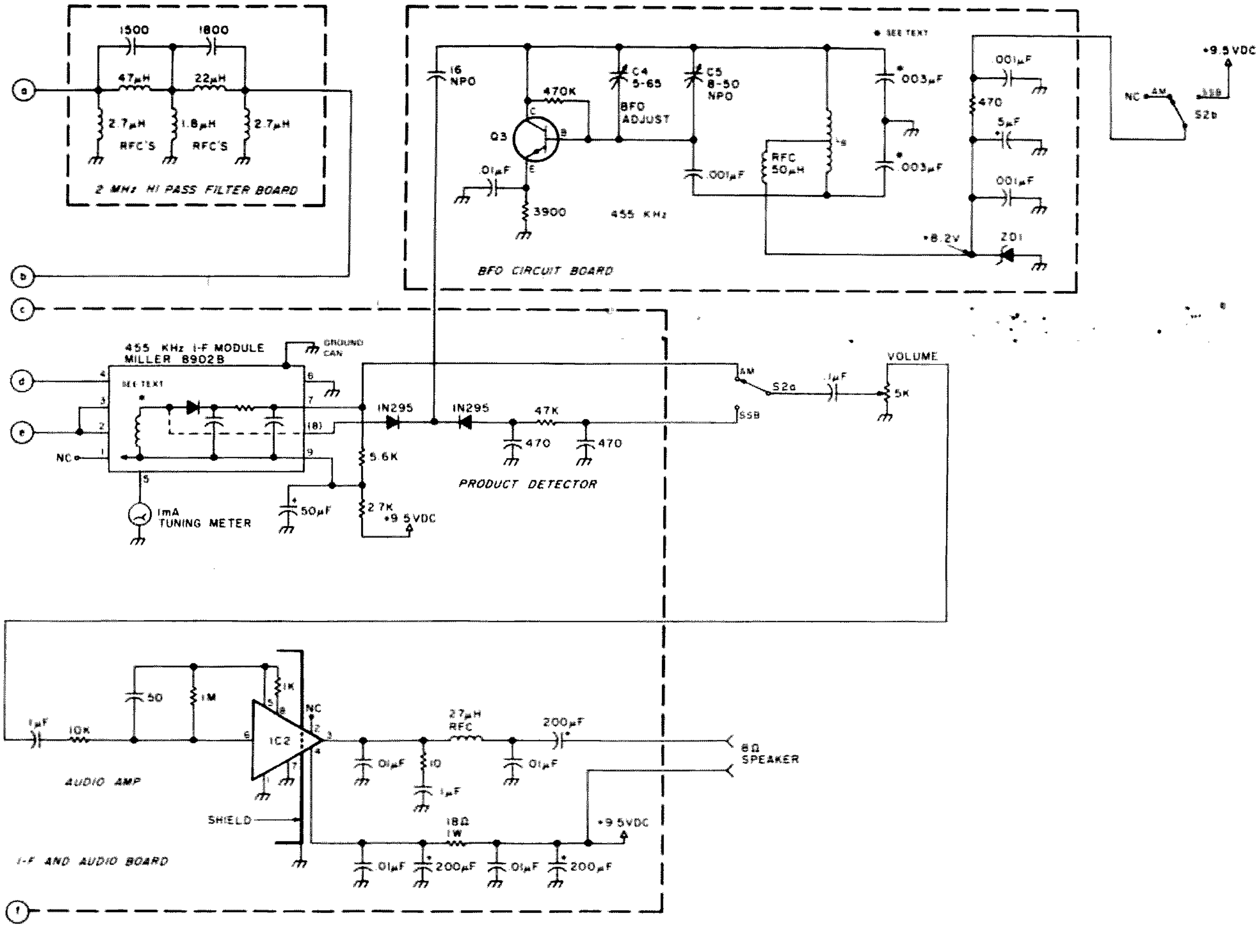
Vfo

The local oscillator is a two-stage setup consisting of a grounded-base oscillator, Q5, which is capacitor-coupled to a buffer amplifier, Q4. The output is fed to the mixer stage through a low-pass harmonic filter using two 270 pF capacitors and an rf choke. Rf chokes are not used to supply dc to the transistors; the circuit works very well without them and they may cause oscillation on two or more frequencies if they are used in this manner. Main tuning for the oscillator is provided by a parallel LC tank circuit using the oscillator section, $C1_b$, of a dual-ganged variable capacitor from a tube-type AM radio. The larger capacity section of this capacitor, $C1_a$, serves as tuning for the tuned rf tank circuit in the rf section.

It is important to use all the bypassing shown in the diagram to keep rf out of the power supply and to keep audio from modulating the vfo. I had a good bit of trouble with this, and I finally eliminated all of it with the .22 uF and 25 uF capacitors in parallel across the feedthrough capacitor supplying dc to the vfo board.

Bfo

Good stability for sideband reception is provided by an NPN transistor in a Colpitts configuration. The oscillator coil, L_b, is from a tube-type AM radio oscillator circuit, also. You will have to pad this coil to get it down to 455 kHz. Two .003 uF disc ceramic capacitors connected as shown worked with the coil I used, but these may have to be altered slightly with other coils. The location of the



tap is not too critical because an rf choke is used here for dc feed. Once you have the oscillator working near 455 kHz, the bfo adjustment capacitor, C4, should be set to its midpoint and C5 should be adjusted so the oscillator frequency is at the center of the i-f bandpass. Then you can adjust C4 at the front panel for upper or lower sideband.

Conclusion

Although this receiver is not a project for a beginner, it is really not complicated. A 15 MHz scope and a frequency counter were available to help get my unit working, but it is possible to finish up using only a high-Z voltmeter and rf probe, a general-purpose rf generator, and a grid-dip meter. You can use the receiver i-f and audio sections to tell what the other stages are doing, so it's a good idea to make those sections first. Be sure to use all the electrolytic capacitors shown so there is no audio feedback through the power supply. Note that the stages are separated from each other either by chassis placement or aluminum shields. ■

The ST-5 Plus

—improvements on a favorite TU

Two easy additions to the ST-5 double its performance.

Dick Sander K5QY
110 Starlight Drive
Plano TX 75074

The ST-5 is a popular radioteletype (RTTY) terminal unit that has been around for a long time. It has been offered as a kit, and many home brewers have built it from scratch. Unfortunately, I found that QRM on the HF bands easily wiped out the print on my ST-5. I made two modifications to improve its performance. First, I added a bandpass filter for 170 Hz shift (I included a bypass switch in case I wanted to receive 850 Hz shift). The 170 Hz shift input filter is directly from the ST-6 terminal unit. Next, I added an automatic threshold detector which is described in *Ham Radio*, November, 1973 ("Variable Shift RTTY Terminal Unit," by K. Sueker W3VF). The improved performance from these circuit modifications justifies the effort required to incorporate them.

To start, build the 170 Hz shift bandpass filter and automatic threshold detector on a printed circuit board. A printed circuit board for mounting and wiring the modifica-

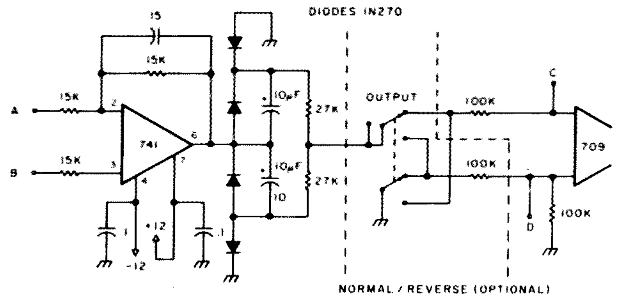

Fig. 3. Automatic threshold detector circuit, allowing copy of space keyed telemetry.

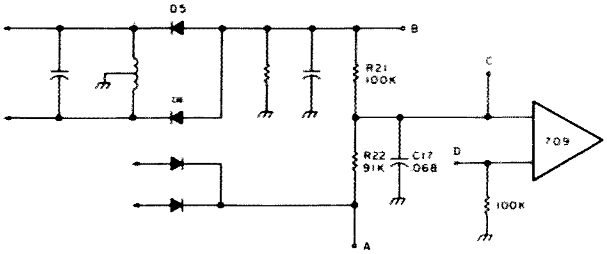

Fig. 4. Basic ST-5 discriminator.

tions is shown in Fig. 1. A breadboard is fine if a printed circuit board is not desired. A schematic for the bandpass filter is shown in Fig. 2. The 22 mH toroids are 88 mH toroids with the parallel windings in proper phase (sleeved ends together).

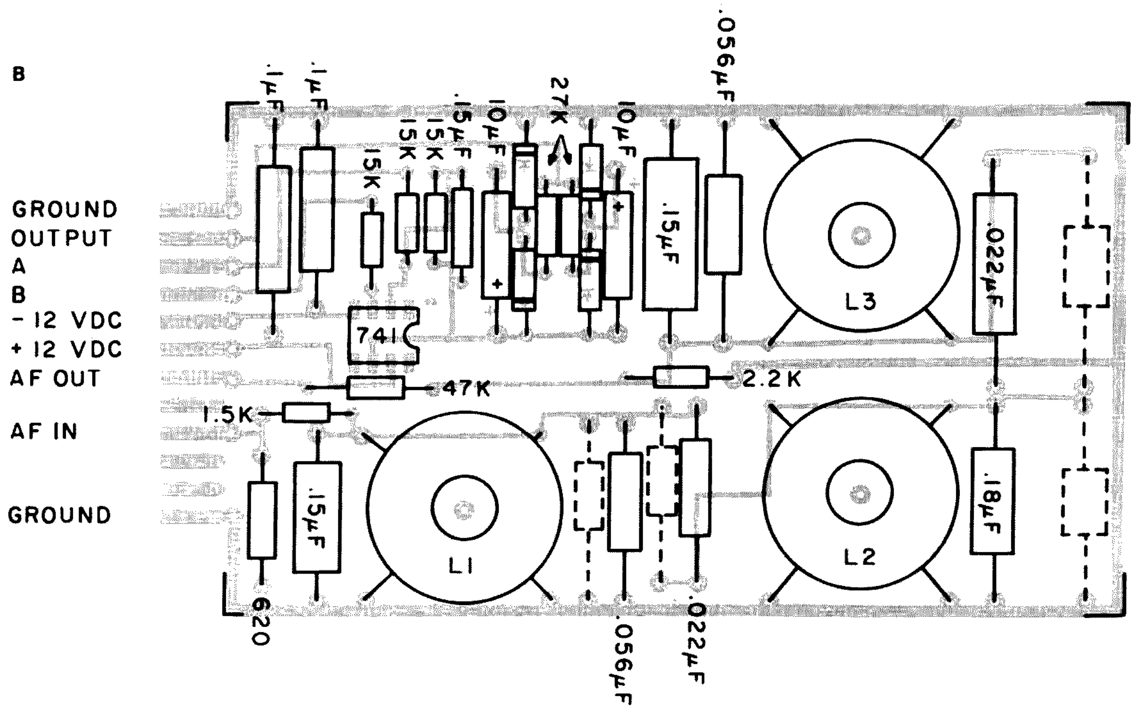
After the detector-filter board is complete, tune the 170 Hz shift bandpass filter, and then wire the automatic threshold circuit into the ST-5. Tuning the 170 Hz shift input filter is not critical. However, addition of a small capacitance may be required to correct the likely high-frequency response of the filter. On the printed circuit board, extra holes are used for trimmer capacitors. Tune each toroid to 2195 kHz as follows:

1. Tune the first 22 mH toroid, L1, to 2195 kHz with the 0.15 uF, 0.056 uF, and 0.022 uF coupling capacitors shorted to ground.
2. Tune the second 22 mH toroid, L2, to 2195 kHz with the 0.18 uF and second 0.022 uF coupling capacitors shorted to ground.
3. Tune the third 22 mH toroid to 2195 kHz with the 0.056 uF and 0.15 uF capacitors.
4. Reinstall both 0.022 uF coupling capacitors from ground back to the proper toroid.
5. Wire the 170 Hz shift bandpass filter to the ST-5 input.

To wire the automatic threshold detector into the ST-5, make the following changes and see Fig. 4:

1. Remove the 100k and 91k resistors and 0.068 uF capacitor from existing circuit.
2. Reverse the 1N270 diodes, D5 and D6.
3. Wire the automatic threshold detector into the ST-5 at points A, B, C, and D as shown in the schematic diagrams.
4. Wire the 741 operational amplifier to +12 and −12 V dc.
5. If desired, a NORMAL/REVERSE switch may be installed into the ST-5. See Fig. 3.

There are no adjustments required for the automatic threshold circuit. After both circuits are wired into the ST-5, you will find tuning a RTTY station is very easy and QRM will not interfere with the pictures you're trying to copy. ■



Build a $10 Digital Thermometer

—hundreds of uses

Gary McClellan
2500 Harbor Blvd.
Fulleton CA 92634

You may not realize it, but a digital thermometer may be very useful around the home, lab, and shack. Besides using one to determine how hot or cold it is outside, and checking out cheap thermometers, you can do far more! For example, around the home, you can use a thermometer to check for heat loss (energy waste) in furnace and hot water heater insulation, check refrigerators and freezers for proper operation, and adjust the temperature of your hot water supply. Then, in the lab, you can check your home-brew circuitry for hot spots that cut component life, look at temperature rise in electrolytics and power transformers, and then adjust other thermostats or temperature controllers for proper operation. In the shack, use one to check crystal ovens, check rf power transistors to see if more heat sinking is needed, and so on. Or, how about using a thermometer to monitor the heat sink temperature on your transmitter finals to prevent damage. This could sure cut down on those long QSOs! If you can't think up more or better ideas for a digital thermometer by now, you disappoint me! Let's see what you can do.

The digital thermometer circuit presented here is a low-cost unit, costing around $10 to build, yet it works well and will measure temperature from 0°C to 100°C with an accuracy of ±1°C. This unit is really a companion to our model 101 DVM kit or MC-1405 DVM.* It puts out a dc voltage which is equal to the temperature in degrees centigrade. You may also use a 0-to-1-volt analog meter, or any digital multimeter if you wish. Calibration is fairly easy, too, and I have found a way to make it easier! There will be more on this, later.

The temperature limits of a thermometer are important, too. This one measures from 0°C to 100°C, or from the freezing point of water at sea level to the boiling point of water under the same conditions. You can measure temperatures slightly outside of this range at reduced accuracy. For example, I have a thermometer that is in calibration at 0°C. I dunked the probe into a −55°C temperature bath and the thermometer was 5 degrees off. I checked calibration at +125°C and calibration was off only 2 degrees! So that shows how far you can go. The sensor in this unit is a silicon diode, and the two temperature extremes are the maximum ratings of the diodes.

Here's an assembled digital thermometer. It gives good accuracy at a very low cost.

*"DVMs Get Simpler and Simpler," Gary McClellan, *73 Magazine*, February, 1977.

Fig. 1 shows a simplified schematic of the thermometer module. This unit is based on the fact that silicon diodes have the property of the junction voltage changing linearly with temperature. Actually, most solid-state devices have some sort of voltage change with temperature. In this case, a cheap 1N4148 diode will change 2.2 mV per degree centigrade. So all we have to do is bias the diode in the conducting mode, then amplify the signal and adjust it for a reading in degrees centigrade. A precision, dual-tracking power supply of ±12 volts completes this circuit, and assures excellent long-term accuracy.

You should be aware that there are other methods of sensing temperature, but none offer the combination of accuracy *and* low cost. For example, there is the thermistor sensor. Lots of thermometer construction articles using thermistors have appeared in other magazines, but thermistors

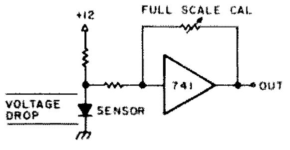


Fig. 1. Simplified schematic diagram of thermometer.

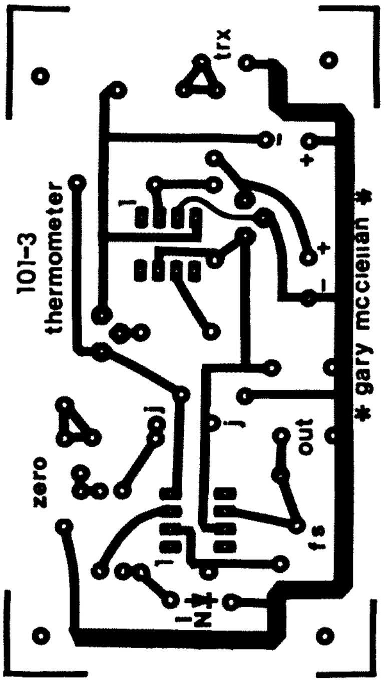

Fig. 2. PC board layout.

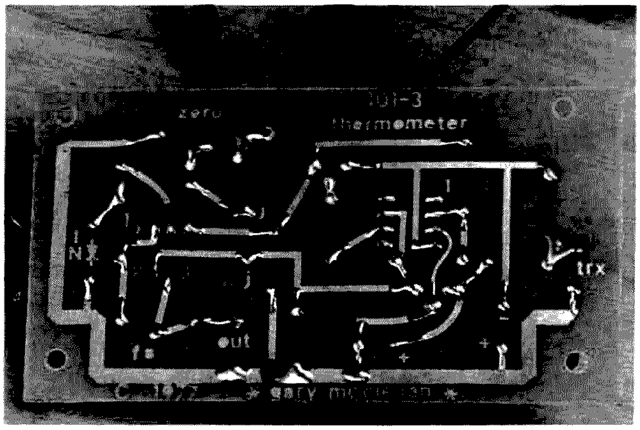

Underside of the thermometer circuit board.

in the proper resistance ranges are usually hard to get and must be special ordered. Also, if you step on it or destroy it in some way, you must order another one and wait, wait, wait by the mailbox. Then you must recalibrate your box for the new thermistor. With my unit, if you break the diode, a new one costs only pennies and is readily available. You still have to calibrate your module, but a new sensor is easy to get. That's a big reason why I use diodes. I have accidentally broken sensors of both types, and I would much rather break a diode any day! Another type of sensor is the thermocouple. This is the original electronic sensor, and I'm sure most old-time people in the temperature measurement field will doff their hats at the mention of the word. This is just two pieces of wire (made of different materials) clipped together at one end. Thermocouples have the advantage of being able to measure a wide range of temperatures, and also they are interchangeable without recalibration on a thermometer. One of the most popular thermocouples, the type K, or copper-constantin wire, has a temperature range of −270° to over +600°C!

Quite a difference from that diode. But thermocouple thermometers are much harder to build, and thus cost more. There are a good many $300 boxes out there on the market. So, by now, you can see why I am using that diode as a sensor, and perhaps appreciate how it relates to the other sensors.

Construction of this project is easy. A full-size printed circuit layout is given to aid you (Fig. 2). Simply duplicate the board, drill it, and stuff it with the parts, an easy two-evening project. The complete schematic diagram is shown in Fig. 3.

After you have the board, you will want to scrounge the parts. Good sources for IC3 might include *73* advertisers. Another place is Active Electronics, PO Box 1035, Framingham MA 01701. They have had them for 29 cents each plus postage. It's the same deal with the op amps. They do have a $10 minimum order, but their prices on the 78L12 regulator is tops as I write this, so you may have to combine several projects' worth of parts to place an order. One very important thing: Do not use re-tested junk parts in this project. If you do, it probably won't stay in calibration. A word to the wise is sufficient. The next problem parts are the pots. I used surplus Beckman Instruments type 89PR10K for the 10k pot, and a Beckman type 89PR100K pot for the 100k unit. These are available from Beckman distribu-

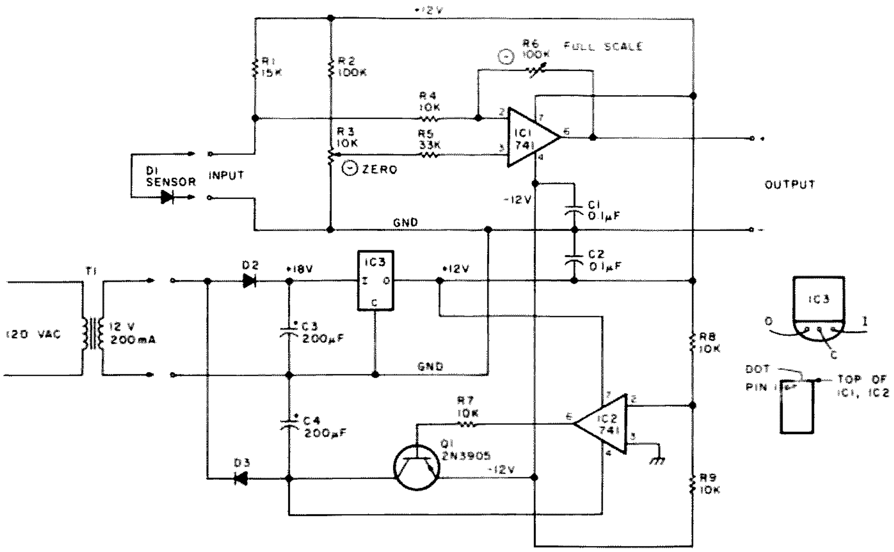

Fig. 3. Schematic diagram of Model 101-3 digital thermometer.

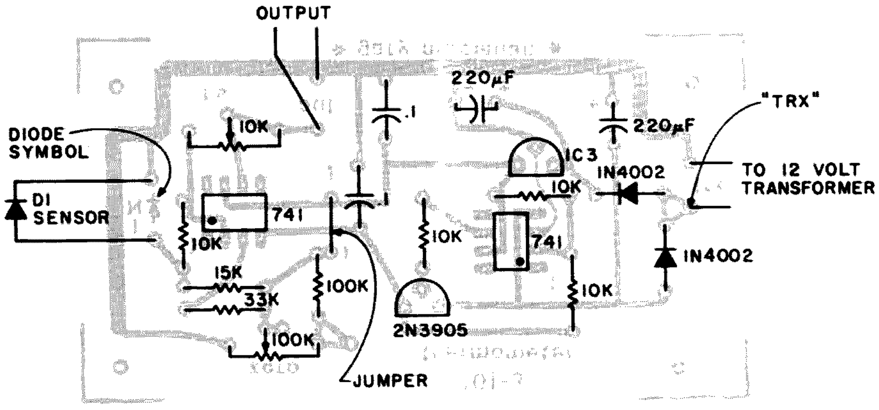

Fig. 4. Component layout. Don't forget the jumper!

tors, such as Fisher-Brownell here on the West Coast and others. They cost about $1 each. If you can't find these pots, drop me a line. They are the 3/4-inch long rectangular, cermet units. Others will work, however.

The next step is obvious—build it! Just follow the Fig. 4 illustration and you will have no problems. After you are done, attach leads for the output, and connect the transformer. Then do the usual checks for wiring errors, etc.

The sensor deserves special comment. It is just a diode on the end of a 2-foot piece of wire. For best results, get Teflon® hookup wire. Number 24 stranded wire with Teflon will do fine. You could use a short length of speaker wire here, but this type of wire has insulation that softens considerably at 100°C. Try not to use it—especially if you plan to do a lot of 100° measuring! Fig. 5 shows the details. There are several ways to construct the probe. A good universal probe can be made as shown by first slipping a 3-inch piece of Teflon tubing over the wires as a handle, then forming the diode leads and attaching them to the other leads. It might help to punch several holes along the edge of the tubing for the next step. Epoxy doesn't stick too well to Teflon. Finish up the general purpose probe by dipping it into epoxy. Cover up the end of the tube and let the epoxy set. You can make a special probe, such as for attaching to heat sinks, etc., by obtaining a small crimp-on lug from an auto parts store. Epoxy the diode and wires inside the lug (insulate so they don't touch it) and you are all set.

After you finish with the wiring, plug in the transformer, and check the voltages on pins 7 and 4 of IC1. They should be plus and minus 12 volts respectively. Then measure the voltage across the input terminals. It should be around 0.5 to 0.6 volts. If not, reverse the input leads and recheck. If it is still not right, the sensor is bad.

Finish up with the calibration. First, prepare a dish of cracked ice, and then return it to the freezer until needed. Also, heat up a pan of water until it boils. Turn your attention to the module and put your voltmeter between ground and pin 3 on IC1. Adjust R3 (zero) for a reading of 0.510 volts. The sensor should be at room temperature right now. Then connect your voltmeter to the output leads and adjust R6 (FS) for about 25°C or whatever the current room temperature is. These adjustments will put your thermometer in the ball park. Get out the cracked ice and place it within easy reach of the boiling water. Plunge the sensor into the ice and adjust R3 (zero) for 000 on the 1- or 2-volt scale of your meter. Then transfer the sensor to the boiling water, wait a minute until the meter settles down, and adjust R6 (FS) for a reading of 1000. Return the sensor to the ice, wait a minute for things to cool down, and readjust R3. Repeat with the boiling water and R6. For best results, do these steps at least 5 times. If

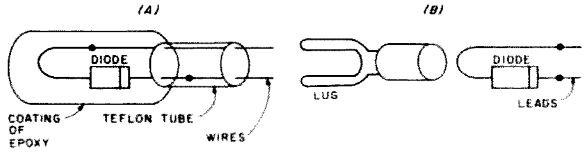

Fig. 5. Thermometer probe construction details: (a) general purpose, (b) mountable probe for heat sinks, etc.

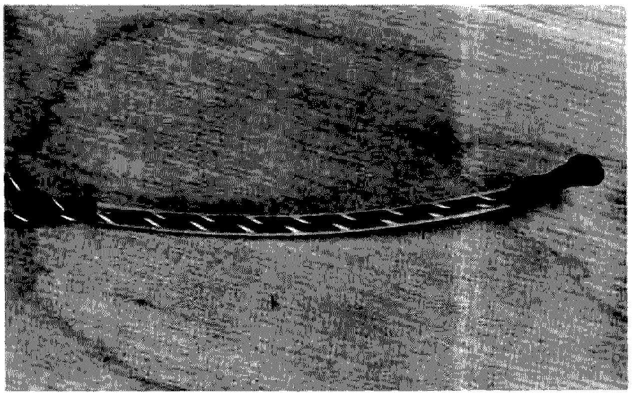
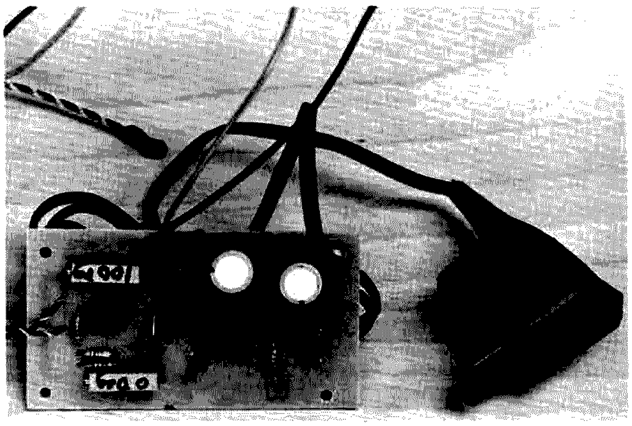


This is a shot of the universal sensor probe. Try not to use as much epoxy over the diode as I did; the excess epoxy slows down response time.



Top view of the completed thermometer option. All that's needed is a digital voltmeter for operation.

you do, you will be within a few degrees of the correct temperature. For even better accuracy, use a well-calibrated commercial digital thermometer to compare with your thermometer.

Using your new thermometer is a snap! Simply touch the probe to the surface you want to measure. Then wait a minute or so for the temperature reading on your voltmeter to stabilize (always use the 1- or 2-volt scale) and note the reading. Your meter will show, if it is digital, degrees and tenths of degrees. So 390 on the meter is 39.0°C, 1001 is 100.1°C, and so on.

Now that you have a thermometer, why not think up some more uses for it and let all of us know about it! How about solar heating applications? More ham radio applications, etc.?■

Parts List

C1, C2	0.1 uF, disc capacitor
C3, C4	200-470 uF, 25 V electrolytic capacitor
D1	1N4148 diode
D2, D3	1N4002-1N4007 diodes (1 Amp)
IC1, IC2	LM741CN Op Amp (mini-DIP)
IC3	Fairchild-type 78L12, 100 mA voltage regulator
Q1	2N3905 PNP silicon transistor
R1	15k
R2	100k
R3	10k, 10-turn pot
R4, 7-9	10k
R5	33k
R6	100k, 10-turn pot
T1	117/12 V ac, 200 mA wall plug transformer
Misc:	Model 101-3 PC board, 16 Molex® pins, hookup wire

DX

from page 6

kHz at 1500Z is a good place to snag a few new ones. As with any net, listen until you understand the correct call-in procedure.

Congratulations to the new officers of the Iowa DX Association. Doug Byal WØSML is the president. Gary Letchford KØLUZ is VP, and Fred Benson KØAT is the secretary/treasurer. If you would like to join up, drop Fred a note in Cedar Rapids.

CO2FA notes that it takes four IRCs and 1¢ from his own pocket to purchase one air mail stamp. This is another case where one Yankee dollar is better for all concerned.

Often stations are heard signing /4U, and many have been wondering what exactly they count for in regard to DXCC. You can get DXCC credit for their actual location, and it helps if the QSL shows the exact QTH. This is straightforward, but sometimes confusing.

If you work any stations signing EI8H/, it will be a pirate. EI8H is for real, but someone has been using his call portable from such locations as PYØ, GU, HV1, etc. All are phonies.

WA3HUP has been reported as having some VU2ANI/VU7ANI logs on hand. If you need a card, you might drop Mary Ann a line to see if she can help out. She has long been one of the top QSL managers around.

Jerry McManus, who operated 4W1GM back in 1975, says he received verbal permission to operate, but since that official was later assassinated, he is somewhat reluctant to try. Jerry feels that any present 4W1 operation would be open to question. Work 'em first, etc.

K5YY became seriously ill upon his return from Africa, and the QSL chore was delayed for a while. Remember this, if your card seems late in arriving.

During his VS6HK operation last September, W6MJE took a side trip and operated CR9AJ. These QSLs will be sent out automatically via the bureaus, so don't bother QSLing CR9AJ for contacts on September 20/21.

Tuvalu has been assigned the prefix block T2A to T2Z. VR8O will now be signing T2O.

If you still need a QSL for the last operation from Heard Island, VKØHM, in 1970, try W7PHO. Bill has all the logs.

4LØ calls are Russians operating north of the Arctic Circle.

Although the U.S. *Callbook* shows only about 20,000 JAs licensed, JARL figures show the total to be 359,005 as of last August. The discrepancy stems from the fact that, due to language problems, the *Callbook* must depend on individual Japanese amateurs to advise them of their QTHs.

At the IARU Region III meeting in Bangkok last October, VS6AW noted that there were some 350 Hong Kong Chinese waiting to take the written portion of the amateur exam in December and that many more waiting for the next opportunity. Look for an influx of VS6s if everybody passes.

Speaking of the IARU Region III meeting, Fred Laun HS1ASD reports that there was a good turnout and lots of support for WARC '79.

The People's Republic of China responded to an invitation to attend the Region III conference by stating that since amateur radio activities had not *yet* been restored, it would be difficult to send an observer. Read into that anything you wish. If Clipperton, Iraq, Somalia, and Bouvet, then why not China?

3F75 prefixes are being used by Panama stations through February 3, 1979, to celebrate the 75th anniversary of Panama's independence. HP1KC will sign 3F75KC, etc.

Jacky F6BBJ apparently ran into difficulties with his planned Abu Ail operation. But those in the know stay alert. You never can tell what the day will bring.

Speaking of staying alert, the Italians are hinting at big doings from ZA (Albania).

Apparently, lack of interest and some confusion over the new callsigns has caused the KS6 QSL bureau to fold. Local advice out of Samoa suggests you QSL direct wherever possible.

Several PY stations were planning a PYØ swing during December or early January, covering Fernando de Noronha, Rocas Atoll, St. Peter, and St. Paul. Rocas Atoll has a new autonomous administration and the PYs feel it should count as a new one. No doubt there will be more on this later.

4LØKR was a special call to mark the 350th anniversary of the city of Krasnoyarsk in central Siberia. QSL to UKØAAB.

Speaking of Siberia, UK9AAN has up a five over five on ten meters spaced ten meters apart on top of a 14 story building. UK9AAN is at the Ural Polytechnic Institute in Chelyabinsk.

The great New England Schrodfest attracted Father Moran 9N1MM along with PY1RO, to tell about the recent St. Peter and St. Paul operation, and well-known DXer Don Riebbhoff.

If you worked FH8DK and he said to QSL via WA6BJS, forget it. Herb says he is the QSL manager for no one.

Although K5OVC, subject of our December DX Profile, was recently mentioned in a Personal Communications Foundation advertisement as having TVI problems, Lenny wants it known that everything is serene in Arkansas. The TVI problems were in New York when Lenny was W2OVC, and are now just a bad memory.

Many Pacific Ocean stations can be found on one or more of the nightly Pacific DX nets. P29JS invites stateside check-ins on 14222 from 0600Z. ZL1ADI holds forth on 14285 from 0530Z, and N2KW MCs the East-West Net on 14247 from 0430Z.

The new address for any future DX activity by VE3FXT is George Collins, Box 89, Lynden, Ontario LØR 1TØ, Canada. Arrangements have been made to have the mail collected from the box daily and the QSLs processed. George also notes that his February, 1978, activity from H5 (Bophuthatswana) was actually from Thaba Nchu in the southern province of that country. Many feel that the present DXCC criteria will make this a separate country from the north province.

The sunspot count countinues to climb beyond expectations. Many of those predicting an early doom for cycle 21 now say that it may prove to be one of the best ever. The real truth probably lies somewhere in between.

Larry LeKashman W9IOP, one of the founders of the CQ WW DX test, passed away recently, and the 1978 CQ WW test was dedicated to his memory.

The FT-101 that was shipped to YI1BGD by the Northern California DX Foundation is still being held by the SWISSAIR office there in Baghdad, with delivery efforts going to no avail. The airline wants $250.00 to ship it back,

CB to 10

—part XVI: a CW conversion

Change one crystal and work the world legally with 5 Watts.

With three years of operating 10 meter QRP using converted CB rigs behind me, I decided to look for ways to monitor band openings by taking advantage of the CW beacons around the world. At the same time, 10 meter CW sounded like a lot of fun. In order to accomplish these goals, I established the following criteria which I wanted incorporated into the finished product:

1. 10 meter beacon coverage;
2. CW transmit capabilities on both General and

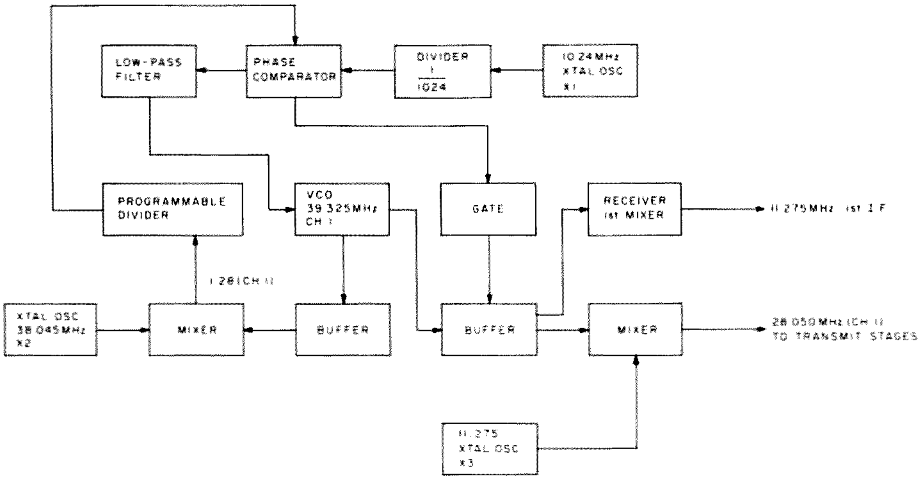

Fig. 1. Block diagram of phase-locked loop circuitry in the Sharp CB-800A with frequencies indicated for 10 meter coverage.

Ch.	fo	fvco	÷n

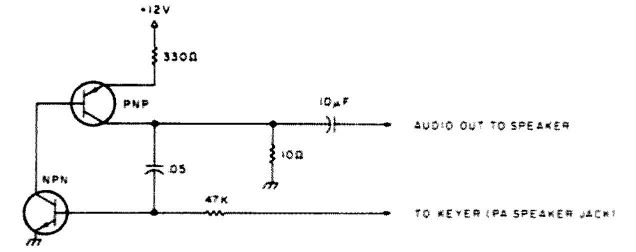

Fig. 2. Sidetone oscillator circuit. Transistors can be any general-purpose audio types. The .05 uF capacitors may be changed to vary the tone.

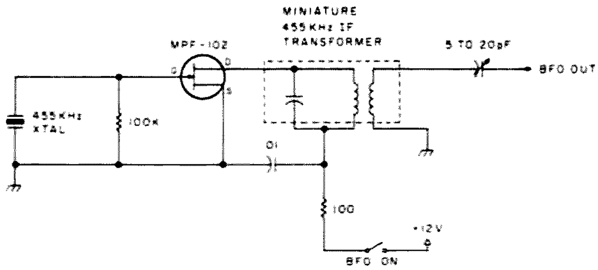

Fig. 3. 455-kHz bfo circuit.

Novice frequencies;
3. QRP operation of 5 Watts or less; and
4. price range between $30 and $40.

After researching the market, I decided on the Sharp model CB-800A phase-locked loop AM transceiver, which was readily available in my area for a price well under forty dollars.

An examination of the service manual for the CB-800A indicated that I would be able to meet the above goals. The frequency coverage I decided upon is shown in Table 1 with the beacon frequencies and identifications listed below:

Ch. 9	28.150	WA1EOB
Ch. 10	28.160	PY1CK
Ch. 11	28.170	ZL2MHF
Ch. 12	28.190	3B8MS
Ch. 12	28.190	DLØIGI
Ch. 13	28.200	JA1GY
Ch. 14	28.210	N4RD
Ch. 15	28.220	GB3CX

The first step in the conversion is to review the PLL frequency generation as shown in Fig. 1. As can be seen, the vco stage is the heart of the unit. In the original circuit, a vco frequency of 38.240 MHz was mixed with a received frequency of 26.965 MHz (Ch. 1) to produce a first i-f frequency of 11.275 MHz.

In the transmit mode, the vco output was mixed with an 11.275-MHz crystal oscillator to produce the 26.965-MHz transmit signal for channel 1. From this information, we can generate a formula to determine the vco frequency to enable us to transmit and receive on 28.050 MHz for channel 1. Thus, $f_o + f_{i\text{-}f} = f_{vco}$, where f_o is the operating frequency and $f_{i\text{-}f}$ is the frequency of the first i-f. With an operating frequency of 28.050 MHz for channel 1, the vco frequency must be changed to 39.325 MHz. It is very important, when converting a PLL circuit, that the original division factor for the programmable divider be maintained. As can be seen in Fig. 1, the division factor for channel 1 is 1.28. By changing the frequency of the original 36.960 MHz crystal (X2), we can do this. Thus, $f_{vco} - 1.28 =$ 38.045 MHz, the new frequency of X2.

With the new 38.045 MHz installed, perform the following steps to align the PLL circuit:

1. Place the channel selector switch to channel 12.
2. Connect an rf voltmeter to C220 at the output of Q206, and tune T203 for maximum output at 38.045 MHz.
3. Disconnect the rf voltmeter.
4. Connect a frequency counter to TP206 at the output of the vco transistor, Q203, and tune T201 for 39.465 MHz.
5. Disconnect the frequency counter.
6. Connect an rf voltmeter to TP2 at the output of the vco buffer transistor, Q202, and tune T202 for maximum output at 39.465 MHz.
7. Disconnect the rf voltmeter.
8. Connect a frequency counter to pin 15 of IC203, and verify the existence of a 1.42-MHz input signal.
9. Disconnect the frequency counter.
10. Measure the dc voltage at TP206. A voltage of approximately +2.7 indicates that the PLL circuit is locked. Zero indicates an unlocked condition.

This completes the PLL alignment. The receiver circuit alignment is as follows:

1. With the channel selector switch in the channel 12 position, connect a 28.190-MHz signal to the antenna jack.
2. Tune transformers T1, T2, and T3 for maximum S-meter indication.
3. Disconnect the signal generator.

This completes the receiver alignment. The transmitter alignment is as follows:

1. Connect a 50-Ohm dummy load to the antenna jack.
2. With the channel selector switch still in the channel 12 position, key the transmitter and tune T302, T303, T304, L302, and L303 for maximum rf output.
3. With a frequency counter, verify that the transmitted frequency is 28.190 MHz.

This completes the transmitter alignment, and you are now ready to make the necessary modifications for CW operation. The first step is to establish a method for keying the transmitter. This is accomplished by disconnecting the wiring to the existing PA switch located on the squelch control. Use this switch to energize the T-R relay in the CW mode. Unground the emitter resistor of Q303, the first rf amplifier in the transmitter, and connect it to the now-unused PA speaker jack. This will be the keyer connection. One word of caution: The ground side of the PA speaker jack is connected to the chassis. Before making any connections to the jack, break the connection to the chassis and connect the ground side of the jack to the circuit board ground.

The sidetone oscillator circuit shown in Fig. 2 and the receiver bfo circuit shown in Fig. 3 work very well and are small enough to fit inside the rig with no external mounting necessary. The output of the bfo circuit is high enough so that no direct connection to the receiver i-f is necessary. I simply positioned the wire from the bfo output across IC1, the receiver i-f circuit. Remember that in both the sidetone oscillator and the bfo circuit, ground connections are to the circuit board ground and not to the chassis ground.

Whether you decide to use the rig as a beacon monitor or a QRP rig, you will find it very enjoyable. I have had many contacts with it and all with good reports of CW quality.

So trade in your mic for a key and have fun on 10 meter CW! ■

Try a little KISS

—you'll love it

Reliable portable power has been right under your nose.

J. Tom Badgett K8AO
400 Albemarle St.
Bluefield WV 24701

Almost as familiar in hamdom as Murphy and his laws is the KISS formula: Keep It Simple, Stupid. When general considerations are at stake, most of us believe in KISS. It is when we pursue solutions to personal problems that we frequently lose sight of the fact that "simple" usually is best. Here's a case with some general and specific lessons which may be of value.

I blew my bank account recently for an ultracompact cassette recorder with the ruggedness and frequency response I need as a writer. The Sony TC-150 worked beautifully from the beginning, but the carbon-zinc AA-cells didn't last through even the first interview. The company wanted nearly $50 for rechargeable batteries and an automobile adapter, so I decided I might do something cheaper.

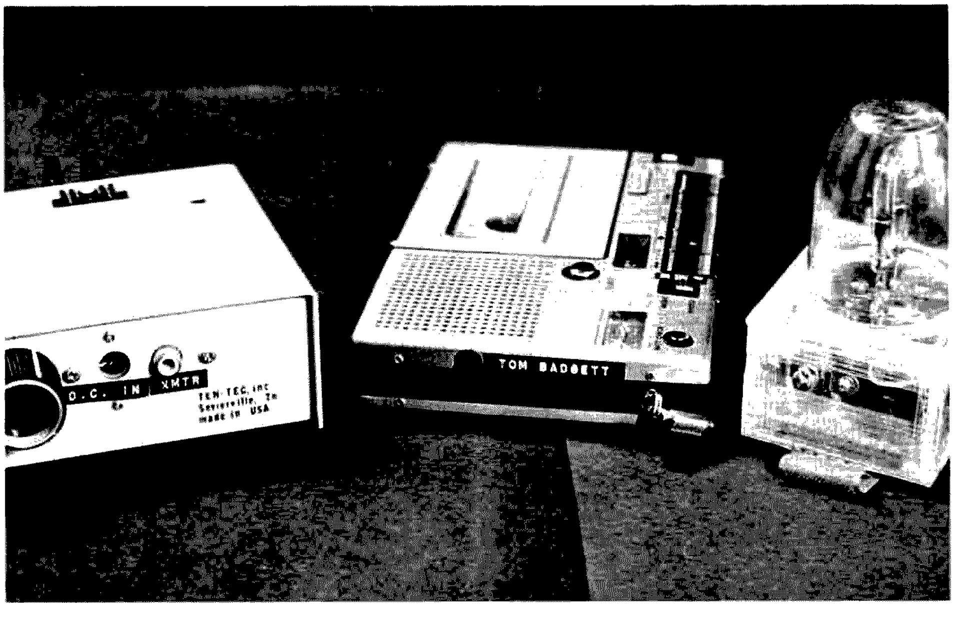
I solved the automobile converter problem first. The circuit in Fig. 1 reduces the vehicle's 12 volts to the six volts my recorder needs, gives excellent voltage regulation, smoothes out spikes and hash which might be generated by the electrical system, and provides recorder protection in the event of failure of any of the converter components. With junk-box parts, the total cost was around two dollars.

The circuit is a fairly common one, using a zener diode to control a pass transistor. One of the three-terminal regulators probably would handle all the current of most recorders or similar devices and would be simpler still. As shown, the circuit draws about 12 mA with no load across C-D, so, if I forget to unplug the unit from my car's cigarette lighter, there's no real harm done.

Naturally I was concerned about the safety of my $200 tape recorder, so, once I got the converter functioning, I shorted and opened leads while monitoring output voltage. Nothing I did produced excessive voltage at C-D. I had first experimented with a simple zener-resistor regulator, but found that such a circuit could deliver 12 volts to my six-volt recorder if the zener opened. With this circuit, an open zener simply will stop conduction through Q1. A shorted zener drops the output voltage to zero (and might blow a fuse in your car's electrical system). Should R1 short, the output voltage will rise a few tenths of a volt and probably cause excessive current to flow through VR1, but still no harm is done to the recorder. A short across any of the terminals of Q1 produces a slight rise in output voltage, but less than a one-volt increase was observed. Apparently the circuit is a safe one.

Obviously, it took some experimentation and breadboarding to get this circuit "perfected." Guys with more design experience could come up with a better circuit a lot quicker. But when I let KISS take over and studied the problem somewhat more objectively, I found another solution—one which made all that experimentation and design obsolete.

Even with the converter,



Here's some of the equipment I regularly power from a six-volt lantern battery. The keyer (left) is a Ten-Tec KR-1 paddle assembly with an Accu-keyer squeezed inside. My tape recorder is in the center, and on the right is a compact strobe I strap to my bicycle luggage carrier when I'm caught out after dark.

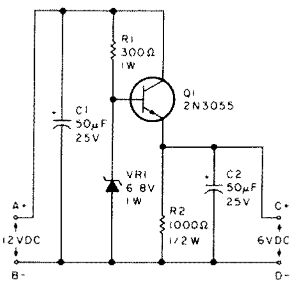


Fig. 1. Dc-to-dc converter.

I hadn't addressed the real problem: How can I have long-lasting battery power to record extensive interviews? Frequently I want to interview people outside, moving from room to room, or in an office situation where access to the mains isn't easy.

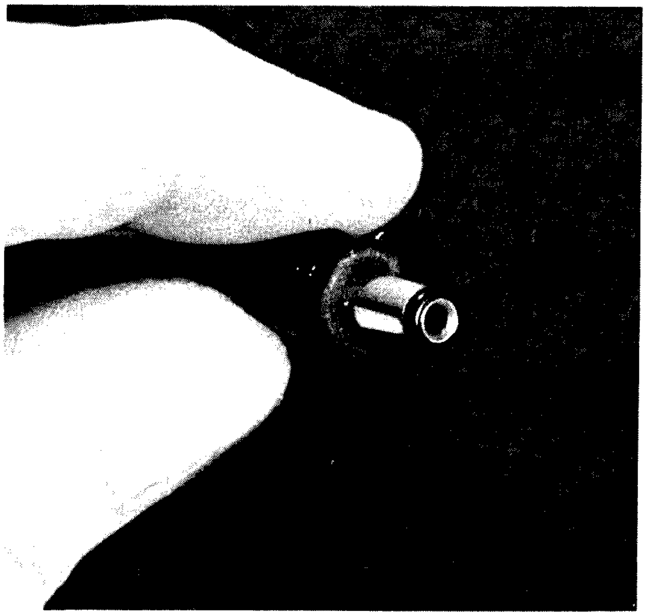
I checked several industrial and specialty battery suppliers for a rechargeable AA-cell which could deliver more than the 500 milliampere hours so commonly available. Apparently that's the largest AA-cell made and four of those will run my recorder less than three hours. It isn't unusual for my machine to run eight hours or more some days. Besides, these cells take anywhere from 5 to 12 hours to recharge, time I sometimes don't have in my business.

My recorder has an external dc input jack. I was using it with the ac converter in my office one day when the light dawned. I almost always carry the recorder in a small briefcase, so why must the power be self-contained? I found a plug to match the machine's dc input terminal and hooked it up to a six-volt lantern battery. I had found the (almost) ultimate long-life portable power supply.

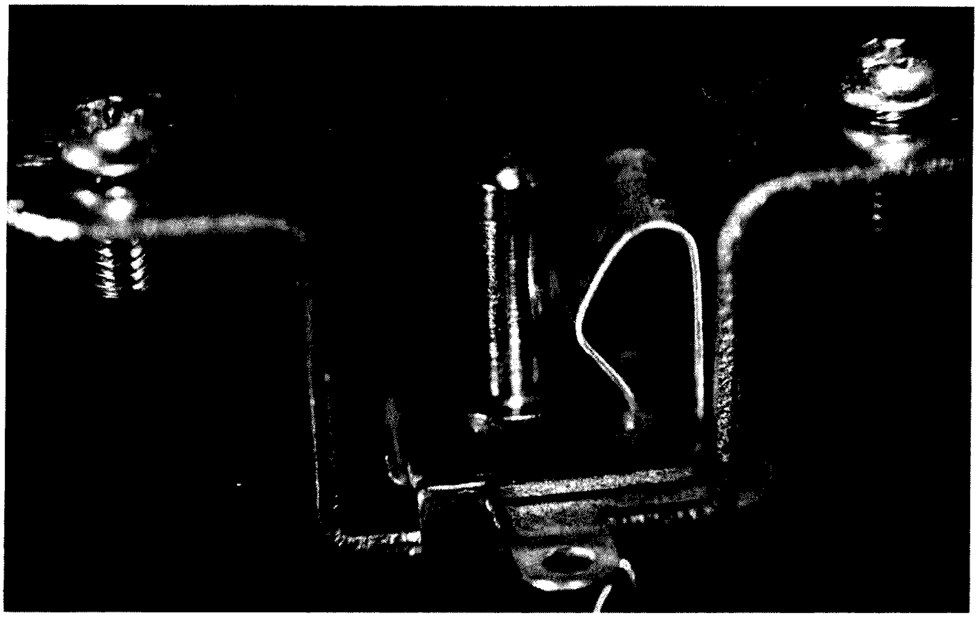
These batteries are rated for about five Ampere-hours. My tape recorder draws 150 mA during playback and record and 300 mA with the motor stalled after rewind, a short-term condition. I was getting over 30 hours of continuous use from each battery at a cost of less than two dollars. Since I was carrying the battery anyway, I no longer needed the automobile converter I had worked so hard to design.

Then other benefits became evident. This lantern battery with its power plug became a very useful bench supply. Cautiously at first, then with an increasingly cavalier approach, I began using the six-volt battery to power my five-volt circuits. I haven't found anything that couldn't take the slightly higher voltage with no harm. It is especially suited to power CMOS devices with their low power drain and wide voltage ratings.

I've improved the system now. I replaced the original dry battery with one of the new Gould rechargeables. With ac charger, interchangeable screw terminals, and spring contacts, the battery costs around $20, but it is worth it. Now when I build up a new project, I automatically install one of the little chassis-mount power plugs so common on tape recorders. They're available from Radio Shack and others for about four bits. They have an extra contact, so the internal supply (if one is installed) is disconnected when the external plug is inserted. Even with heavy recorder use and multiple uses around the shack, my six-volt rechargeable only has to be charged about



This tiny power plug attaches to lots of my ham equipment these days. Remember when wiring up one of these that the positive side is the outside of the barrel and the center conductor carries the negative current.



A close look at the chassis-mount jack that's going on more and more of my projects. Note the spring-type switch that can be used to disconnect an internal power supply. These jacks come with .085" or .097" diameter center posts. Most recorders use the smaller one, but I've found that some of the mating plugs can interface with either size. For some applications, you may have to isolate this jack from ground because the ground side is the positive side; the center post carries the negative current.

The ultimate in portable power: a six-volt, five Ampere-hour rechargeable battery. It comes with ac charger and interchangeable terminals for around $20.

every three weeks.

Now I'm a lantern battery convert. I don't see how any ham shack can get along without one. If you shop the discount houses, you can pick up the nonrechargeable version for a couple of bucks and you're buying a lot of power for your money.

But for heavy use, I recommend the rechargeable battery as a better buy. Mine lasts so long I've given up using my ac converter altogether. In fact, I even use the battery with my recorder when I'm loading and dumping programs from my home computer.

Hardly a day goes by when I don't find some useful purpose for the six-volt lantern battery, and that always reminds me of the time I wasted solving my portable power problem until I KISSed it. ■

David J. Brown W9CGI
RR 5, Box 39
Noblesville IN 46060

As a follow-up to my original article on Autotrak (*73 Magazine*, July, 1977), this article will reflect what a year's change in overall use, my continued system development, and a lot of reading have done for the original system. "Had I only known then . . ." seems to be an adequate phrase because the new system is as different from the old as night and day are from one another.

The Autotrak II system performs the same chore of aiming celestial-type antennas (El-Az mounting) to chase such things as the moon or OSCAR, but does so with some vast improvements over the old system. Some of these are:

1. The BCD entry system from the antennas no longer needs the BCD or gray-code-encoded "wheels" of the Autotrack I, and, therefore, is easier to set up and adjust. It uses, instead, the 500-Ohm pot found in nearly all commercial rotators sold today—no BCD wheels and no extra control or sense wires!

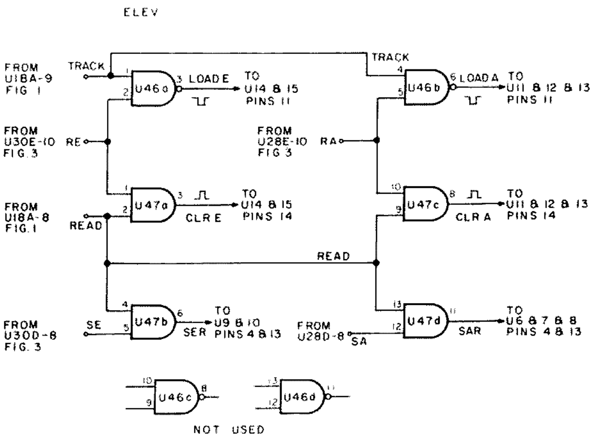
2. The system has good resolution (crystal timebase) and is very temperature stable, as all systems electronics are indoors at a relatively constant temperature, as opposed to those which are outdoors at the antenna end.

3. There is a large reduction in hardware, especially if you leave off the "frills" of Fig. 5. If you don't want the automatic feature, but do want accurate setting (BCD switches) and digital readout (7-segment LEDs), the circuit becomes even easier by eliminating most of Fig. 6.

4. My sincere thanks and credit are due to W6URH and his article in the November, 1977, issue of *Ham Radio* magazine. The article was on a digital locked receiver, but the counter scheme really got me thinking about its use in my Autotrak system. If you compare the two articles, you will no doubt see the striking similarities.

5. There was one major system fault which held up improvement until now. If you use any kind of pulse counting (ratchet wheel and microswitch at the antenna, etc.) system, the whole thing comes apart when you get to the counter part. If a ratchet were used, what would happen when you returned days later and turned power on? A memory, perhaps?—no, because of cost and constant power drain. Add that to a 90:1 change in elevation, or 360:1 change in azimuth, and vco's seem ruled out, too. But, in truth, they are not. You only have to use them properly, and the ratios suddenly become far less.

6. Finally, an idea I used in an earlier device to make a highly versatile tachometer circuit and a method used when counting low frequencies struck home. If you choose a good stable timebase of the right frequency as the "counts," or degrees, and allow the count gate time (period) to vary, a whole new picture develops. I have done just that on Autotrak II. The timebase is a crystal-derived 20 kHz, or 1 pulse per 50 μs. By making the window the right width, the right count occurs.



IC		Pin Vcc	Pin Gnd
U46	7400	14	7
U47	7408	14	7

Fig. 1(a).

7. Further, I do run vco's for both elevation and azimuth. The 566 IC can easily change frequency 2:1 on the modulation input pin alone. By choosing the right frequency for the vco clocks and gating properly, 2:1 windows are formed which count just what you need for proper readout. The count is never zero. (I'll cover that better further into the article, but, for now, just be advised that that solves all my linearity and VLF-vco problems.)

Since a counter scheme started the whole ball rolling, that seems to be the logical place to begin my system explanation. If you consider just U11, U12, and U13, or U14 and U15 with the gating of U16, you have very simple 3- and 2-digit frequency counters, respectively. U16 is the count gate, and, for the moment, I will consider only up counting as you are used to seeing in frequency counters (U16b and c). As I mentioned, the same 20 kHz timebase frequency is applied to both the azimuth 3-digit and elevation 2-digit counters through U16. This is true in both up and down counting. The count gate window is formed by the externally generated frequency, much the same as period counting in a period/frequency counter is. Ignore the preload lines with SWs connected to them and the load lines' pin 11 for the moment. You have then a simple up counter that "reads" X number of 20 kHz pulses depending on the window period, which depends on the vco frequency, which in turn depends on the antenna position and 500-Ohm rotor pot.

The generation of timing I will cover in detail in discussing Fig. 3, so, for now, I'll just give a sequence. The gates produce a count period, then a strobe period, then a reset period, and, last, an unused period (x). The entire sequence is repeated over and over. The period of each window and the overall sample period is determined by the particular controlling vco. As an example, look over Table 1, and note that the elevation vco runs at 100 Hz for 00 degrees and 50 Hz for 100 degrees. In order not to have the vco ever have to go to a zero frequency, I decided to

have it go from 100 Hz (period .01 seconds, count window = p/2 or .005 seconds, 100 counts of a 20 kHz signal) to 50 Hz (period .02 seconds, count window = p/2 or .01 seconds, 200 counts of a 20 kHz signal) and ignore the 100's digit. This produces a 00 (100) to 99 (199) degree readout if you take the 100's digit and further ignore the 00 (200) for now. It is detected and taken care of by other means.

So the counter counts for the count period the proper number of counts representing a degrees position of the rotor pot. That's normal frequency counter operation. Remember that there are two separate and distinct counters at work and that they work in identical ways, and you won't get lost. During the strobe period right after count, the BCD information is passed from the outputs of U11, U12, and U13 to the outputs of U6, U7, and U8 for azimuth, and from the outputs of U14 and U15 to the outputs of U9 and U10 for elevation. Remember the two independent counters. The next period is reset, and, neglecting the how for now until we get to discussion of Fig. 1(a), this generates a clear (⊓) pulse for pins 14 of the counters. The up counter mode is called the "read" mode because that is just what you do. The read mode counts the antenna position, and via U1, U2, and U3 for azimuth and U4 and U5 for elevation, displays it in the proper readout. That sums up the up counter/read mode. It is merely a "Where am I at?" function.

Still in Fig. 1, you have no doubt noticed that the 74192s possess a few lines and functions which are missing on the more familiar 7490/7493 family. These include the load line and preload lines connected to the SWs I had you ignore and a down counting function. Starting with the latter, in an up-count-only-type IC, only one IC input is needed for two reasons—one, you are only counting one way, and two, the counter "knows" when it fills up (counts to 10 in a decade counter) to pass a 1 on to the next MSB counter as an up count or "carry" function. For the same reasoning, an up/down counter must have two inputs—one each to count each way, and two more to tell the next MSB to add a 1 or to subtract it. These further two lines are called "carry" and "borrow," respectively.

For the first down counter example, let's consider that all the SWs are decimal (0-9) reading and BCD output switches very common on the market today. You can set in a number desired (azimuth and/or elevation) in the 0-9 form you are used to using (ten-position switch), and the outputs are 4 BCD lines from each switch. When you connect these at the SW positions, BCD information for where you want to go is available to input on the preload lines of the 74192s. Since the down counting occurs in what I call the "track" mode, look at the bottom of Fig. 1 and I'll explain how to get to that mode.

To the far right of the schematic is a push-button momentary switch. Each time it is pushed, you change modes from read, to track, to read, etc. Pushing the push-button produces a clean TTL pulse out of U17d-11 to the U18b-3 clock input. U18b uses the leading edge of the pulse to put into the Q-output whatever is on the D-line at that time. The D-input, in this case, is merely the $\overline{Q}$-output of U18b-6. If U18b is in $\overline{Q}=1$, then Q becomes 1, forcing $\overline{Q}$ to 0. If U18b is in Q = 1, then $\overline{Q}$ = 0, and Q becomes 0, forcing $\overline{Q}$ to 1. It's a simple toggle switch. If this high in one mode

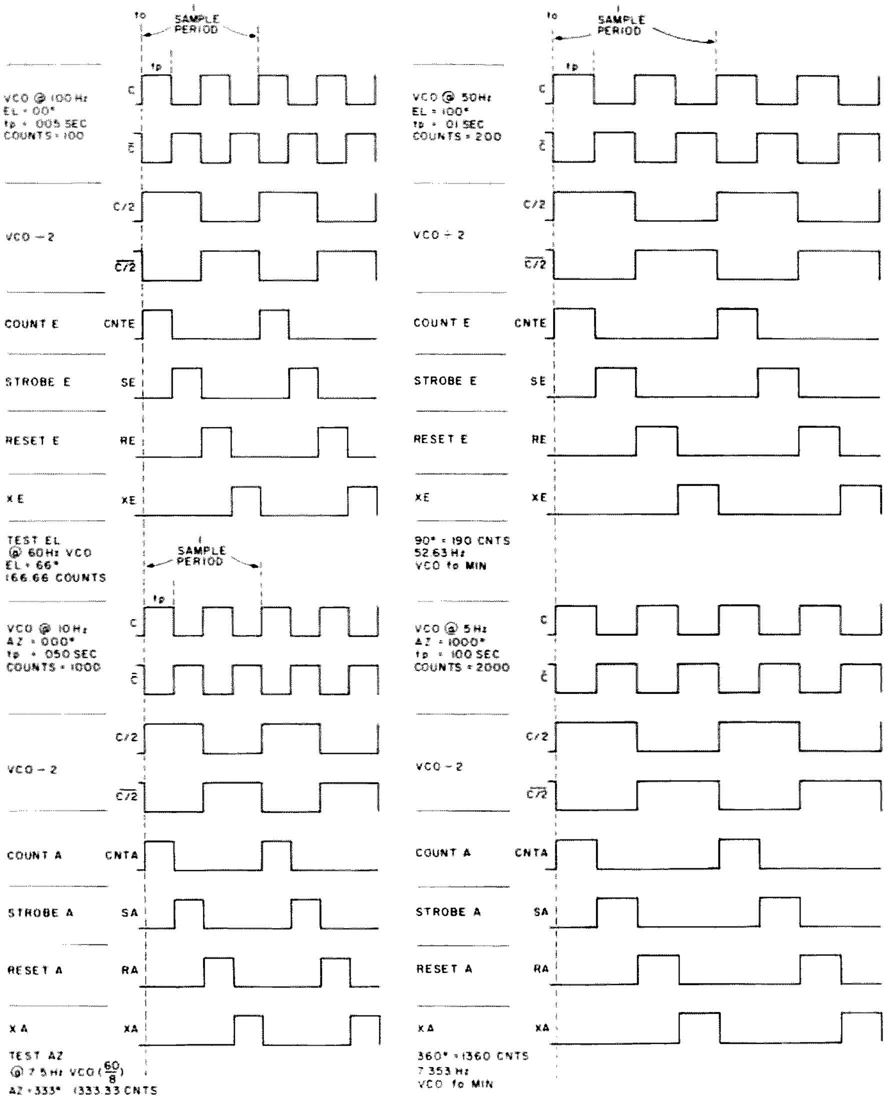


Table 1. Timing chart.

and low in the other mode were directly used to control the read/track mode changeover, all kinds of strange things could happen in counters, latches, and readouts. Remember, in a counter of any kind, timing is everything! I keep the strange things from happening by using the other half of U18 to determine when the mode change will occur in a sample period.

Start in the read mode you were in. A count period occurs (up counting the counters), and the strobes cause independent loading of the 7475 azimuth and elevation latches. Now, when both counters are in the reset period (data all locked up for the counters and readouts), and only then, does the U18a put the level on its D-input (output from U18b-5, high for track, low for read) onto its outputs by forcing its Q-output to go to D-level (input). When U18a-9 (Q-output) is high, the $\overline{Q}$ on U18b-8 is low. This enables the down counter gates and disables the up counter gates.

Since you are in the reset part of the sample period, the gating of Fig. 1(a) causes two things to happen. First, the strobe that has been causing the latches to pass data to the readout is disabled, causing the readouts to continuously display where you were when the mode button was pushed to the track mode. Also, the reset line is rerouted and used to cause a load command. The counters are no longer cleared, but rather preloaded in the reset period. As you are in the reset mode now, the contents of the BCD switches (SWs) are loaded into the counters directly, just as though you had counted to get there. Next comes the extra period (x) where nothing is done, and then it's on to a new sample period.

When the next sample period begins, the counters are already loaded with a number. Let's use azimuth and the SWs set at 180 (degrees—due south). Suppose further that the antennas were at 270 (degrees—due west). The display will remain locked up at a 270 readout during the entire track mode operation, since strobe is disabled then from getting to the latches. The gates have switched to down count, and the number 180 has been entered into the counters during reset (a load command when in track mode). The first operation of a new sample period is count, and so the counters begin counting down. Note that the count gate will be long enough to allow 270 counts to pass. This causes the MSB counter U11 to "underflow" and generate a borrow command normally used to steal a count from the next MSB counter. There is no such counter here, so it is used to operate other control circuitry we can now begin to cover in Fig. 2. Let's stay with the azimuth example.

The borrow pulse enters U20c-10 once for each sample period that the antenna readout numbers exceed the desired switch input numbers. Borrow is a negative-going pulse (⊔) that causes a positive-going set condition on U20c-8 if it is not already set. The previous $\overline{RA}$ into U20d-12 assures this is the case. The leading edge of the positive-going sets condition clocks U22-3 and causes the $\overline{Q}$ output U22-6 to go low. This low is used

to clock a one-shot, U24a, to output a positive-going pulse at U24a-13. This one-shot period is made longer than a 1-degree change in the rotor (or 166 ms) to give a carryover effect from degree to degree. Since this departs from the original author's ideas, here's why:

The original system used in a receiver used these output-pulsed lines from U21 and U22 to control devices which charged or discharged a capacitor whose dc voltage was used to control the vco of the receiver—hence it had digital afc. Since I am controlling relays and did not want them pulsing on and off rapidly at the sample period rate, I use the one-shots to stretch the pulses into a long enough period to hold the relay closed from degree to degree. If triacs or the like were used and the rotator used did not object to pulsed power, the pulse stretchers would not be needed. Since I already had the relay panel in the Autotrak I system and didn't know the rotator motor's nature about pulsed power, I went my way.

In my example, the CCW relay would pull in. CCW refers to a top view of the antennas. CW does the exact opposite. In elevation, the up/down terms are self-explanatory, with 00 being straight ahead and 90 being straight up. CCW is the desired result in our example, and the antenna degrees begin decreasing with the sample period until the count just equals preload (180 = 180). At this time, no borrow pulse occurs. Due to the timing of gate U20 and the control lines to U21 and U22, this condition (=) causes no pulses out of either the CW or CCW part of U22—no pulses, one-shot period runs out, relay drops out, and antenna stops. How we get back to read and a proper display will be covered later.

Changing the example slightly, make the SWs the same 180, and change the original antenna position to 90 (degrees—due east). I am using large examples to show that several sample periods occur. For the antenna to turn either way through 90 degrees of both examples takes about 15 seconds in the average 1 rpm rotator. This is many ms-type sample periods. When the antenna position in degrees is less than the desired SW input in degrees, the following occurs. First of all, you enter track mode the same way, and strobe disable, countdown enable, and preload take the place of clear. Track mode is the same for both ways of rotation, with only the down count result changing. If the 180 figure is preloaded into the counters during the first period of resets (load), then, during the next sample period first window (count), the counters will again count down. This time the count window only allows fewer counts to be counted down than the

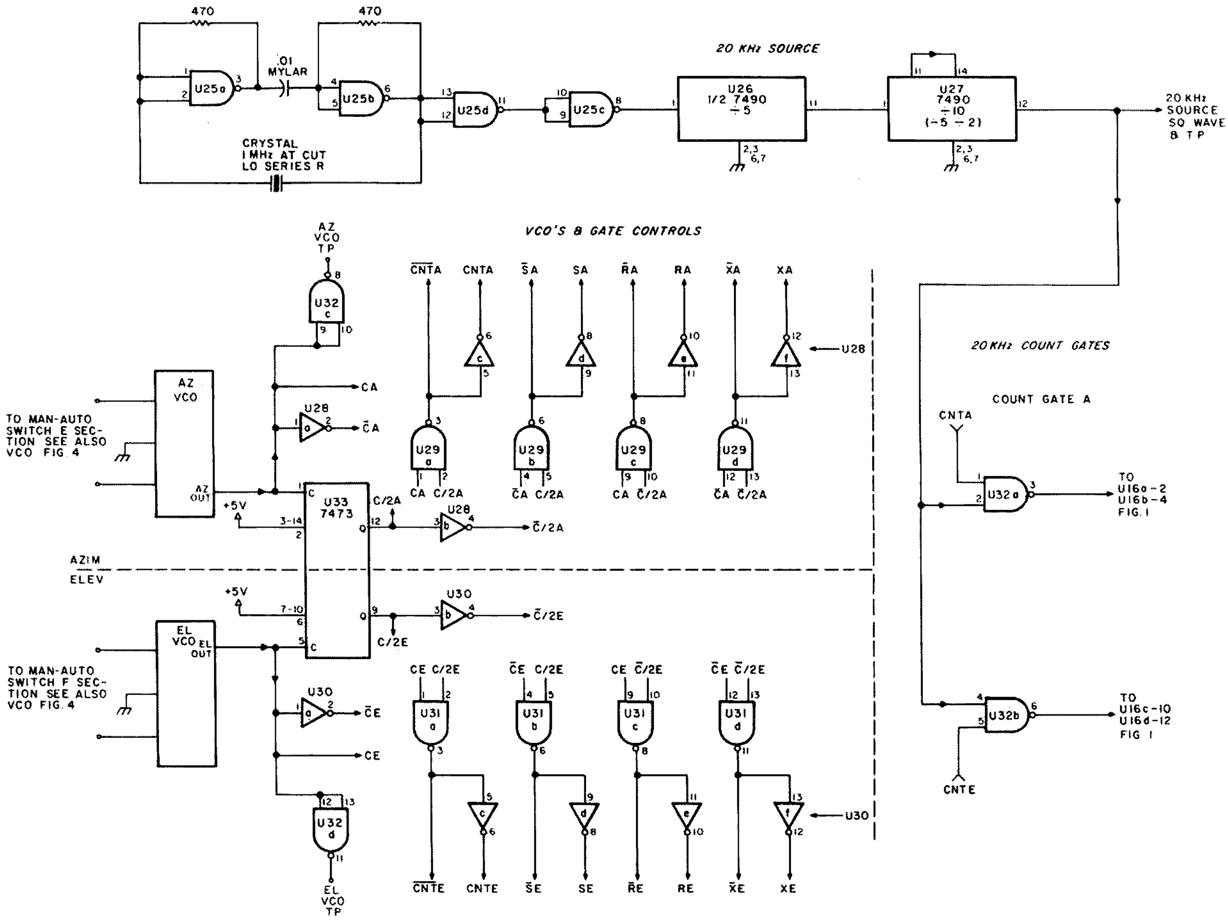

Fig. 3. Vco's and gate controls. U25—7400; U28—7404; U29—7400; U30—7404; U31—7400; U32—7400; U33—7473. ¼ W film resistors.

preload figure, and no borrow pulse occurs. With U20d-11 now in the set (high) mode, the reset line U22-13 allows U22-8 to toggle low whenever a clock pulse comes along on U22-11. This happens during the strobe period following a countdown, and the leading edge of a pulse (strobe) toggles U22-8 low. The one-shot follows through as before, using U24b this time, which turns on the CW relay. CW is increase azimuth degrees, and the antennas drive toward 180 from their 90 start point. When 180 is reached, again the (=) exists and the antennas stop. Whenever the (=) exists and the track mode is entered, the timing of U20 and U22 is such that no relay pull-in occurs. That completes a run through for azimuth.

For elevation, exactly the same events occur, but on a 2-digit counter group. It is as simple as that. What you have is a complete duplicate counter set for elevation from what an azimuth-only setup would be. For just that reason, you could very well build the azimuth-only version for normal on-the-ground communications not requiring elevation changes on the antennas. You cut everything just about in half except the read/track mode circuitry. You would have one 3-digit counter set, all the read/track circuit, half the antenna control (U20, U22, U24, and U19e and f), CW/CCW relays, one vco (azimuth), the same 20 kHz timebase, and whichever switch option you want from Fig. 6.

As usual, I have left for last the best and most important part of the explanation of Figs. 3 and 4. Fig. 4 is just a detail drawing of the vco part of Fig. 3. On Fig. 3, the easiest part to cover first is the timebase, and it is very straightforward. A quite common TTL oscillator uses a 1 MHz crystal that you can trim by using one of the harmonics beat against WWV if you desire. I did not trim mine, so no trimmer is shown. Remember that you are dividing by 50, and, if you send any reputable crystal manufacturer the circuit schematic, the error in the crystal will more than likely be erased by the divide-by-50 process. Also, you have control over the count windows, so you can fudge things there for small errors if need be. I didn't have to, as the crystal I got, when plugged into the circuit, ran at 1.00000126 MHz (divided by 50 = 20.00002520 kHz). The error is further spread over all 20,000 Hz, and only a small part (4000) is the maximum ever used. Resolution is resolution, but don't get ridiculous! The clock out is applied to the count gates as a fixed 20 kHz signal.

Jumping to Fig. 4 briefly, the vco's are quite standard use of the 566 vco, so I won't go into any more detail than the formulas and tips supplied on the figure. Suffice it to say that the elevation vco outputs 50 to 100 Hz, and the azimuth (due to an added divide-by-10) would put out 5 to 10 Hz were it not for the setup. That will be covered in the Fig. 4 notes and the calibration procedure.

Back on Fig. 3, and again using azimuth as our example, the 7+ to 10 Hz coming from the azimuth vco is applied to four places.

IC	Pin Vcc	Pin Gnd
U33	14	7
U34	5	10
U35-36	8	1

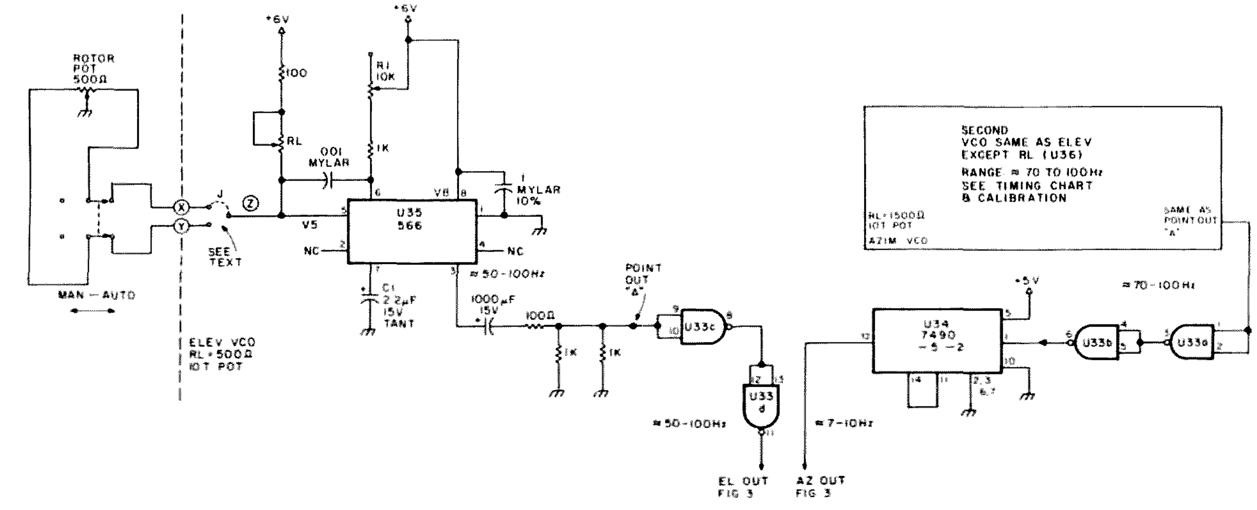

Fig. 4. All resistors are ½ Watt metal film for temperature stability, 5% tol. U33—7400; U34—7490; U35-36—566. Vco formulas: $f_o = 2(V_8 - V_5)/(R1C1)V_8$.

With V_5 gnd (by rotor pot) and RL_{EL} set at 400 Ω:

a. $f_o = 2(V_8)/(R1C1)V_8 = 2/R1C1$

With V_5 + 3 V (rotor pot set at 500 Ω) and RL_{EL} set at 400 Ω:

b. $f_o = 2(+6 - 3)/(R1C1)6 = 1/R1C1$

c. With R1 set at ≈9091 Ω and C1 = 2.2 uF, $2/9091(2.2) \times 10^{-6} = 99.999$ Hz (≈100 Hz).

d. With R1 set at ≈9091 Ω and C1 = 2.2 uF, $1/9091(2.2) \times 10^{-6} = 49.9995$ Hz (≈50 Hz).

e. For azim., R1C1 same, RL = 1500 Ω, part a. same for 100 Hz ∴ ÷ 10 for 10 Hz frequency. Low frequency = 1360 counts x 1/20 kHz = .068 sec. CNT a. For .068 sec. CNT, period = 2T (or 1 cycle) = .136 sec. 1/period = 7.3529412 Hz. That frequency = 73.529412% of 10 Hz. If V_5 = 0 V is 100% and V_5 = 3 V is 50%, 0 V > V_5 < 3 V is 73.··· %. 73.··· % of 6 V = 4.4117647 or V_5 = 6 − 4.41··· = 1.5882353 V = V5. V_5/500 Ω = 3.1765 mA. V_{RL} = 4.41··· ∴ $V_{RL}/I = RL_{(total)}$. $RL_{(total)}$ = 1388.89··· Ω − fixed 100 Ω = 1288.89. Set RL at ≈1290 Ω and follow calibration to trim.

U32c is merely a buffer whose function was not needed for anything else and whose output is a frequency counter test point (TP) for vco setup. The vco output becomes one of four gate primary signals, Ca, and, via inverter U28a, a second gate primary signal, $\overline{C}$a. Through a divide-by-2 stage, U33, the Ca signal becomes C/2a, and, via inverter U28b, the last primary gate signal $\overline{C}$/2a. These four commands are further gated in U29 to form four distinct and separate low periods during any sample period and, via the rest of the U28 inverters, the high period inverses of the four periods. Not all are used, as you will see, but, when I build timebases and control circuits, I like to allow for future plans and expansion. As an example, the $\overline{\text{CNT}}$ a is not used, but it is what is detected, and it must be then inverted to get the CNT a needed. These gates and inverters are the cheapest TTL available, so "spend a bit more and keep versatility" has become my motto!

All the required signals for count (CNT), strobe (S), reset (R), and an extra (x) are formed in both polarities by U28 and U29. The elevation is a carbon copy derived from the elevation vco frequency and is used to control the elevation counters and gates. (Incidentally, the little letter a denotes azimuth, and the letter e denotes elevation, just so you can follow the schematics more easily.)

At the proper time, the CNT a (⎍⎍) is applied to U32a-1 to pass 20 kHz to the azimuth read/track gate. The same goes for CNT e (⎍⎍) and the elevation read/track gate. And that's all there is to Fig. 3.

Fig. 5 contains circuitry that may prove necessary to some, options to others, and maybe crazy to yet a few more. I, quite frankly, did not use the "El stop" and "Az stop" circuits. They are preventative medicine. They form positive electronic stops to avoid the almost nonexistent errors that can occur. Using the calculator inputs, I will explain with Fig. 6 the limits of the formulas and the calculator ICs I used. No answers over 90 degrees elevation or 359 degrees azimuth will occur anyway after the program is up and running right. On the manual switch entry version, in elevation, you only have enough switches to enter up to 99 degrees (two switches), so there's no problem, as 00 to 99 degrees are all legal commands in this system. In azimuth, you can only go from 000 to 360 degrees (mechanical stops), but the switches required (three switches) allow a manual entry of all that plus from 360 on up through 999 de-

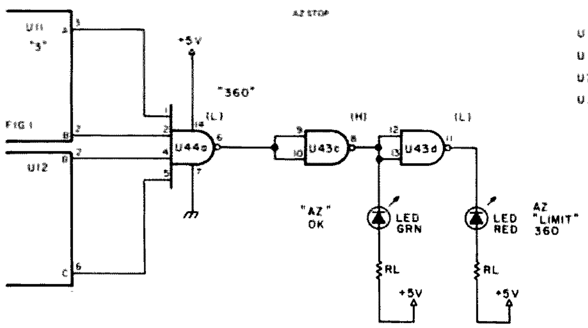
PARTIAL PANEL LAYOUT



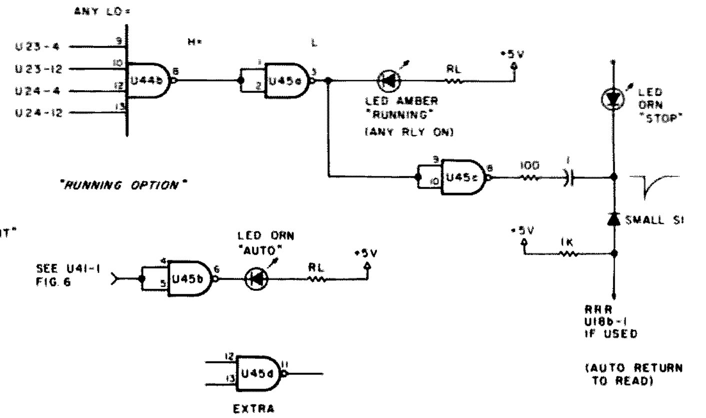


Fig. 5. Mechanical stops handle 350° stop, but, in automatic, the detector U44a-b also shuts off rotor ac via the CW relay and U24 off ($\overline{Q}$s). Handles false calculation data or error in SW entry, e.g., 400°.

grees. So either build the circuits, or watch your entries. If you don't build them, be sure to connect the RRe and RRa points of U23 and U24 (Fig. 2) to +5 volts.

If you add all the extra goodies, a suggested panel layout for a quick look and understanding is shown in Fig. 5. It is neat and quite usable in this fashion. I would include at least the LEDs of Fig. 2 for direction running, U45b if the auto entry of Fig. 6 is used, and the U44b and U45a "running" pair of IC parts.

U45c is nice if you want to automatically return to read mode when both antenna rotators reach their desired location. This isn't important in full automatic, because you won't be looking at the readouts at all except as a check if something suddenly goes afoul. U45c just puts a small reset pulse on the read/track line in place of your finger when all the U44b inputs return high. This drives U44b-8 low, U45a-1 and -2 low, U45a-3 high, the "running" LED off, U45c-9 and -10 high, and U45c-8 low. This causes a small negative-going pulse at the junction of the LED, the general-purpose silicon diode, and the .1 uF capacitor. This blinks the "stop" light (LED) and pulses the read/track line back to read via U18b-1. This allows the counter and readout to update to the new location in degrees.

Fig. 6 covers another option—a very, very useful one that started all of this automation. The 2-line to 1-line IC switches shown allow the preload entry to come from two separate places, depending on the position of the manual/auto switch controlling the select lines U37 to U41, pins 1. When grounded, pin 1 allows the ICs to pass the BCD data from S1 to S5 to SW1 to SW5, respectively. In other words, you have direct entry by manual thumbwheel switches. If you don't want anything else, follow the notes of Fig. 6 and delete U37 to U41.

When pin 1 is high, it allows data to pass to the preload lines from a second source. This may be interesting to some just as a way to run one antenna from two "control heads," both of which would be thumbwheel switches. In my case, the data comes from other 7475 latches. At first, these were the entries like those used with Autotrak I. Now they are entries from a calculator device I put together and called a Calcuputer, for lack of a more descriptive term. It starts as a basic hand-held-type of RPN calculator by APF called a Mark 55. The calculator set of ICs is by Mostek, as are the MK50075N, MK50103N, and 50104N. I wrote a program (sequence) to follow OSCAR by punching in sequential keys on this calculator and cranking out answers. That then led to automating the whole thing with a few more ICs. For the sake of explanation here, it boiled down to the answers for elevation (2 digits) and azimuth (3 digits) being dumped out on command to (5) latches, where they are held until needed.

I use a timer IC that outputs two control pulses 1 minute apart and staggered by 30 seconds. The sequence of operation is as follows: Pulse 1 (P1) occurs when I push a button exactly when OSCAR crosses the Equator (from published data). The Calcuputer has been given the Eqx longitude prior to this, been allowed to calculate the El-Az for T1 (Eqx plus 1 minute), and has outputted to the (5) latches. When the next pulse comes along 30 seconds later, it strobes this information into the preload lines and then triggers the read/track to track mode. Then, 30 seconds later at T2, the Calcuputer is started again and uses the new T = 2 minutes input for new answers which are dumped out into the latches. This sequence is repeated over and over through the T maximum you choose.

I want to explain the other inputs as well. They can also be used to return the antennas to a preferred storage position when you are through operating (into the wind, toward town or a favorite DX direction, etc.) or even tied into the digital wind indicator, as I mentioned earlier in an article on digital wind instruments (*73 Magazine*, Nov., 1976, page 84).

For our small group of EME enthusiasts around the Indianapolis area, this dedicated input control method puts our repeater idea one step closer to remote control of my station antennas very accurately from a remote Indianapolis user's location.

The whole EME station at my QTH was designed around digital remote control, mainly because analog information is a bear to convey or compare. Speak-

IC	Pin Vcc	Pin Gnd

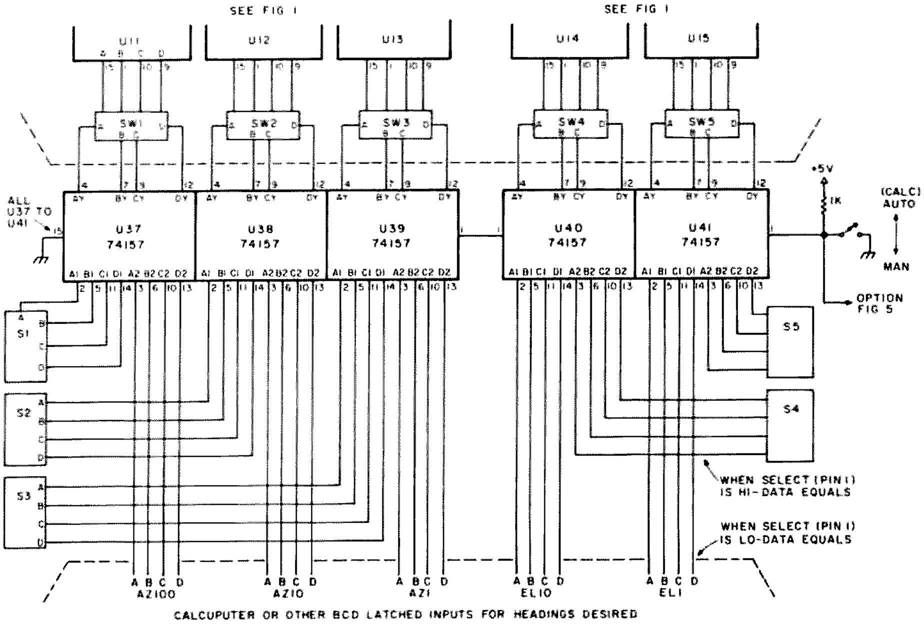

Fig. 6. S1 to S5 are read 0 to 9, BCD output T.W. switches. If manual SW only is desired, connect S1 to SW1, S2 to SW2, etc., and S1a to SW1a, S1b to SW1b, etc., and delete U37 to U41.

ing of digital, I fully believe EME should really pick up soon. Between the narrowband SSB article in a recent *QST* issue and another article on coherent CW which I was already working on (but confess I was not nearly so far along with), the modes of the future all point to narrower bandwidths and are almost always digital in nature. I give as my witness the above NBSSB and CCW examples, backed up by (digital) frequency synthesized receivers so you know exactly what frequency you are on, the (digital) very narrow tracking filters tuned by just adjusting a variable oscillator into them, and the forms of afc tracking receivers such as that on which my hardware is based.

To close this article, may I issue a small challenge to all you dedicated remaining builders—especially the digital IC types? How about the feasibility (and it would seem to be very inexpensive even at TTL prices) of a fully digital transmit and receive system for weak signal work? (1) It should include a synthesis scheme for all the transmitter and receiver (transceive) operations. (2) All of the filters and bandpass (i-fs, bfo, etc.) devices should be digital tracking types. (3) It should have a lock or afc mode such as the one I started with here. (4) It should be locked to, traceable to, or have a countdown scheme involving a reliable master oscillator determining the operating frequency (i.e., WWV, CHU, etc.). (5) The digital readout and display should go down to cycles or, at the very least, 10s of cycles is a must. (6) It should use coherent CW and very narrowband SSB or FM as modes, and the FM detector should be a digital pulse counting type (the FM for inherent AM noise immunity which even improves in a digital system as all transitions are saturating, eliminating AM just as a limiter does). (7) The transmitter should run class D (digital) switching for fairly high power output out of low power devices (they are on or off and therefore dissipate little power themselves). (8) The class D goes for the audio outputs in the receiver as well. (9) Readout must employ mixing of hfo, lfo, and bfo oscillators to give an exact frequency out reading. (10) Oscillators should be vco's so that a dial input can be used.

Is this ten times an impossibility? Not on your life! All the above is available now and at a TTL-type of expense. Now who is going to be the first to build one? (P.S. If you think I'm just kidding, mine is half done!) ■

Table 2. Calibration/setup.

Use a well regulated +6 volts on vco sections and good quality parts. Vco elevation :: Rough set R1 = 8100 Ohms.

1. With RL rough set to around 400 Ohms, run elev. rotor and antennas to 00 degrees elev. This will be a mechanical rotor stop, so set it accurately using a level.
2. Measure X to ground and Y to ground and insert jumper between Z and the X or Y terminal that reads zero (0) Ohms to ground.
3. When Z to ground is zero Ohms, V5 is 0 volts, and the vco runs at its highest frequency (100 Hz), determined by the setting of R1. (This is the shortest gate period, thus 00 degrees—100 cnts.)
4. Use R1 to set the vco output frequency at TP U32d-11 to as accurate a setting as possible of 100 Hz, by method a or b. Elevation switches should be set to 00 degrees.
   a. A counter hooked to U32d-11 and set for frequency should read 100.00000 Hz or, for period, .01000000 seconds.
   b. In the read mode, the readout should display 00 degrees (100 counts). Check the two extreme settings that get the 00 readout, and set R1 midway between these points. Going to track mode should produce no relay pull-in.
5. After successful completion of (4.), set elevation switches to 99 degrees.
6. Run the elev. rotor to 99 degrees (preferably using a level or plumb bob and protractor). This should place the 500-Ohm rotor pot in the R max position from Z to ground.
7. Using RL to set frequency and method a or b, set the low frequency limit. Pot RL preset to 400 Ohms to start.
   a. A counter hooked to U32d-11 and set for frequency should read 50.00000 Hz or, for period, .02000000 seconds.
   b. In the read mode, the readout should display 99 or 00 degrees (199 to 200 counts). Again, check the two extremes of RL setting to get a 99 readout and set midway between these points. Going to track should produce no relay pull-in on elevation.
8. Return to read mode, and set the elev. switches to 90 degrees. Push to track mode and check antennas for pointing straight up after the rotor stop.

This completes calibration of the elevation portion of the antenna control. The antennas can be checked against a protractor or other mechanical device, weather permitting, at other settings. If the relays are mounted on a separate board and the board is mechanically "floated" (rubber grommets), then the pots should hold accuracy. If in doubt, a drop of nail polish or glue from the shaft to case will fix things up after calibration. Just be careful to use something that can be removed later if need be, and get none down inside the pots.

The calibration of the azimuth portion follows the same general procedure. Set the Az switches to 000 degrees and R1 = 8100 Ohms.

1. With RL rough set at 1290 Ohms, run the azim. rotor and antennas to north through east (CCW). This is one of two mechanical stops and should be done accurately.
2. Measure X to ground and Y to ground and insert a jumper between Z and the X or Y terminal that reads zero Ohms to ground.
3. Same as elev. (shortest gate period).
4. Use R1 to set the vco output frequency at TP U32c-8 to as accurate a setting as possible of 10 Hz, by method a or b.
   a. A counter hooked to U32c-8 and set for frequency should read 10.00000 Hz or, for period, .1000000 sec.
   b. In the read mode, the readout should display 000 degrees (1000 counts). Check the two extremes of R1 setting that produce this readout and set R1 midway between these points. Going to track should produce no relay pull-in.
5. After successful completion of (4.), set azimuth switches to 360 degrees.
6. Run azim. rotor and antennas to 360 degrees (north through west) and the mechanical stop. Check for true north, and, if not, run to true north (some rotors allow 360 + a few degrees). This should place the rotor pot in maximum Ohms to ground position at Z.
7. Using RL to set frequency and method a or b, set the low frequency limit. Pot RL preset to 1290 Ohms to start.
   a. A counter hooked to U32c-8 and set for frequency should read 7.3529412 Hz, but few digital counters can handle the low frequencies accurately, so use period and set RL for a period of .13600000 seconds.
   b. In the read mode, the readout should display 360 degrees (1360 counts). Check the two extreme settings that produce a 360 degree readout and set R midway between these points. Going to track should produce no relay pull-in.
8. Return to read mode, and set azim. switches to 180 degrees. Push to track mode, and check antennas for pointing due south after rotor stop.

This completes the calibration of the azimuth portion of the antenna control. The antennas can be checked at the cardinal compass points N, E, S, W, N, weather permitting, by compass. The view from the ground is really accurate enough for most amateur work, anyway.

Social Events

OAK PARK MI
JAN 7

The Oak Park Amateur Radio Club will hold its 10th annual swap & shop on Sunday, January 7, 1979, from 8:00 am to 3:00 pm, at Oak Park High School, Coolidge at 9½ Mile Road, Oak Park, Michigan. There will be expanded table space, parking and prizes. Talk-in on .52. For information, contact Dave Lefko WB8RGQ, 32252 12 Mile Road, Farmington Hills MI 48018.

SOUTH BEND IN
JAN 7

The Repeater Valley Hamfest Swap & Shop will be held on Sunday, January 7, 1979, at the New Century Center on US 31 in South Bend, Indiana. This event will be held indoors with food service available. An automobile museum and art center are in the same building. Tables are $3.00. Talk-in on 146.13/.73, .34/.94, and .52/.52; 147.99/.39, .93/.33, .84/.24, and .69/.09. For information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616; (219)-233-5307.

RICHMOND VA
JAN 14

The Richmond Amateur Telecommunications Society will hold its Frostfest-II on January 14, 1979, at the Bon Air Community Center in Richmond, Virginia. Talk-in on .28/.88, .34/.94, and .52. There will be a technical symposium, a drawing, and a home-brewers' contest with two divisions, over 18 and under. FCC exams will be administered starting at 10:00 am. To take the exam, mail Form 610 at least five days prior to the Fest to the address below. Commercial exhibitors are by invitation only. There will be an indoor flea market with one table for $2.50 and outdoor tailgate space for $1.00. Admission is $2.50. For information, contact the Richmond Amateur Telecommunications Society, PO Box 1070, Richmond VA 23208.

WAUKESHA WI
JAN 20

The West Allis Radio Amateur Club, Inc., will hold its 7th annual midwinter swapfest on Saturday, January 20, 1979, starting at 8:00 am, at the Waukesha County Expo Center, Waukesha, Wisconsin. There will be food, beer, and prizes. Directions are as follows: I-94 to Waukesha Co. F, south to FT, west to Expo. Admission is $1.50 in advance and $2.50 at the door. Reserved tables are $3.00 (until January 12). For information, send an SASE to WARAC, PO Box 1072, Milwaukee WI 53201.

SOUTHFIELD MI
JAN 21

The Southfield High School Amateur Radio Club will hold its 14th annual Swap & Shop on Sunday, January 21, 1979, at Southfield High School, Southfield, Michigan, at 10 Mile and

Reader Service—see page 227

Lasher. Admission is $2.00. For information, send an SASE to Robert Younkers, 24675 Lasher Rd., Southfield MI 48034, or call (313)-354-8210.

MIAMI FL
JAN 27-28

The Dade Radio Club presents the 19th annual Tropical Hamboree and ARRL South Florida Convention on January 27-28, 1979, in Miami, Florida. Over one hundred exhibitor booths, a giant flea market, and several technical and group sessions will operate simultaneously in completely separate areas of the Flagler Dog Track Auditorium building. With the Convention immediately following the Miami Board Meeting, most Division Directors and HQ officials will be present for the ARRL general session. Extensive free parking, including overnight space for RVs, is available on the grounds. Preregistration is $3.00; $4.00 at the door. For up-to-date information, booth space, flea market table space, RV parking space reservations, and hotel rates, write DRC Hamboree, PO Box 350045, Riverside, Miami FL 33135.

MANCHESTER NH
FEB 10

The Interstate Repeater Society will hold its 3rd annual auction and hamfest on February 10, 1979, beginning at 9:00 am, at the Manchester Armory, across the Amoskeag Bridge from I-93, in Manchester, New Hampshire. There will be commercial exhibits, and the auction will be held rain or shine. Admission and parking are free. Talk-in on 146.52, 146.25/.85, and 224.86/223.46. For information, contact Gary A. Delong WB7NOH/KA1BCA, Interstate Repeater Society, PO Box 94, Nashua NH 03061.

MANSFIELD OH
FEB 11

The Mansfield midwinter hamfest/auction will be held on February 11, 1979, in a heated building at the Richland County Fairgrounds in Mansfield, Ohio. There will be prizes and a flea market. Doors will open to the public at 8:00 am. Talk-in on 146.34/.94. Advance tickets are $1.50; $2.00 at the door. For information, contact Harry Frietchen K8HF, 120 Homewood, Mansfield OH 44906, or phone (419)-529-2801 or (419)-524-1441.

LANCASTER PA
FEB 18

The 7th annual Lancaster hamfest will be held on Sunday, February 18, 1979, at the Guernsey Sales Pavilion, US Rt. 30 & PA Rt. 896, Lancaster, Pennsylvania. Doors will open at 8:00 am and there will be a prize drawing at 2:00 pm. Admission is $3.00, and table reservations are $2.00 in advance. There is a new, larger indoor flea market area. Food and soft drinks will be available. Talk-in on 146.01/.61. For further information, contact SERCOM, PO Box 6082, Rohrerstown PA 17603.

MARLBORO MA
FEB 24

The Algonquin Amateur Radio Club will hold its annual electronic flea market on Saturday, February 24, 1979, from 10:00 am to 4:00 pm, at St. Mary's School Hall on Broad Street in Marlboro, Massachusetts. There is easy access to the Hall from I-149 via Rt. 20 east. Seller setup is from 9:00 am to 10:00 am. Talk-in on .52. Sellers should contact Charlie W1BK at (617)-562-5622.

The Twofer

—double-duty IDer logic

This circuit selects your CW IDer when a repeater is in use, and voice when it isn't.

C. A. Kollar K3JML
1202 Gemini Street
Nanticoke PA 18634

There is much to be said about the advantages and disadvantages of either a voice or CW ID. The best of two worlds would be to have both, with the right one selected automatically according to conditions on the repeater. For example, a CW-only ID is standard in this area, but this approach quickly becomes ordinary and, after a while, no one listens to it anyway. This is demonstrated by the frequent calls on the repeater from transients asking if someone could tell them where it's located. This can be remedied by going to a voice ID which gives the repeater call, QTH, and any other pertinent information. The disadvantage to this approach is the disruptive effect a voice ID has on a QSO. It can get very confusing listening to two voices at the same time. The solution to this problem is the circuit shown in Fig. 1. It has been in use at WR3AGU at Mehoopany PA for about eighteen months and has worked fine.

This circuit gives your repeater "memory" capabilities. While a QSO is in progress, an enable signal is applied to your CW IDer

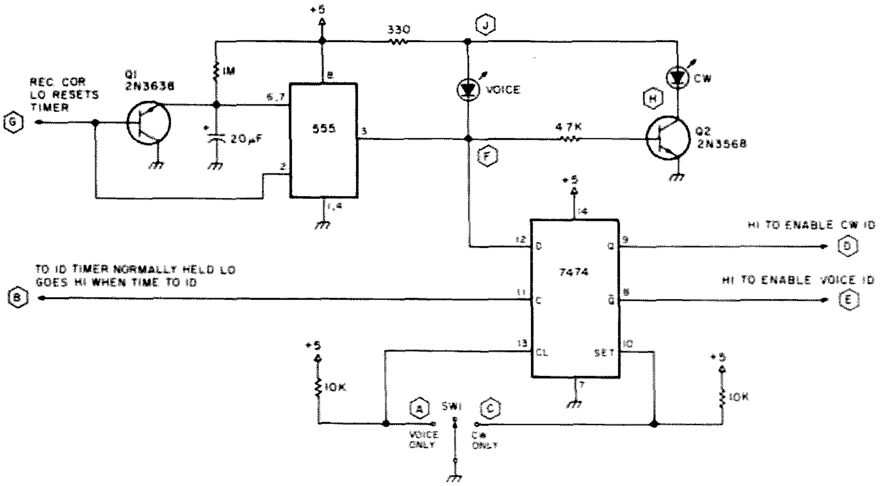

Fig. 1. Dual-ID logic schematic diagram.

which causes the ID to be given in CW only. When the repeater is not in use, when it is kerchunked, or when the last ID after a series of transmissions is given, the circuit will enable the voice IDer.

Operation

Referring to Fig. 1, the 555 timer chip and Q1 are set up as a retriggerable monostable. The 7474 is a dual-D flip-flop. In operation, point A is connected to the repeater COR line at a point that is normally high and goes low when a signal is received. If this is not possible (i.e., the only point easily accessible is a point which is normally low and goes high when a signal is received), a transistor or IC inverter can be used between point A and the base of Q1 and pin 2 of the 555 timer to give you the necessary inversion. Every time a signal is received, the 20 uF timing capacitor is discharged by Q1 and the 555 is reset. During this time, the 555's output (pin 3) goes high and will stay there for 20 seconds unless retriggered. Every time the receiver's COR indicates a received signal, the 555 is reset and retriggered for 20 more seconds. This high is applied to the base of Q2 through a limiting resistor making its collector go low. This lights the "CW" LED to let you know that this ID will come up next. The "voice" LED on pin 3 of the 555 will light only when it times out. This occurs only after about 20 seconds of repeater inactivity.

The information on pin 3 of the 555 is also presented to the D input of the 7474 flip-flop. The C (clock) input of the 7474 is connected to your repeater ID timer at a point which is normally low and goes high when it's time to ID. Again, if this is not possible or inconvenient, an inverter will have to be used to provide the necessary inversion between the repeater timer and point B.

The 7474 works as follows: The info presented at the D input goes on to the Q output whenever the clock changes from low to high. The only time the output can change is when the clock goes positive. Changes on the D input are not passed on if the clock is *held* high or low. Information on the D input can be changed at any time. It is only its value at the instant of the positive clock edge (time to ID) that matters. This is what is entered into the flip-flop.

So, when it becomes time to ID, point B should go high. At this instant, the flip-flop checks its D input. If it is low (the 555 has timed out because of no repeater activity in the last 20 seconds), the low is passed on to the Q output and the Q output goes high enabling the voice ID. If your voice ID requires a low to enable, an inverter can be used after the Q output or the $\overline{Q}$ output can be used to enable the voice ID and the Q output for the CW ID.

The last feature of this ID selector is the use of S1, an SPDT switch with a center off position. With the switch in the off position, ID selection is completely automatic as described above. However, when put in the position where the clear input (pin 13) is grounded, the Q output goes low and the $\overline{Q}$ output goes high and they both stay that way as long as the switch is in that position for a voice-only ID. Conversely, when in the position where pin 10 (set) is grounded, the flip-flop immediately goes into the state with Q high and $\overline{Q}$ low. This gives you a CW-only ID. This becomes very handy if it is necessary to remove either of the IDers for maintenance.

This ID selector will add a bit of "intelligence" and courtesy to your repeater's automatic operation and provide variety and relief from monotony to the ops who monitor your repeater consistently.

I'll be happy to help with any questions you may have regarding connection to your repeater if you will supply the necessary information and include an SASE.■

Adam-12 Revisited

—a scanner unscrambler

This simple circuit will decode the most common scramblers used, and is small enough to fit inside hand-held units.

After buying a new VHF high-low scanner and adding all the necessary options such as crystals, flexible antenna, and rechargeable batteries, I found that it was still lacking one useful option, an unscrambler. Many police departments use a scrambler on some transmissions for one reason or another.

Although there are several schemes for scrambling or encoding audio, by far the most common method is to feed the audio signal along with a carrier into a balanced modulator before transmission. Typically, a 2-3.5 kHz carrier is injected along with the audio, producing a DSB signal centered about the carrier frequency. This signal then modulates the transmitter in the normal manner.

When a scanner that is not equipped with a demodulator like the one at the transmitter receives the scrambled signal, it produces the same sort of garbled (and unintelligible) audio you hear from an AM receiver tuned to a DSB or SSB signal. The fact that I could not receive the scrambled transmissions was enough to prompt me to construct a circuit to recover the audio. I would like to remind anyone who builds one of these decoders, that, as with any other information you might obtain over your scanner, you cannot divulge the content of the transmissions.

The Circuit

I designed the circuit with the following conditions in mind:

1. The circuit must operate on the scanner's 6-volt battery supply.
2. The circuit must fit in the scanner with no external components.
3. The change from normal to decode operation must be simple and quick.

The final demodulator uses a Signetics N5596 balanced modulator/demodulator. The pin designations in Fig. 1 refer to the 14-pin DIP package. The National Semiconductor LM1496 or an HEP6050G is also usable with no circuit modifications, but the pinouts are different. The carrier signal is supplied by IC2, a 555 timer. Potentiometer R1 is used to balance the demodulator (null out the carrier), with no audio input to the IC. R2 adjusts the frequency of

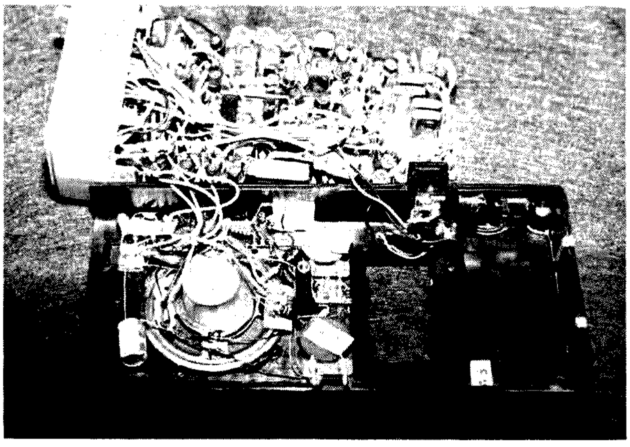

Photo A. View of the inside of the Pro-6 scanner with the decoder installed. Major components are secured to the case with glue.

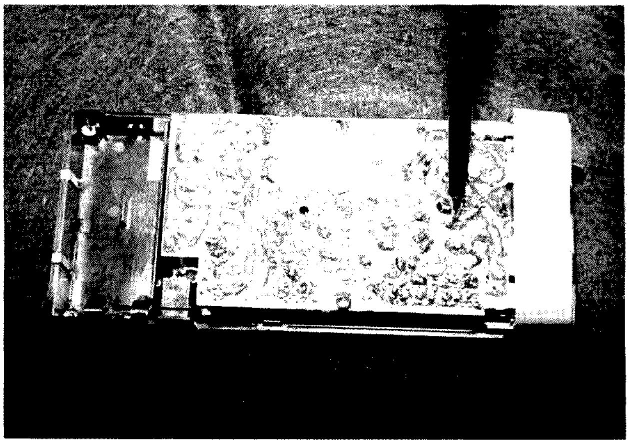

Photo B. View of the foil side of the Pro-6 PC board. The pen points to the point on the board where the volume control wire is disconnected and the decoder input and outputs are inserted.

the carrier generator. R2 must be set so that the frequency of the carrier matches the frequency of the carrier that was introduced at the transmitter. C1 must be selected to give the proper range of carrier frequencies in your use. Since most systems use a carrier frequency of from 2.0-3.5 kHz, C1 = .1 uF is a good choice in most cases (see Table 1). Use a good quality 5% capacitor for C1, as it basically determines the stability of the carrier generator.

Some systems use more than one carrier frequency. Usually these will be designated as Code 1, Code 2, Code Black, Code Yellow, etc. If this is the case in your area, you can add more than one R2 pot, as shown in Fig. 1. A slide switch can then select the proper frequency. If only one frequency is used, S2 may be eliminated, with pin 5 of the 555 connected directly to the wiper terminal of R2. S1 turns the demodulator on and off. I used one of the channel lockout switches on my scanner for S1 and thus did not have to mount any extra switches on the radio. Any general-purpose silicon NPN transistor will work for Q1. The audio input to the demodulator should be about 100 mV rms. This is available at the input to the volume control of most scanners.

Construction

My scanner is a Realistic Pro-6 VHF high-low by Radio Shack, so the photographs and details of the text apply to this particular radio. The circuit itself will work with any scanner or monitor, but the component placement may have to be modified due to space considerations.

I originally planned to build the demodulator on a small printed circuit, but, after seeing how little space was available in the scanner, I had to resort to the less elegant point-to-point wiring method. Owners of the Pro-6 can see where to mount the major components by referring to Photo A.

To disassemble the scanner, remove the two screws at the bottom of the radio just below the battery pack. Now remove the back by squeezing the sides of the front half of the case about 3 inches from the bottom of the case. Once you have removed the back, take out the one screw in the middle of the printed circuit board and remove the front half of the case.

All parts of the demodulator mount in the front half of the case. The ICs are mounted by turning them upside down and securing them with a drop of glue. Be sure to identify lead number one on each IC before gluing it down. The ICs will be hard to remove once glued down, so I strongly suggest that you first construct the circuit on a protoboard if you have one.

Trimpots R1 and R2 should be mounted so that they can be adjusted with the scanner operating. I drilled out two of the "fake" holes in my scanner and mounted the pots behind them, so I could adjust them once the scanner

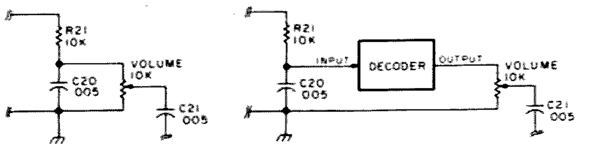

Fig. 2. Details of decoder input and output connections to the Pro-6 scanner. Other brands of scanners will have similar configurations.

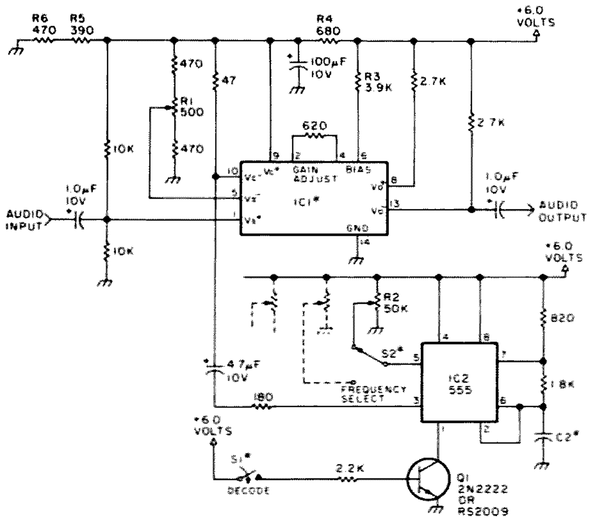

*Fig. 1. Unscrambler schematic. IC1—N5596 14-pin DIP; LM 1496 or HEP6050G also suitable; see text. IC2—555 timer, 8-pin DIP. Q1—2N2222 or RS2009, NPN silicon general purpose. All fixed resistors ¼ W, 10%. * = see text.*

was assembled. After operating the scanner for a few weeks, I found the circuit to be stable enough so that adjusting the pots again was not necessary. Make the needed tie points by gluing small pieces of printed circuit board to the case. Be careful to mount the parts so that they do not interfere with the reassembly of the case.

I used one of the channel lockout switches for S1. If you elect to do the same, refer to Fig. 3.

Testing and Adjustment

Once the circuit is complete, but before connecting the audio input and output to the scanner, you should balance the demodulator. Connect an oscilloscope or high-impedance headphones to the output of the circuit, apply power, and turn the decode switch on. You should have a square wave on the oscilloscope or a tone on the headphones. Adjust R1 to null the carrier output.

If all was well in the previous step, you are ready to connect the demodulator. Unsolder the wire on the PC board going to the volume control. This is a green wire on the Pro-6. See Photo B for the proper location. Solder this wire to the output of the demodulator. Now connect a short wire from the point

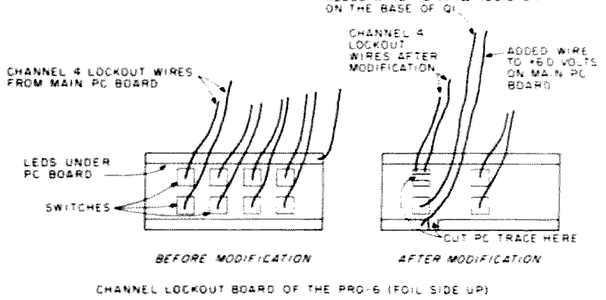

Fig. 3. Modifications to the channel lockout board of the Pro-6 to allow the channel 4 switch to be used as S1 of the decoder. Channel 4 of the scanner will always be active after the modification.

on the PC board where you removed the previous wire to the input of the demodulator.

When S1 is in the off position, the scanner will work normally. When you hear a scrambled message, turn the demodulator on and adjust R2 for a readable output. If you cannot get a low enough frequency for your needs, simply add some capacitance to C1, as in Table 1.

Comments and Conclusions

In operation, the decoder has been totally stable and performed well. When the decoder is switched off, it draws about 3 mA. When it is switched on, it typically draws 15 mA and has little effect on battery life.

If your scanner operates on a higher voltage, scale up R4, R5, and R6 by the % voltage increase (approximately) that you have above 6 volts; also adjust R3 to give 1.0 mA current into pin 6.

I will be glad to answer any questions if an SASE is enclosed. ■

Value of C1 (uF)	Carrier frequencies obtained (Hz) Lowest	Center	Highest
0.10	1650	3500	6000
0.15	1000	2500	4000
0.20	800	2000	3000

Table 1. Selection guide for C1. Lowest, highest, and center frequencies of each range obtainable by adjusting R2 are given.

LETTERS

from page 11

reason, the BS that the ARRL has dished out to Mary has frustrated me.

Mary, as far as I know, started having trouble when she ran against W7PGY in the last director election. I don't know that Thurston was responsible for the mudslinging that Mary got, but he certainly benefited the most from it. If enough people had read between the lines, just maybe the election would have come out differently.

When the election for SCM came up, two people were nominated: W7QGP and W7IEU. The results of the election are obvious; Mary was disqualified. I have proof that Mary was disqualified after the fact. It seems that the people charged with looking after our best interests took it upon themselves to change the rules or by-laws so as to disqualify W7QGP; this caused W7IEU to win by acclamation.

After the fiasco of the SCM election, Mary filed suit in the court system out here. This brings me to the next point of interest.

A few months ago, notice was given in *QST* that elections were to be held for Northwest Division Director and Vice-Director. When after the deadline for nomination petitions had expired and only W7QGP and W7PGY had been nominated, the election was set aside until the litigation concerning the SCM election was settled. Meanwhile, the executive board (minus W7PGY) voted to have W7PGY, his highness and not so exalted ruler of the Northwest Division, Mr. Thurston, act as a caretaker director until such time as the aforementioned litigation is resolved. So far, the litigation has gone on for almost 2 years now, and, by the looks of it, probably a couple more years.

Well, fellow members of the Northwest Division, it seems we are enslaved to the junta in Newington under direct command of Field Marshal Thurston. Heil! Heil! Long live the regime!!

I must close for now and pay homage to his excellency, W7PGY, on my knees bowing down towards Seattle.

Phillip J. Kelly, Sr. WA7DKA
Vancouver WA

P.S. I have remained a member of the ARRL for the sole reason that if any reasonable facsimile of a fair election is run, I want to be able to vote W7PGY out.

HR-13015

You are generally on top of things coming out of Washington which affect amateur radio, so I am somewhat surprised that I've read nothing in *73* (or in any other amateur publication) about a bill currently in Congress which could have an impact every bit as great as WARC. The bill is HR-13015, which was introduced last June by Lionel Van Deerlin (D-Cal.) and Lou Frey (R-Fla.). It is titled "The Communications Act of 1978" and is now moving through the Committee on Interstate and Foreign Commerce, of which Van Deerlin is chairman.

The Van Deerlin-Frey bill has received a great deal of press among broadcasters because of the sweeping changes it would make in regulation of the radio/television broadcast industry. The point is to deregulate the broadcasters, and let free enterprise take its course. The bill also seeks to break up the Ma Bell/AT&T monopoly.

But HR-13015 would also affect amateurs. Amateur radio is not specifically mentioned in the bill, and that in itself is disturbing, since it would affect us so directly. The act, if passed, would repeal the Communications Act of 1934 entirely. It would eliminate the FCC, setting up a 5-member Communications Regulatory Commission in its place. There would also be an independent, policy-making arm of the executive branch known as the National Telecommunications Agency. The duties of the Commission and the Agency, as outlined in the bill, are primarily concerned with broadcasting, although the Commission would also regulate some "non-broadcast services" such as common carriers. Again, the Amateur Service is not mentioned. (Do they know something we don't?)

One interesting change in the bill would be the charging of license fees according to the amount of spectrum allocated. A TV broadcaster would be charged for his 6 MHz, while an AM broadcast station would only have to pay for 10 kHz, etc. In reading the bill, I can't determine if this same system would be applied to the "non-broadcast services," but can you imagine what a ham license would cost if it were? Our 420-450 MHz band alone would cost the same as five TV broadcast permits!

I think this legislation bears looking into by amateurs, and I'll be interested in reading further comments on it.

DELETE THE DOWNLINK

I would like to express my opinion about the OSCAR-type ham satellites with downlinks into 10 meters now that the band is fully open for worldwide communications direct. It would seem that the time has come to turn off the OSCAR 10 meter downlink.

The reason for my position is that even 100 kHz is a lot to take out of the usable spectrum. Now that the Soviets have put up their two satellites, this has increased to 200 kHz, which seems to be forbidden territory for those wishing to make direct contacts.

The pass time over any given area may be good for only 15 to 20 minutes of acquisition, but now that near-normal direct skip prevails over such a wide area in all directions, it means that interference chances are many times greater because of the wider area a direct skip signal may cover.

There are several other factors that make OSCAR-type satellites unethical at this time, one being the large number of Civil Emergency Preparedness Stations which have been established on these frequencies since shortly after WWII, another being the many QRP stations which have been squeezed out of the lower portions of the band by high-powered activities there.

It is unfortunate that the Soviets chose to make their major output in the 10 meter band at this time of increasing good skip conditions.

I have suggested to AMSAT that if they lead the way now by

Digital RTTY Is Simple

—easy as 01, 10, 11

Copy wide- or narrow-shift RTTY with this digital converter.

Lately, I have become interested in getting on a local 2 meter repeater and working some radioteletype (RTTY). I have a 2 meter rig and an old Teletype™ unit, but getting the audio from the speaker to the Teletype print magnet in a language it could understand was a problem. While doing some research and trying to decide on one of the inexpensive RTTY converters described in different magazine articles, I thought how nice it would be to connect my digital frequency counter to the speaker of my receiver, display the frequency, and tell my Teletype unit, "When this display changes from 2125 to 2295, disconnect the power from the print magnet." Of course, there is no way that my counter was going to keep up with the rapid frequency shifts of radioteletype, but the idea stuck with me. It resulted in an inexpensive RTTY converter that is easy to build and operate.

The main element in getting a good copy on a Teletype is to turn the print magnet off and on at a

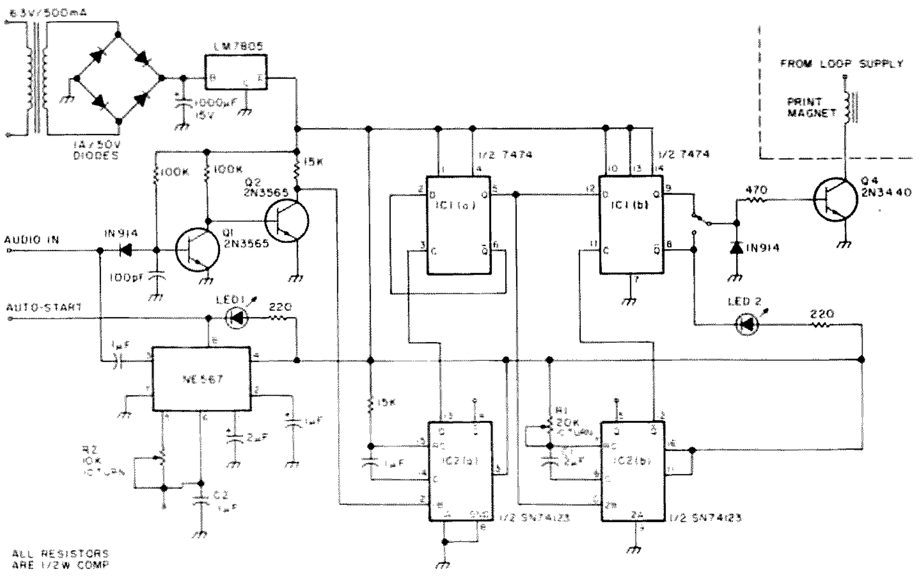

Fig. 1.

precise timing rate. A "mark" turns the magnet on; a "space" turns it off. At 60 wpm, the number of marks and/or spaces that occur during a 163 ms period tells the machine which character to print. A "space" is not the character you get when you hit the space bar, but it signifies that no current is being drawn by the loop.

I knew the first thing I needed was a square audio wave to clock the digital circuitry. After a few hours of building different squaring circuits, Q1, Q2 (Fig. 1) turned out to be the one with the best waveshape with the minimum output voltage required to obtain a square wave output.

Rather than use a method of counting the audio frequency, I decided that it would be easier and require less parts to measure the time between cycles. In order to do this, the first cycle has to turn on a timer and the next one turns it off. I used the popular divide-by-2 method using the SN7474 dual D-type flip-flop. The SN7474 can be used as a place to store data, also. When the SN7474 is clocked by a low-to-high voltage transition at its clock input, the voltage value of its data input (D) is moved to the "Q" output. The "$\overline{Q}$" output is always the opposite of "Q". Data is referred to as a "1" being the higher voltage (4 V typically) and "0" being the lower voltage (.2 V typically). If the "$\overline{Q}$" is connected to the "D" input, the "Q" output will be high on every other clock cycle because "$\overline{Q}$" is always the opposite of "Q". This divides the clock frequency by two.

Now that "Q" is a "1" for one complete cycle of the input frequency, a reference pulse is needed to compare this time with. The SN74123 provides this pulse. The output of the SN74123 can be triggered and the output pulse width can be set by an RC network. It also has a "$\overline{Q}$" opposite of "Q".

There are two one-shots in an SN74123. One of them is used to help square the audio input. The RC time constant of this half is set for approximately 150 µs.

The input circuit was designed to work with the speaker connected to the audio output used. Only 300 mV p-p is required to get a square audio wave out.

The audio input is squared and conditioned by Q1, Q2, and IC2(A). The "Q" output of IC2(A) is connected to the clock input of IC1(A). IC1(A) divides the input frequency by two. The high logic level at the "Q" of IC1(A) is now equal in time to the time it takes the input frequency to complete one cycle. With 2000 Hz at the input, the "Q" output of IC1(A) will be high for 500 µs; at 2170 Hz, "Q" will be high for 460.8 µs.

When "Q" of IC1(A) goes high, this clocks IC2(B), causing "$\overline{Q}$" of IC2(B) to go low at the same time. The output pulse length of IC2(B) can be adjusted to a desired length by R1.

If the output pulse length of IC2(B) is set to 480 µs and input frequencies of 2000 Hz for mark and 2170 Hz for space are used, the "$\overline{Q}$" output of IC2(B) will be low for 480 µs and will go high while "Q" of IC1(A), on mark, is still high. But it will go high after "Q" of IC1(A), on space, goes low. The low-to-high transition of "$\overline{Q}$", IC2(B), clocks the "Q" of IC1(A) into "Q" of IC1(B). A "1" will always be clocked in for a mark and a "0" will be clocked in for a space, as shown by Fig. 2.

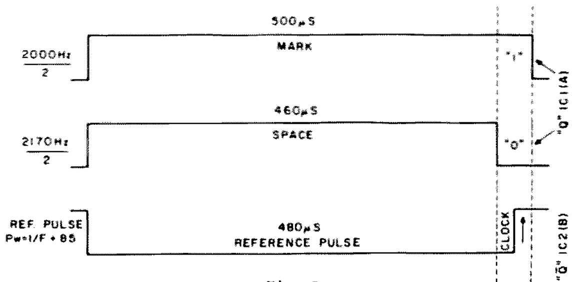

Fig. 2.

The "Q" or "$\overline{Q}$" of IC1(B) can be selected for upshift (Q) or downshift ($\overline{Q}$) and used to drive the loop switch, Q4. This output could also be used to drive a UART.

The converter should be set to convert narrow shift. Then it will decode both wide and narrow shifts.

To adjust the converter, apply a 300-500 mV p-p audio signal at the desired mark frequency to the audio input. Connect a scope to "Q" of IC1(A), pin 5. This output should be a clean square wave at half the input frequency. Disconnect the scope and connect it to "$\overline{Q}$" of IC2(B), pin 12. Adjust R1 until the low-level pulse width is equal to Pw. Pw = 1/F + 85, where Pw is the pulse width in seconds and F is the input mark frequency.

Disconnect the scope and connect it to the "Q" output of IC1(B). This output should be high. Adjust the input to the frequency of the space signal (mark frequency + 170 Hz for narrow shift). "Q" should be low. Shift the audio frequency from mark to space and back. The "Q" output should now shift with the input; 1 equals mark, 0 equals space. If the PLL tuning indicator is used, adjust the audio input to the mark frequency and then adjust R2 until LED1 turns on. Adjust R2 and find the center of the bandwidth of the PLL. The converter is now ready to convert up-, down-, narrow-, and wide-shift radioteletype.

Tuning is done by adjusting the bfo of the receiver and is not difficult. If the converter is to be used on 2 meters, it should be aligned for the standard audio frequencies used in your area. LED2 will blink as a shift in frequency occurs and, if the PLL circuit is used, will also "unlock" randomly, especially on wide shift.

Some other input circuits could be used, such as an FET or Schmitt trigger, and some noise limiters and audio filters added, but they are not at all necessary to get a good copy from a good signal.

I built the converter with VHF RTTY in mind, but have used it to receive Teletype on the HF bands where noise and fading did cause problems. As long as the audio was decent and noise was at a minimum, the converter didn't miss a character.

The phase locked loop circuit using the NE567 was built as an autostart circuit, but makes a great aid for tuning.

For more information on the NE567 PLL, see the November, 1977, issue of *73 Magazine*. For more information on one-shots, see the February, 1977, issue of *73*. If you need to do some reading about radioteletype in general, read the September, 1977, issue of *73*.

I etched a 3" x 5" circuit board and had plenty of room on the board for the power supply. A breadboard or hand-wired circuit will work just as well.

The converter was housed in a Radio Shack cabinet no. 270-252. The LEDs are Radio Shack no. 276-026. ■

Take the Pledge

—a no-compromise console

This simple approach to building your final equipment features two-tiered, sloped construction.

Following a long history of futile attempts at misusing desks, adding tabletop extenders, building shelves, and the like, I finally decided upon the pictured design for my amateur radio equipment console. Photo A illustrates the unit, complete with the following features:

1. a sloped top to aim the upper equipment down;
2. a sloped bottom to aim the lower equipment up;
3. a storage shelf for books, logs, parts, meters, etc.;
4. an inexpensive woodgrain contact paper finish; and
5. portability to sit atop any existing table or desk.

After estimating the costs to have it built from particle board covered with Formica™ by an acquaintance who is a part-time cabinet maker ($350), or simply to purchase a metal workbench of similar style but less capacity ($150), I made myself an offer that I couldn't refuse: "Do it yourself, but take your time and do it right, and the XYL will be on your side forever!"

Photo A.

The total construction costs will be variable, mostly dependent upon your current supply of scrap lumber and hardware as follows:

1. two aluminum angles @ $4.95
2. four T-braces @ 50¢
3. twenty feet woodgrain contact paper @ 59¢
4. screws, nails, glue, etc., for $5.00
5. optional electrical outlets and lamp(s)
6. one and one-half sheets of plywood (4' x 8' x ½")

Begin to get the overall construction details clear in your mind by referring to Photo B and Fig. 1. The unit is four feet wide, by all the dimensions shown in Fig. 1. The dotted lines represent an internal barrier to keep things from getting lost in the very least accessible nooks and crannies. The shaded areas represent the internal supports needed for strength and stability.

I stress the use of plywood instead of particle board because of its lighter weight and ease of maneuverability, its ability to accept screws and nails without fracturing, and its esthetic wood grain if you elect to give it a natural wood finish instead of using the contact paper option.

If you are not an experienced cabinetmaker, I recommend that you acquire and read the following literature before commencing the actual construction:

"How to Buy Plywood," *Popular Science*, Feb., 1977, page 122; "How to Work With Plywood," *Popular Science*, Mar., 1977, page 124; *NBS Voluntary Product Standard PS51-71, Hardwood and Decorative Plywood*, SD Catalog number C13.20/2:51-71, Government Printing Office, Washington DC 20402.

The first step towards construction is to precut the following sizes of plywood. They can be cut most efficiently according to the diagrams in Fig. 2: 48" x 30" bottom plate, 48" x 18" bottom shelf, 48" x 12¾" bottom slope (20° cut), 48" x 24" top plate, 48 x 11¾" top shelf, 48" x 11" top slope (20° cut).

The slope pieces require angled edges if you don't want to use up all of your Plastic Wood™! The specified lengths include the extended edges of those angled cuts.

Next, precut the internal supports and sides from plywood, or from one-inch pine (the latter is recommended if it is available): 30" x 4½" bottom sides (two pieces), 22" x 5" top sides (two pieces), 6" x 4½" internal support (for bottom), 6" x 5" internal support (for top).

Refer to the details illustrated in Fig. 1 to make the angle of slope on the side pieces, and the 20° cut angle on the slope pieces.

Then, precut the miscellaneous parts as follows: 48" x 1" bottom rear ledge, 48" x 1¾" top front ledge, 47" x 4½" internal barrier (for the bottom). This internal barrier can be made of any material from plywood to plasterboard because it doesn't have to support any weight, it is not usually visible, and you're trying to build this console for next to nothing, aren't you?

Finally, you can go to your local building supply center to acquire the following items:

1. four-penny finishing nails (½ pound)
2. white glue (large bottle)
3. four 3-inch T-braces with mounting screws
4. two 8-foot lengths of ¾" angles of 1/8-inch aluminum
5. six #8 x 1" aluminum screws, bevel-head
6. six #6 x ½" aluminum screws, flat-head
7. miscellaneous electrical fixtures if you aren't reusing whatever you were using before you decided to build this project (I used two outlet strips with six outlets each, one for the top and one for the bottom); you may also want to install a small fluorescent lamp fixture

You are now ready to assemble the console. Remember to use an abundant application of glue at every point of contact. Then remember to wipe away the excess glue after the nails have been driven and countersunk. Since the glue is typically water soluable, all you need is a wet rag for this cleanup procedure.

Begin by building the structural portion of the top and bottom, by referring to Fig. 3. Attach the sides to the top and bottom plates by seating all pieces *atop the plates.* Then attach the internal supports in a similar manner, centered left to right, but secured three inches from the open edge. Now attach the internal barrier for the bottom section; its back side should be flush with the beginning of the downslope cut of the side pieces.

Complete the main sections by affixing the shelf pieces to the top and bottom. As you may have figured out by now, I've saved the best for last. The angle cuts of the slope pieces may have to be "fine tuned" for an acceptable fit due to your manufacturing tolerances. The best way to implement those adjustments is by eyeballing the fit and adjusting the angle of the cut until you're satisfied with your own craftsmanship. Now apply the front and rear ledges, and all the hard work is over. The tedious work now begins!

Take a few moments to smooth the edges and joints, to countersink all the nails, and to fill and sand all those countersunk nail holes, joint gaps, and surface imperfections. If it doesn't look and feel smooth at this point, you'll be disappointed later, especially if you opt for a natural finish.

It is now time to apply the finish of your choice. I decided to use contact paper because the scrap lumber I used didn't consist of all unfinished lumber. Also, I wanted to match the finish of the low-boy filing cabinet, as well as other items already in the shack. Modern adhesives work well on a clean surface, so be sure you have removed all the sawdust possible with a tacky cloth before you start to apply the contact paper.

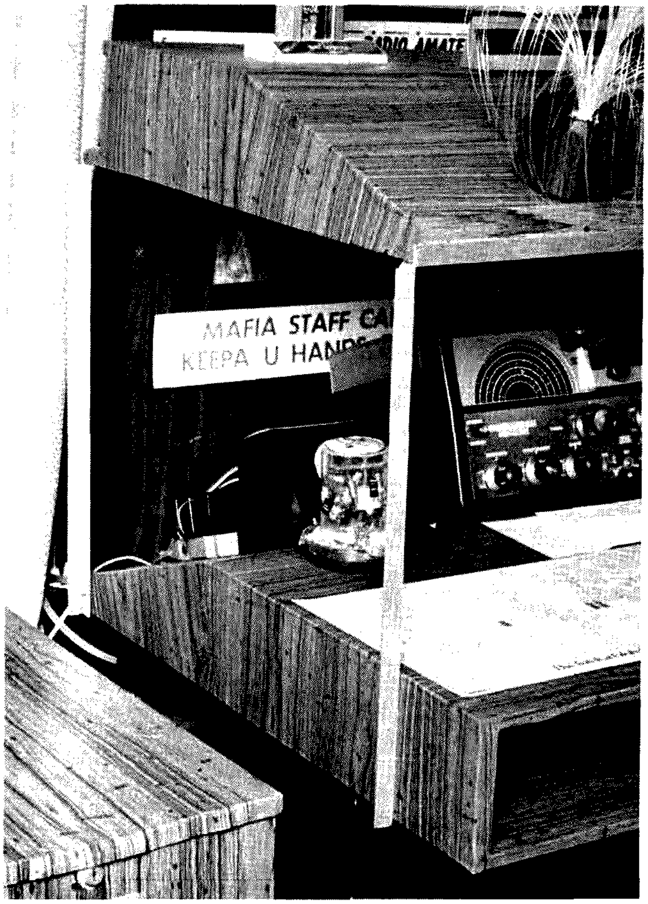

Photo B.

As alternatives, however, you may choose to stain it, then finish it with varnish or shellac, or to paint it, or to apply a veneer or a laminate, depending upon your needs, skills, and finances.

Once that finish is com-

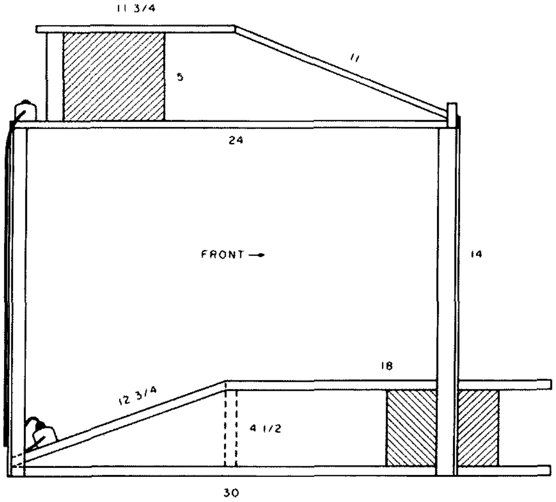

Fig. 1.

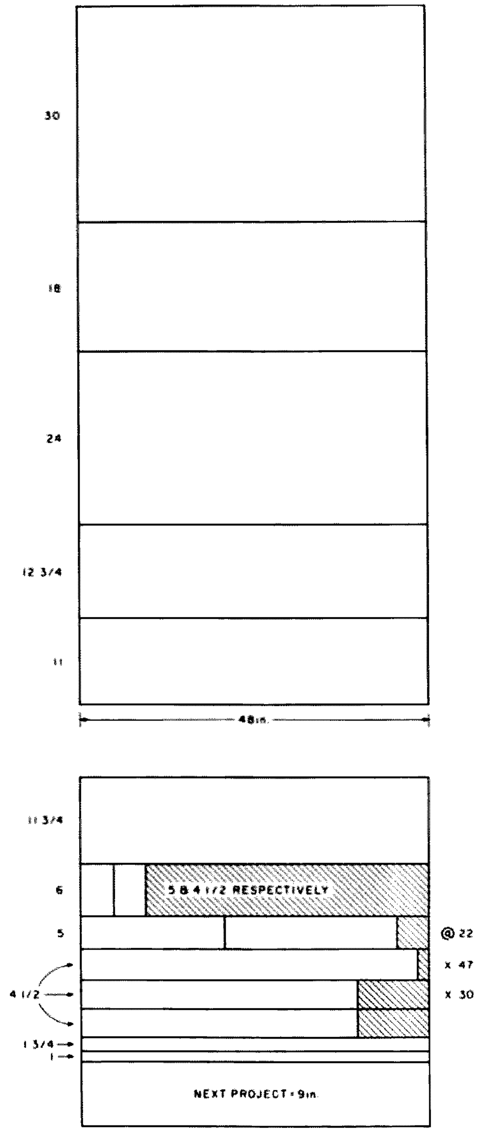

Fig. 2.

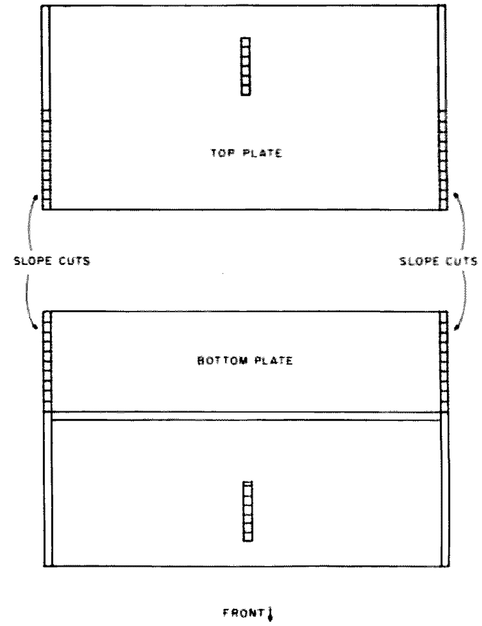

Fig. 3.

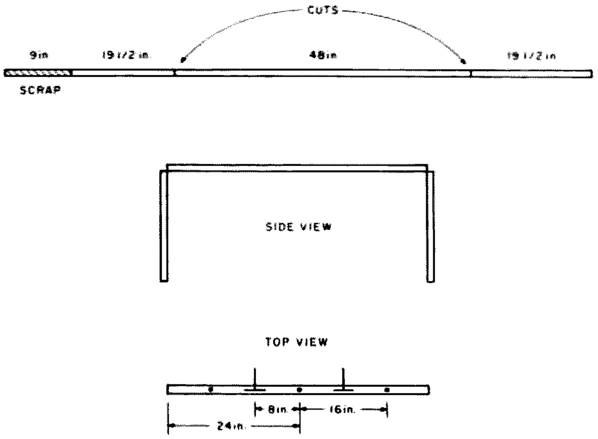

Fig. 4.

plete, the legs can be constructed. The top is supported by, and separated from, the bottom by two aluminum angles reinforced by four T-braces. To fabricate the aluminum supports, first make two cuts on the same edge of both pieces of angle as illustrated in Fig. 4, then scrap the nine-inch cutoff. At the point of each cut, secure the uncut side in a vise (or between two pieces of scrap lumber held together by two C-clamps). Heat the area thoroughly with a propane torch, then slowly and carefully bend the metal to form a right angle, taking special care not to crack the metal on the bend. On each piece of metal, the edges of the two cuts that are now opened 90° should be filed smooth, as should the newly created corners. Drill three holes in the forty-eight inch section, one centered with the other two located sixteen inches each side of center. Countersink these holes to accommodate your flat-head screws; they will hold the top section to the angle pieces.

Turn the top section upside down to drill pilot holes for these flat-head screws and for the T-braces. Secure the aluminum supports with the flat-head screws, then install the T-braces for additional strength, centered eight inches each side of center, as illustrated in Fig. 4.

Right side up, this assembly will wobble easily on these legs, but once secured to the bottom with three screws on each side, it will be sturdy enough to support a human being, let alone your kilowatt amplifier! That task is easily accomplished with two bevel-head screws in each front leg, and one in each rear leg.

Install your outlets at the rear of each section, and secure the feeder cable for the top strip to the back of a rear leg to hide it. If you opted for a lamp, install it now, too.

Finally, sucker an accomplice ... er, ahem .. convince an able-bodied acquaintance to help you carry your creation from the woodshop to the ham shack, and lift it atop your old desk or table. If you used the contact paper finish, remember to be careful not to snag or to tear the plastic when you finally move in, connect, and check out your equipment. Now you may call in the boss for her approval.

Say, have you given any thought to building another console for your test equipment at the service bench? ■

Two Meter Tone Alert

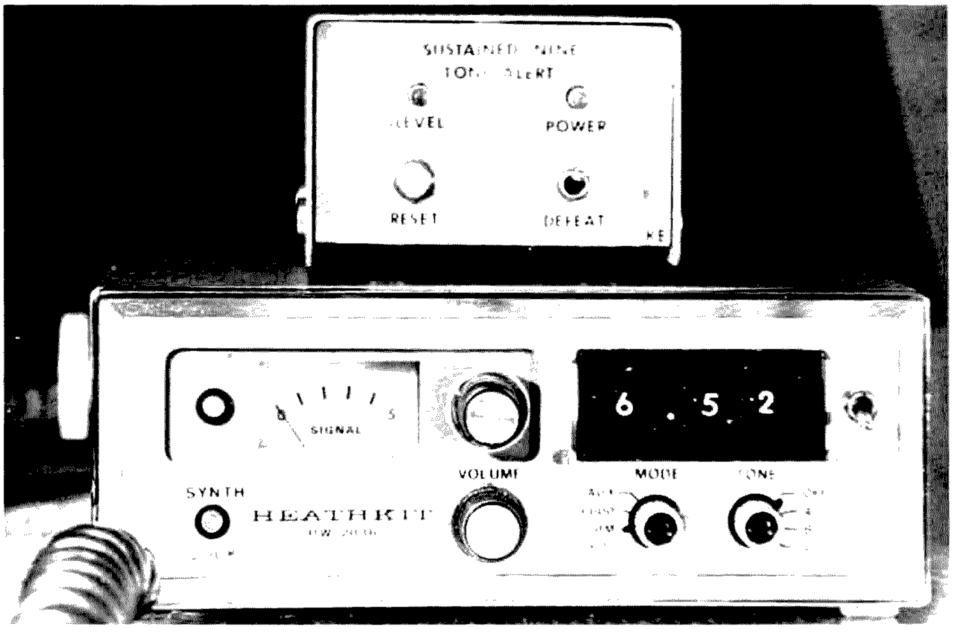
—keep everyone on call

This system can provide emergency help at the dial of a "9".

Rodney A. Kreuter WA3ENK
R.D. #1, Box 27G
New Stanton PA 15672

Here in southwestern Pennsylvania, we have had our share of emergencies lately. The Johnstown flood and two hard winters have kept the local two meter repeaters from gathering dust. However, many hams, myself included, do not monitor these repeaters as much as we should because, many times, we are busy doing something and don't want to be interrupted by local rag chewing or routine traffic. Of course, I'm sure that there isn't a ham in our area who wouldn't drop whatever he was doing and man his station if he was needed.

The morning after Frank WB3HIY had found some stranded motorists in need of first aid for frostbite, Larry WA3YIR and I were discussing the use of the local repeater during times of emergency. Larry, who is the emergency coordinator for Westmoreland County, suggested that it would be very useful to have a type of tone alert similar to those used by fire companies and ambulance services. Two meters is ideal for this, with its local coverage and fixed frequencies for repeaters. Since a great many hams now have touchtone™ pads for autopatch, it wouldn't be very difficult to use these to activate two meter monitors. All a person needs to do is access a repeater and touchtone in a certain code.



The system ready for operation.

Since a fair number of repeaters now have autopatch, the tone alert decoders would have to be designed to ignore the tones used in making phone calls. The easiest and most reliable system of accomplishing this was to delay the output of the decoders so that the tones would have to be present for at least 4-6 seconds to trip the monitors. This doesn't mean that it can never trip during routine autopatch use, but anyone who holds a key down for that long needs help anyway.

The number 911 is the most often used telephone number for emergency service, so we decided to make our tone alert system activate when the number

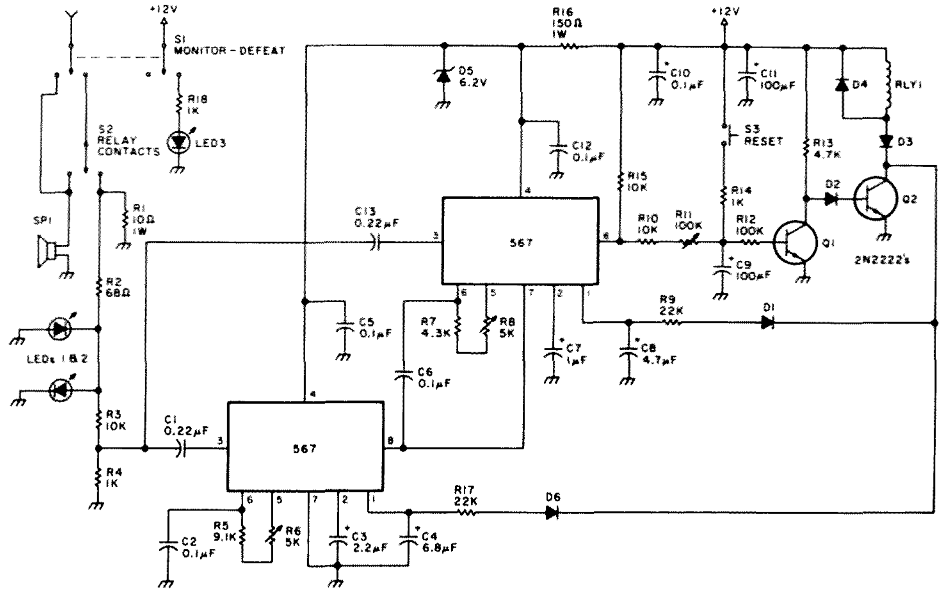


Fig. 1. S1 — monitor, defeat; S2 — relay contacts; S3 — reset.

9 is transmitted for longer than about 8 seconds.

Circuit Operation

In the monitor mode, audio is fed from the receiver to the 10-Ohm resistor, R1. R1 acts as a load for the audio amplifier and should match its impedance. If you don't know what the load impedance should be, use 10 Ohms.

The volume control on the receiver should be adjusted so that the LEDs light dimly when a set of tones is received. Since most LEDs have a turn-on threshold of about 1.7 volts, the audio voltage will be about 1.2 volts rms when the LEDs light. Resistors R3 and R4 divide this voltage down to about 100 mV, which is a voltage that the 567s seem to be happy with.

One more note on the volume control setting on the receiver: With the receiver pumping out 1.2 volts rms, the audio power delivered to the speaker when the tone alert activates will be about 200 mW. This is plenty for my ears. If your ears are different, do this:

1) Choose the audio power that you want;

2) Calculate the rms voltage for this power rating from $E = \sqrt{P*8}$ (assuming 8-Ohm speakers);

3) The new R2 = [(1.4*E) − 1.7]/0.01 (R2 in Ohms); and

4) If you choose to use less than 200 mW, forget the above three steps. The LEDs won't light, so leave them out. Instead, adjust the volume controls so that you get 100 mV at the junction of R3 and R4. A scope or VTVM will suffice.

Since the LEDs limit the voltage to 1.7 volts peak, it won't be necessary to change R3 and R4 unless you opt for lower power. If you do want to use less than 200 mV, calculate the new R3 from:

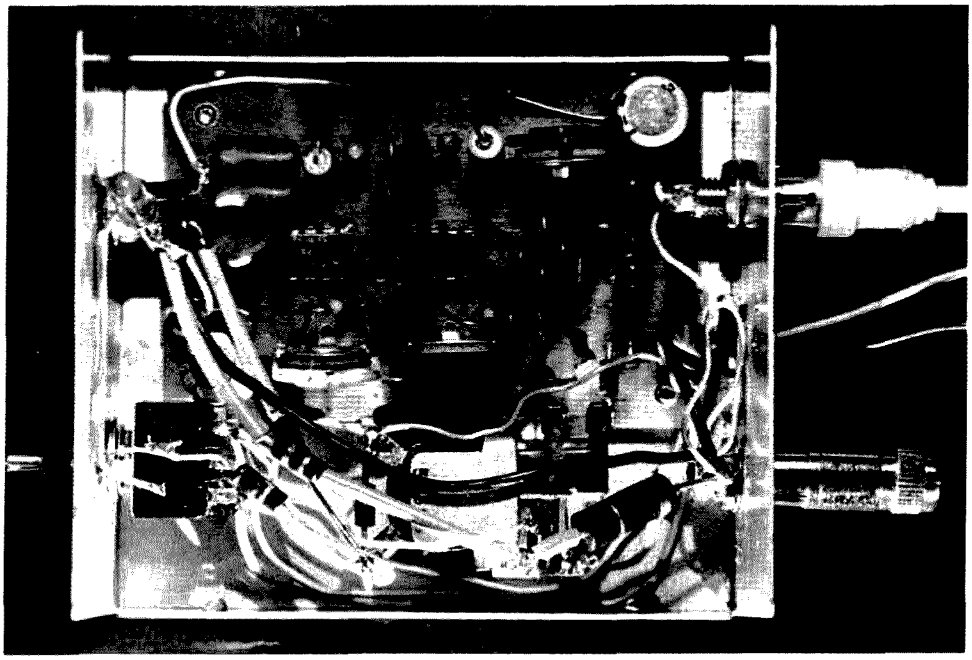
R3 = (10*E) −1
(R3 in k Ohms)

Now that you have 100 mV feeding the 567s, you can proceed to more important matters.

As everyone knows, the tone for the number 9 consists of two tones, 852 and 1477 Hz. The load of IC1 is IC2. Therefore, IC1 is always drawing current from the power supply and "listening" for that 852 Hz tone. IC2, on the other hand, isn't doing anything because IC1 controls its power supply and it won't have any source of current until IC1 "hears" 852 Hz. This saves current and provides the means of producing an output only when both tones are present.

When the tones representing the number 9 are received by the monitor, the output (pin 9) of IC1 saturates (goes from about 5 volts to 0.5 volts). Now IC2 has power and it "listens" for 1477 Hz. If 1477 is present, IC2's output also saturates and energizes the delay circuit, Q1 and Q2.

Capacitors C4 and C7 slow down the action of the tone decoders a little (0.5 to 1 second), but Q1 and Q2 provide most of the time delay. Additional time delay could be obtained by making C4 and



Inside view of the tone alert.

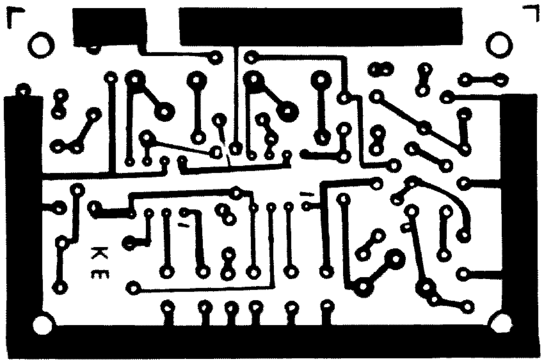


Fig. 2. PC board.

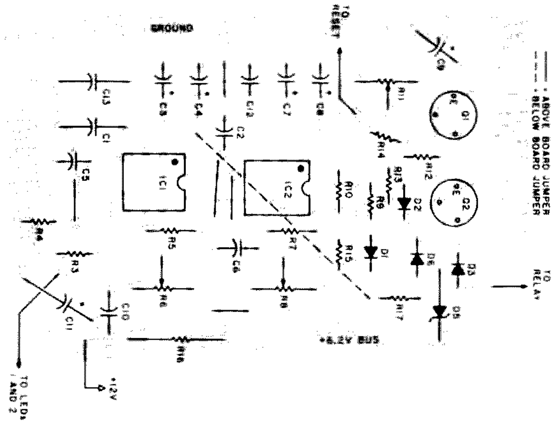

Fig. 3. Component layout.

C7 much larger, but the decoders would be very sluggish and it would be more expensive to do it in that manner.

The time delay operates as follows. Initially, capacitor C8 charges to about 12 volts through resistors R10, R11, and R15. This causes Q1 to turn on and Q2 to turn off. When pin 8 of IC2 goes low, capacitor C8 begins to discharge through R10, R11, and R12. When it has almôst completely discharged, Q1 turns off and Q2 turns on. This pulls in the relay and latches the circuit. Time delay is controlled by R11.

Resistor R9 and diode D1 provide the latching function for IC2. When Q2 finally saturates, pin 1 of IC2 is low. The voltage at pin 1 is then kept low by the diode and resistor. By applying a positive voltage to pin 1, the circuit is reset.

If the tones should end before the time delay times out, as in the case of a routine autopatch, nothing will happen because Q2 never saturates. C8 will be partially discharged, but it will recharge in a few seconds and be ready for an alert.

Construction

The easiest method of construction is to use the artwork in Fig. 2 and make a printed circuit board. This would be especially useful if a club were to photographically produce a lot of boards. Perfboard construction could be used, since the circuit isn't very complex and layout is not critical.

Some components, such as the LEDs, relay, and speaker, were left off the board so that you can use any size components you might have. The relay should not draw any more than 150 mA. Mount the LEDs somewhere where you can see that the device is receiving the proper audio voltage.

A bypass switch (S1) can be used to defeat the tone alert, or you can simply switch to the internal speaker of your rig.

Use the highest quality components that you can afford for this project. This device by its very nature might be called to work for months at a time without any testing. I would suggest that, if your local repeater group has nets every week, the monitors be tested before each net.

Use at least ½-Watt resistors unless otherwise marked. Capacitors should be at least 10-volt unless otherwise marked. Total cost of the tone alert should not be any more than about $15 — junk box to the rescue!

Adjustment

Adjustment is not difficult, but it will take some time, mostly due to the fact that the decoders are a little broad and a little slow to react.

Tune IC1 first. Turn R6 fully counterclockwise. Have someone transmit the tones for the number 9 (simplex, please). Apply power to the board, wait about 15 seconds, and then reset IC2. Adjust the volume on your receiver so that the LEDs just light.

Connect a voltmeter from pin 8 of IC1 to ground. Slowly turn R6 until the voltage falls from 5 volts to about 0.5 volts. Mark this point on the pot. Repeat the tuning with the pot initially in the clockwise position. The final setting of the pot will be midway between these two points. Have your friend pulse his pad — about 2 seconds on, 2 seconds off — and make sure the decoder falls each time.

Now proceed to IC2. Remember that IC1 must

Parts List

C1, C13	0.22 uF	R2	68Ω ½ W
C2, C5, C6, C10, C12	0.1 uF	R3, R10, R15	10k
C3	2.2 uF/16 V	R4, R14, R18	1k
C4	6.8 uF/16 V	R5	9.1k
C7	1 uF/16 V	R6, R8	5k trimpot vertical mount
C8	4.7 uF/16 V	R7	4.3k
C9, C11	100 uF/25 V	R9, R17	22k

D3, D4	1N4001	R13	4.7k
D5	6.2-volt, 1-Watt zener	R16	150Ω 1 Watt
IC1, IC2	567 tone decoders	RLY1	12 volt SPDT relay 150 mA or less (see text)
LED1, LED2	red LEDs	S1	DPDT switch (power-defeat)
LED3	green LED	S2	relay contacts
Q1, Q2	2N2222 or similar	S3	N.O. push-button (reset)
R1	10Ω 1 Watt	SP1	8Ω speaker

be working before IC2 will operate. Perform the same type of adjustment using R8.

After you are certain that the pots are set correctly, epoxy, glue, wax, or nail polish them so that they cannot move. Adjust R11 for the proper amount of time delay. Six or seven seconds is okay.

One warning about the tones you use for adjustment. Be sure that your friend has a good touch-tone pad.

Depending on what type of relay you might have available, you might do more than just switch in a speaker. A flashing light or tone, for example, might be switched in by an extra set of contacts.

Use

It comes to mind that a device such as this could be misused out of existence rather quickly. We are fortunate here in our area that we don't seem to have that problem.

To be really effective, as many hams as possible should know that a group of people in your area have these devices and are monitoring a certain repeater with them. It would be best if at least a few people on each repeater frequency have the tone alerts.

Another possibility that should not be overlooked is that alerts built for other tones could be used as a private line with friends or the XYL. A club could also have its own to alert members to cancellation of meetings or other business that would affect only those people.

Many thanks to Larry WA3YIR for his help with testing and printed circuit artwork.■

MORE GROANING

To K4KI's informative article ("Silence Groaning Refrigerators") in the November, 1978, issue of *73* should be added several additional points to avoid problems he described. In addition to cleaning up bad connections in junction boxes, outlets and switches that show signs of overheating should be replaced. Appliances such as washers, refrigerators, garbage disposals, and air conditioners should be fed by separate circuits directly from the fuse or breaker panel. A common neutral as he describes in his article must be avoided! Balance the current draw on each side of the 220-volt service if possible; for example, if you operate 4 window air conditioners drawing 7 Amps at 117 volts, arrange separate direct wiring to each unit. At the fuse panel, two units should be connected between one of the 220-volt legs and neutral, and the other two between the opposite leg and neutral. If local building regulations do not permit you to work on your wiring in your own home and if you are otherwise not qualified, find a competent electrician.

William W. Muessig K4FD
Falls Church VA

Mr. Muessig does not support his statement about running appliances directly to a fuse box using separate circuits by referencing the specific requirement of any recognized electrical codes. Three-wire systems have been developed for specific technical reasons. They have been in use for many years and are still being installed. As in any electrical power system, poor connections can be hazardous.

As electrical codes are quite complex and differ in various locations, the best thing to do is to check your code and see if your wiring conforms. One of the problems is that older houses may not conform to the latest codes, as the codes are often being changed and updated in many communities. Before making any changes, I would suggest learning the exact facts applicable to your own situation. A licensed electrical contractor will be able to inspect your wiring and suggest what changes would be desirable or required.

I am in full agreement with Mr. Muessig's excellent suggestion that any overheated items be replaced and bad connections corrected.—K4KI.

OOPS!

Oops! I'm only fifty-six and I certainly wasn't any child wizard with electronics, but "fifty years a ham and long-time member of QCWA" is about the nicest thing anyone could say about me even if it isn't correct (see October, 1978, issue of *73*, page 6)! My letter of July 24th providing you with the original artwork had reference to Larry Harvey N6LY for whom I did the sketch—he fits that description. He's the ham responsible for producing the fine printed program of the San Diego Convention and deserves recognition for a job "well done," most especially in view of the lack of help and cooperation which he had to overcome.

Keep the League's tender spots exposed to the stove, Wayne. The pages of *73 Magazine* certainly give the amateur radio community much to think about and use in every facet of this great hobby. May your tribe increase—also your ad contracts and subscriptions!

Paul Hower WA6GDC

GOLD STAR

The good guys still outnumber the bad guys in the mail-order business. In the spring of 1978, I ordered a gear set and service manual for a Lorenz Teletype™ machine over the telephone. I paid $48.00, in advance, for the order. The person accepting the order misunderstood and sent gears for a Model 15. I was advised the manual was not available from the advertiser. Subsequently, the advertiser had a machinist cut a pinion gear and I received my three made-to-order gears. I forgot about the manual. Recently, I received an unsolicited check for $26.00 as refund on the manual not delivered. A *gold star* advertiser—Teletypewriter Communications Specialists, Berkeley Heights, New Jersey.

COMPUTER USER'S NET

There has been established a 2650 Computer User's Net every Thursday at 2330Z on a frequency of 3.993 MHz. The net is an informal net dedicated to the discussion of the 2650 in particular and personal computing in general. Most of the net participants are using the Central Data 2650 system and they are eager to talk to any and all.

The present net control station is Jerry Johnson WA3WZF, Fort Meade, Maryland, and it is hoped to expand the net to a 20 meter version also.

Sneaky Car Security System

—an alarming article

The recent visit to my van by an "uninvited guest" gave me the impetus to start construction on a radio-controlled electronic locking and alarm system which I have contemplated building for some time. Most standard automotive alarms have certain disadvantages, such as time-delay units which allow 30 or so seconds for entry. A professional thief can have the door to your car opened, radio out, and be halfway down the block before your siren goes off! Lock-actuated systems possess the negative feature of having to punch a hole in the body of your car. They are also a dead giveaway to the "pro" as to what type of protection you are using. But my particular design utilizes a small battery-powered transmitter to activate and deactivate the alarm/receiver, without any direct connection to your vehicle.

Almost all of the digital circuitry is from the CMOS family, which is a natural for automotive applications because of its wide supply voltage range, excellent thermal character-

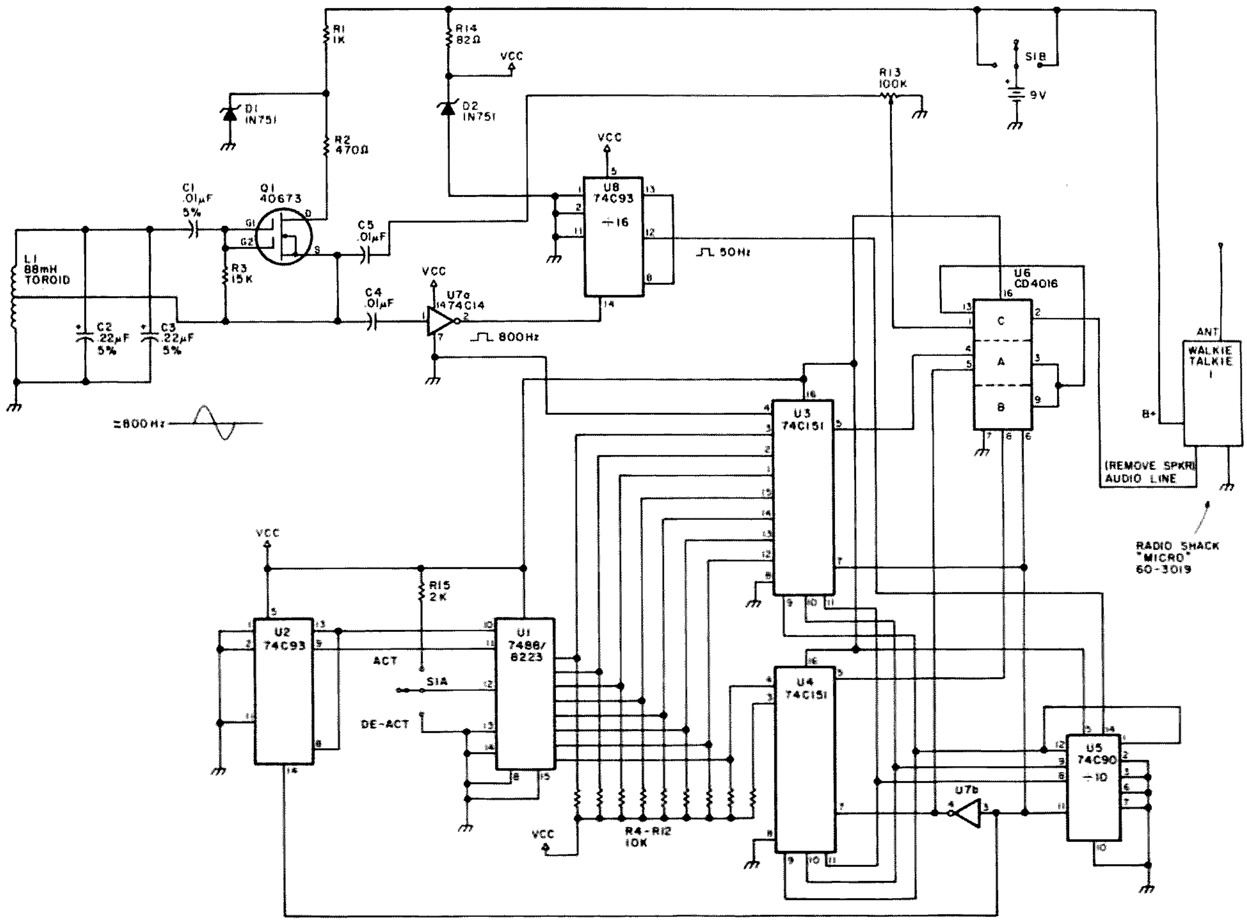

Fig. 1.

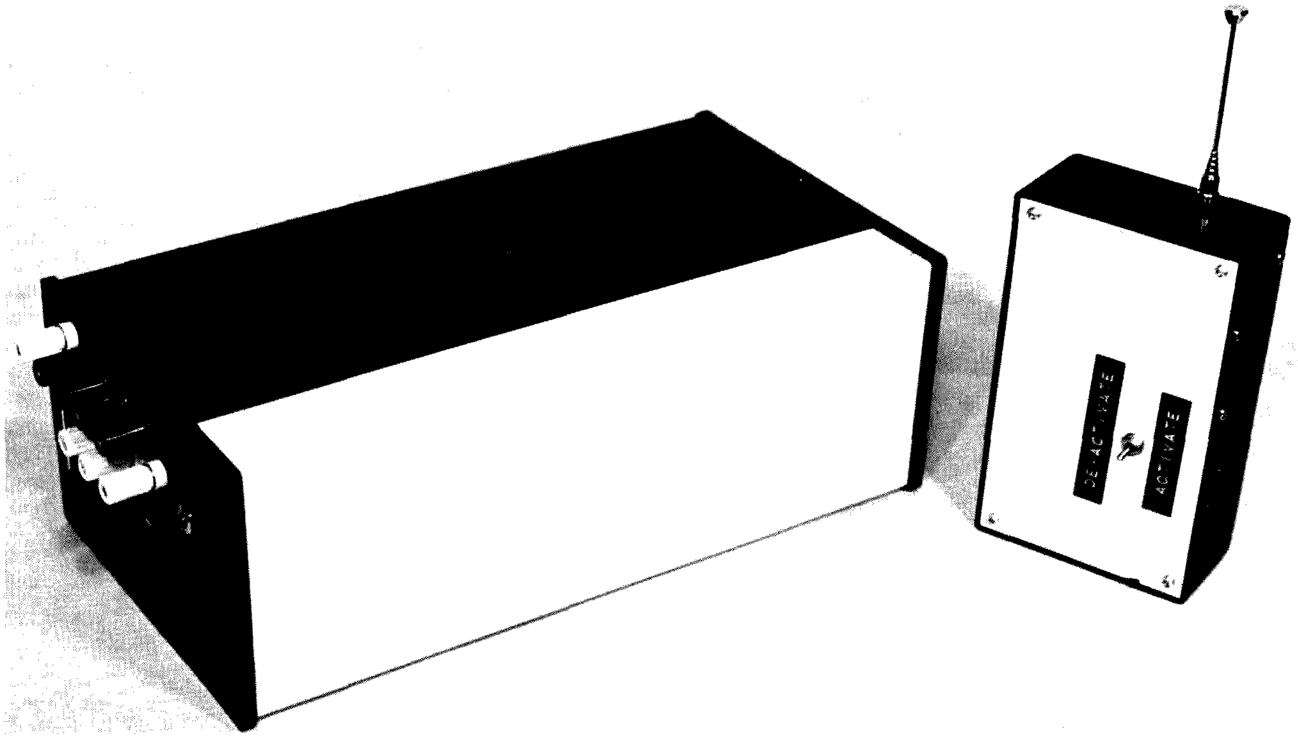

Receiver and companion transmitter.

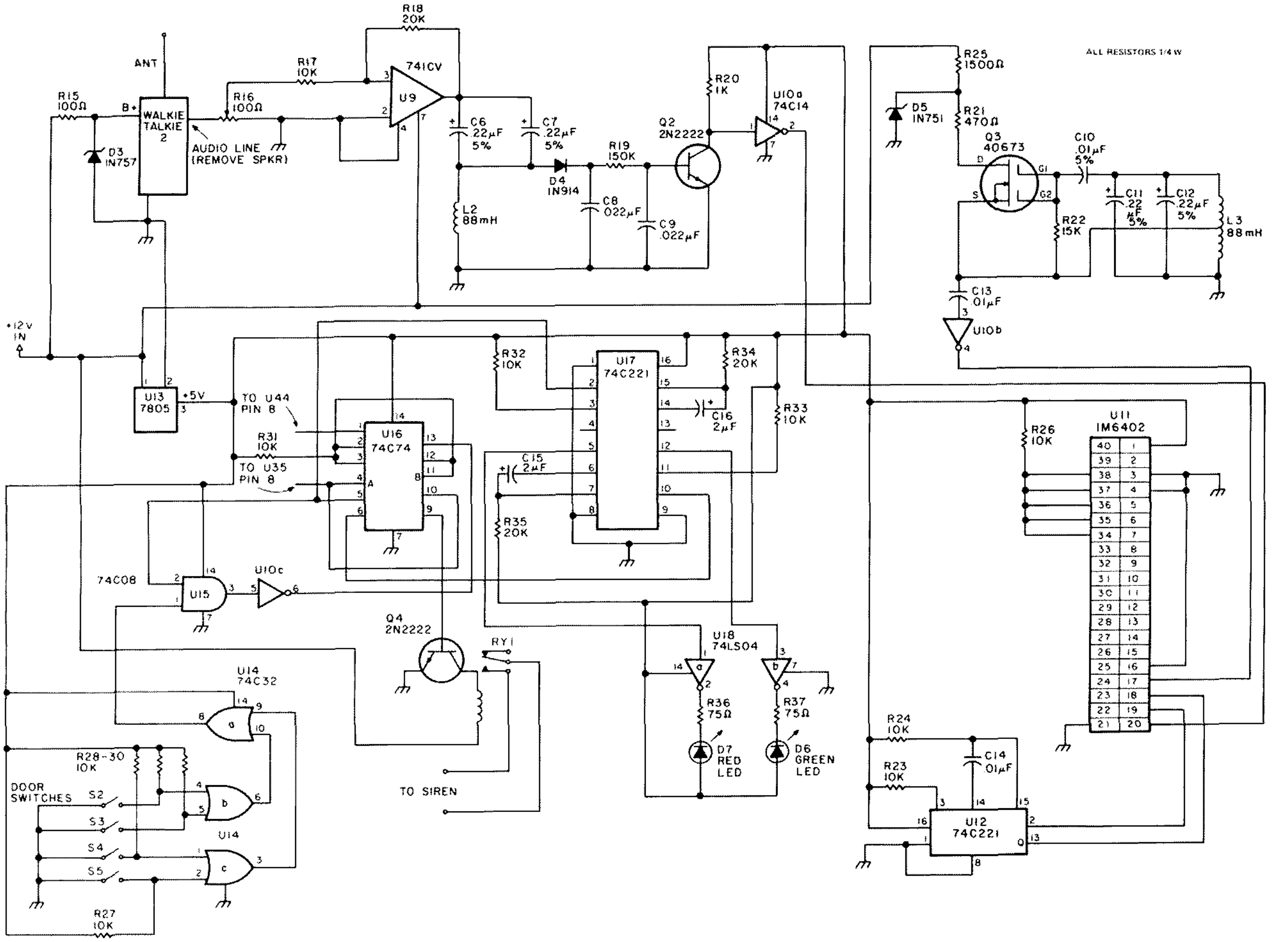

Fig. 2. Rx/logic control. All resistors are ¼ Watt.

istics, and extremely low power consumption. To keep the project as simple as possible, a set of inexpensive walkie-talkies are used as the rf link.

Transmit System Description

Refer to Fig. 1. The transmitter logic centers around U1, a 32 x 8 bit ROM of the 7488 or 8223 variety. These memory chips can be bought, preprogrammed with random bits on the output, through the surplus market for a few dollars each, or they can be purchased new and programmed by the buyer. A four-word address sequence is generated by a 74C93 binary counter, U2, and the activate/deactivate switch, S1. The two remaining address lines are hard-wired to ground. A different eight-bit parallel output is produced each time the address changes. The ROM outputs are then routed to multiplexers U3 and U4. On U3, the first bit is locked low, and, on U4, the second bit is locked high. Since the multiplexers are sequenced with a 74C90 decade counter (U5), the count on U4 will never progress past the second input. The end result is a ten-bit TTY format signal at the output of OR gate U6A/B, with the data changing 1 address each time U5 completes a count of ten. The baud rate is controlled by the MOSFET oscillator and runs at approximately 50 Hz using the components specified. The output is split off at the source of transistor Q1, with one leg passing through the 74C14 Schmitt trigger (U7) and divide-by-16 counter, U8, and drives counter U5 at 50 bits per second. The second leg of the oscillator is the audio source for the data modulator U6C. The TTY signal controls the audio tone by producing ON/OFF keying in direct proportion to the digital data. The output of the analog switch is then used to modulate the transmit walkie-talkie. The unit should be modified by removing the microphone/speaker and connecting the data modulator output directly into the walkie-talkie audio line. Audio level is controlled by potentiometer R13 and should be set for minimum distortion by monitoring it with an oscilloscope at the output of the second walkie-talkie. It is also necessary to lock the TX/RX switch in TX. This is accomplished by removing the PTT button and bending the switch arm around to the foil side of the PC board where it should be soldered in place to the ground pad.

Receive System Description

Refer to Fig. 2. The encoded signal is picked up by walkie-talkie #2 with the audio tone level controlled by R16 and boosted by op amp U9. C6, C7, and L2 comprise a frequency selective network which allows only the 800 Hz tones to pass. D4 detects the signal, and C8, C9, and R19 filter it. Q2 clamps the voltage so that it can fire Schmitt trigger U10A, whose output is the restored digital data. This data is then applied to the serial input port of U11, a 5-volt UART. Clocking to U11 is provided by a second MOSFET oscillator,

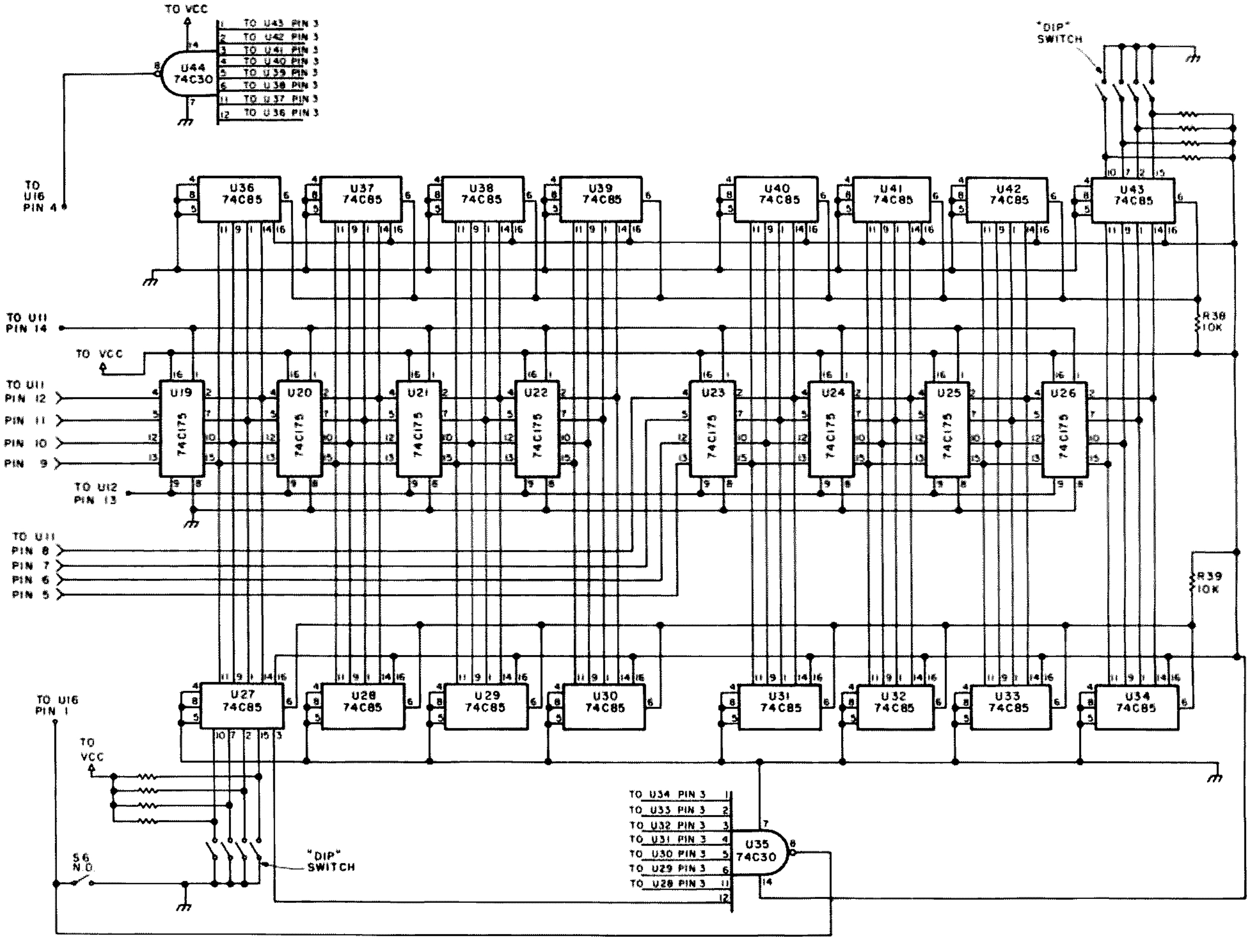

Fig. 3. 10k pull-up resistors and switches on all pins 10, 7, 2, and 15, ICs U36-U34.

 Jan 1979

which is essentially the same circuit as the transmit oscillator. The output of the UART is a succession of eight-bit parallel words which are decoded by the circuitry in Fig. 3. The decoder provides a signal when it senses an "activate" command which sets flip-flop U16A. When the Q output (pin 5) goes high, it arms AND gate U15. At this time, if any of the other switches (S2-S5) are opened, the output of U15 will change state, causing U16B to latch, which turns on Q4, trips the relay, and sounds the alarm. Once U16B latches, it is not possible to reset it by merely closing the door. The turn-off command must come from the transmitter or from a reset switch hidden inside the vehicle. To ascertain that the receiver has actually picked up the activate command, a visual indication system is provided. When U16A arms, it triggers one-shot U17, which produces a half-second-wide pulse that blinks red LED D7. When U16A disarms, D6, a green LED, will also blink, indicating that the vehicle can be entered without setting off the alarm. These two LEDs can be mounted in an inconspicuous place near a window to aid visibility.

Decoder

Refer to Fig. 3. The eight-bit codes enter the shift register chain simultaneously through U19 and U23. Here they are clocked down the line by U12, which provides a pulse each time it recognizes that a valid word has been received by U11. U12 also produces the data reset command for U11. At this time, a constant comparison is being made by ICs U36 through U43 and U27 through U34, which comprise the respective activate and deactivate command recognition circuits. Preselected values which match the activate and deactivate codes are set into the comparators by DIP switches. When the data at the shift register outputs is the same as those preselected values, the A = B outputs of the comparators will go high, and, when all eight go high concurrently, their associated NAND gates will go low, causing U16 to either set or reset. If no changes in coding are anticipated after the initial setup, it is not necessary to use the DIP switches. Instead, the codes can be hard-wired into the comparators. It's not even that difficult to change codes with this technique, especially if wire-wrap construction is used. As an added security measure, all the shift register clear lines are tied common and wired to the UART framing error flag output. In the event of noise, quite often the UART will output a random "word," but it also

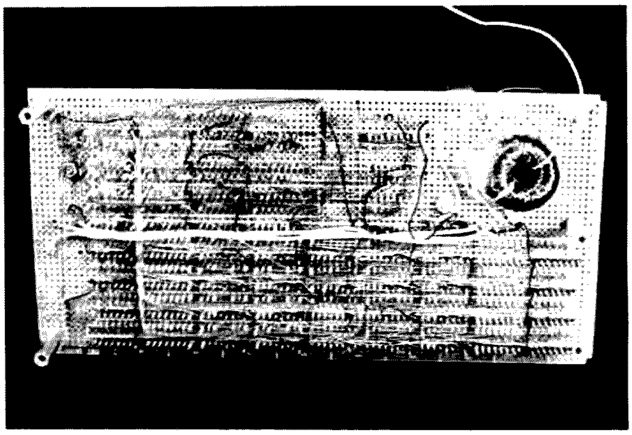
Receiver circuit board. Receive rf board is in the upper right-hand corner. To its left are the tone-to-data converter, UART, and shift register chain. The bottom half of the board contains the digital comparator and logic control circuits. I/O connectors are on the extreme left, upper and lower.



Rear view of receive board. Filter coil is in the upper left-hand corner.

recognizes that it was triggered from noise and will pulse the framing error flag high. This pulse will cause the shift registers to dump any erroneous data in them, thus decreasing the possibility of accidental activation or deactivation due to noise. Push-button switch S6 is used to manually reset the alarm by producing a negative-going pulse. The momentary short circuit across U35 will cause no harm to any circuitry.

Operation

It is only a matter of throwing the activate or deactivate switch and observing the receive indicator LEDs for proper operation. The transmitter is designed to send a continuous string of data, for the receiver only has to miss just one data bit for the commands to be ignored. It is better to send the data continuously and then turn the transmitter off after it has been verified that the command has been properly received.

Conclusions

Designed initially as an automotive protection system, the basic circuitry can be adapted to suit a host of other needs, such as home protection or as an automatic garage door opener. Power supply requirements are extremely low. In the arm mode, about only 50 mA of current at 12 V dc is all that is needed. This suggests battery power as a primary or backup source which would sustain protection to, say, a house during a blackout — or if someone cut your ac lines!

There are so many variables present that it would be extremely difficult to try to "crack" the receiver by means other than what it was designed for. Transmission and modulation frequencies, data rate, and code combinations are just a few of the parameters which can be changed. At the other extreme, this particular unit was designed as a prototype, and the coding scheme is more complex that it really has to be. Eight bits per word, multiplied by four words for each command, results in 2^{32} possible code combinations (more than 4 billion)! If this much security is not needed, remove the wire from U2, pin 9 in the transmitter and ground it. This will result in only 2^{16} code possibilities (65536). However, U21, U22, U25, U26, U29, U30, U33, U34, U38, U39, U42, and U43 can all be deleted. Other ways to decrease complexity would be to use only a four-bit data word.■

Design-a-Notcher

—automated filter values

Personal computers have been around for several years now and it appears that many of them spend most of their time playing games. I think we should start making them do some honest work for us. The following program will compute the variables used in a notch filter. The variables are the R or C terms. The program was written for an SWTP system using 8K Basic.

A notch filter, as its name implies, is used to notch out a certain frequency. The desired frequency will be notched out and certain side frequencies will be attenuated. The number of side frequencies attenuated will depend on the depth of the notch and the sharpness of the notch itself. The notch depth is determined by how well the components are matched. Theoretically, infinite attenuation is possible, but the mismatch of components limits the total attenuation to less than the theoretical limit.

The frequency where the notch occurs is dependent on the values of the RC components in the following equation:

$$F_n = 1/2\pi RC$$

where F_n is the notch frequency.

To use the program, one must know the resistance of the source feeding the filter and the resistance of the load being fed by the filter. The filter works best when working into an open load, which is not practical, but it still does quite well with a load across the output if the load resis-

Program listing.

tance is high compared to the source resistance and the resistance in the notch circuit. For best results, the following ratio should be adhered to: RS < R < RL.

Notch filters are popular, but their use is limited to frequencies below approximately 400 kHz, and they tend to have high attenuation and low selectivity. But, because of their simplicity, low cost, and ease of design, they are widely used.

The sample run of the program uses RS equal to 600 Ohms, RL equal to 10k Ohms, and a desired notch of 1 kHz.

Fig. 2 shows the circuit that the program developed. Note that it does not notch out at exactly 1 kHz. The reason for this is that with the values of .1 uF for C vice 1.0615 · · ·, the value of R should be 1592 Ohms and R/2 should be 796 Ohms. I am reasonably sure that the notch would have been nearer 1 kHz if more exact values of R were used.

If you have need for a notch filter and use a computer that speaks BASIC, this program will allow you to play with different values and see how they affect the depth and sides of the notch.■

The Cosmac Connection: Part 1

—computerized CW

With a few ICs and this program, your Cosmac microcomputer can imitate the best automatic keyers available.

A simple 90-byte program can turn your Cosmac microcomputer into an excellent automatic keyer for sending Morse code. It features automatic dash and dot completion, dash and dot memories, adjustable dash:dot ratio, automatic letter spacing, iambic or squeeze keying, and adjustable speed from 5 wpm to 80 wpm.

Equipment Required

You will need the Cosmac microcomputer fashioned around the CDP1802CD CPU by RCA. The program requires 90 bytes of memory. My computer was constructed according to the article which appeared in *Popular Electronics*, September, 1976. In addition, you will need some ICs and perhaps a transistor or relay in order to interface the computer with your transmitter. The program was written for a clock frequency of 1 MHz, but it can be modified for other clock frequencies quite easily.

How the Program Works

After setting subroutine counters and memory pointers, the first thing the program does is convert the code speed entered via the keyboard into hexadecimal form. The program assumes the code speed will be less than 100 wpm. An example will illustrate the method best. Suppose you enter 35 as your desired speed. The program converts this to base 16 by repeatedly subtracting 10_{16} from it until the remainder is less than 10_{16}. In this case,

$35_{16} - 10_{16} = 25_{16}$
$25_{16} - 10_{16} = 15_{16}$
$15_{16} - 10_{16} = 05_{16}$

Each time a subtraction is performed, OA is added to R1, and, finally, the remainder is added to R1. In this case R1 = 0A + 0A + 0A + 05 = 23_{16}. This completes the conversion, 35 wpm = 23_{16}.

Next, I derive a number which is proportional to the length of one dot. Since the length of a dot is inversely proportional to the code speed, I calculate 00F7/code speed in hex form and store the quotient in M(000A). This number sets the length of a timing loop in making a dot. Two times this number is used for letter spacing, and three times this number is used for the dash length. Actually, during execution of the program, a dot or dash is automatically followed by a space of one dot, and, if a letter space of two dots is added to this, you get effectively a letter space equal to the length of three dots.

Spaces were left at M(0048) and M(0049) to enable you to increase the length of the dashes. By inserting the instruction F4 at M(0048), the dashes will be 4 times the dot length. If you also put F4 at M(0049), the dashes will be 5 times the dot length. This will change the speed of the code, of course.

The dash length is stored in M(000C), and, since it cannot exceed FF, this restricts the maximum dot length at M(000A) to 1/5 of FF if you use a 1:5 dot-to-dash ratio. This, in turn, places a maximum value on the numerator of the formula quoted earlier, 00F7/code speed in hex form. So, summing up, the number 00F7 was chosen to allow code speeds as low as 5 wpm without exceeding a dash time of FF at M(000C). At M(0036), provision is made for changing this numerator to 01F7 or 02F7, if desired. This is useful when operation will consistently be at high code speeds and when finer resolution is required in the code speed. For example, with the program as

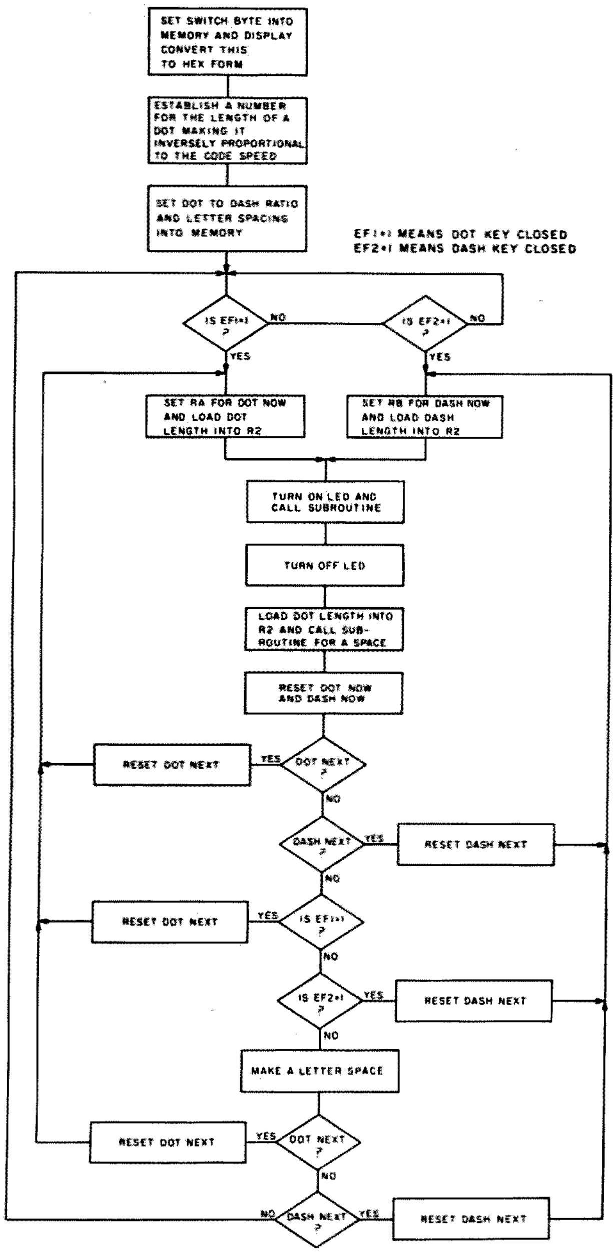

Fig. 1. Flowchart for automatic keyer.

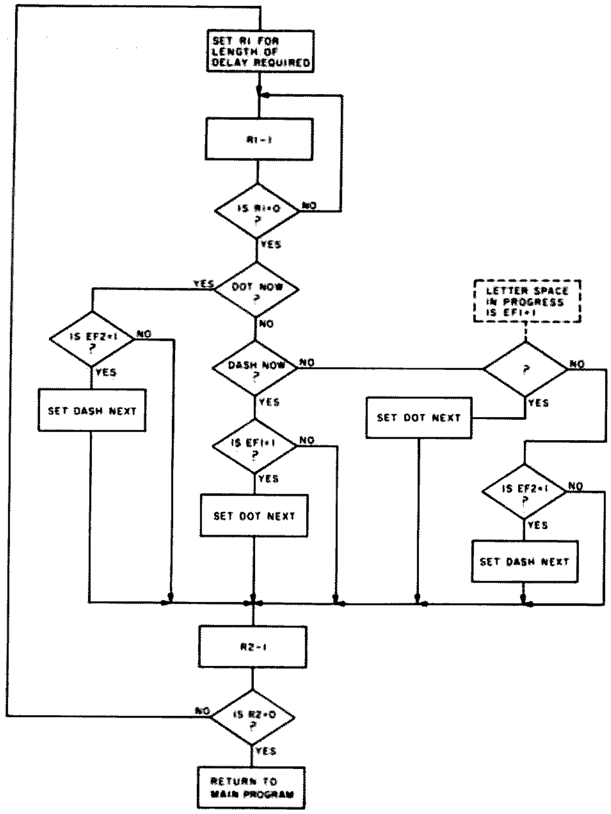

Fig. 2. Timed subroutine flowchart.

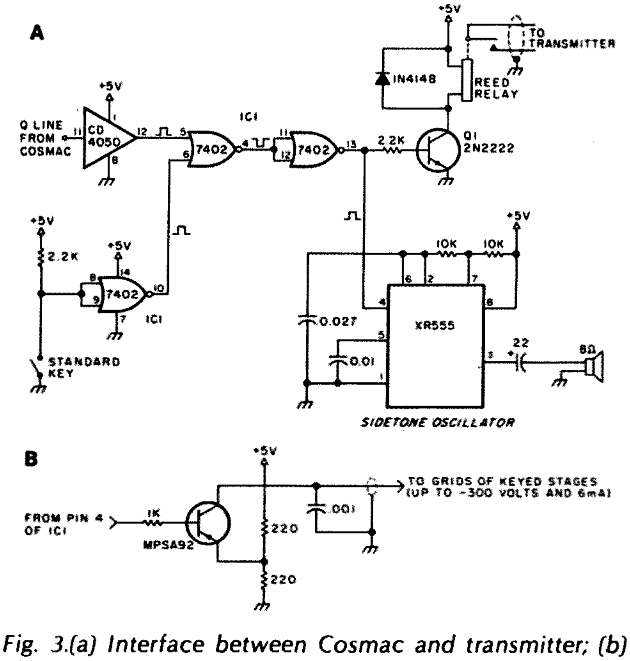

Fig. 3.(a) Interface between Cosmac and transmitter; (b) alternate circuit for rigs with grid-blocked keying eliminates relay and Q1.

is, you get the same speed of code whether you enter 25, 26, or 27 wpm. The speed changes at 28 wpm, but remains at this new speed whether you enter 28, 29, or 30. The problem is accentuated at very high speeds. For example, you get the same speed of code for all entries between 62 and 81 wpm.

The rest of the program is straightforward and is understood best by looking at the flowchart. The key is connected to $\overline{EF1}$ and $\overline{EF2}$. Closing the dot side makes EF1 = 1. Closing the dash side makes EF2 = 1. The program periodically checks the status of these inputs, and the dots and dashes come out on the Q-line, which is interfaced with the transmitter as described later.

The subroutine in the program is simply a timed loop using registers R1 and R2. The initial value of R2 is set before entering the subroutine according to the length of delay required, whether a dot, dash, or letter space is being generated. At a code speed of 24 wpm, you should get 10 dots per second. For a 1:3 dot:dash ratio, the length of a dot at 24 wpm should be 50 ms. Accordingly, the values of R1.1 and R1.0 were set at M(009C) and M(009F) so that the dots are the cor-

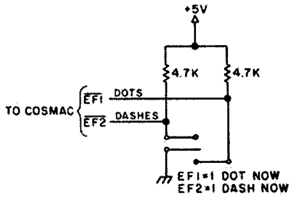

Fig. 4. Key connections.

rect length at this speed. They will automatically be the correct length at other speeds because the number in R2 is proportional to the code speed. The values chosen for R1.0 and R1.1 assumed a clock frequency of 1 MHz. It should be a simple matter to adjust these figures for different clock frequencies, although I have not tried anything but a 1 MHz clock.

Interface Circuitry

The connection of the computer to the transmitter is shown in Fig. 3. It includes a sidetone oscillator for monitoring your code and also an input for a hand key which I like to use when tuning up the transmitter or when the computer is programmed

Table 1. Register assignments.

as an automatic message generator instead of an automatic keyer. Fig. 4 shows the method used to connect the key to the computer.

If your transmitter is running more than a few Watts, you must be careful that your wiring does not pick up rf in the shack. If it does, it may upset the logic gates, and you'll find that, once the first dot or dash is sent, the transmitter might not shut off. This rules out any long dangling wires running across your desk in front of your transmitter! For best results, use a shielded enclosure and bypass the leads to the transmitter and key with 0.001 uF ceramic capacitors.

Using the Keyer

Enter the program shown and, before setting the computer to "run," enter the desired code speed from the front panel. Set the computer to "run," and your speed will be displayed on the hex display. To change the speed, just set the switches on the front panel to the new speed and flick the run switch off and then on. Some people find the automatic letter space a bit awkward at first, probably because their fist, like mine, has become a little sloppy over the years. To eliminate automatic letter spacing, enter the instruction C4 at M(007F). C4 means no operation, and the subroutine normally called at that location does not get called.

So, for your next QSO, try out this nifty keyer and tell the operator at the other end that he's talking to a computer! He'll have no excuse for not being able to read your fist. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

were running thousands of Watts in order to win the Sweepstakes contest and then taking the 100-Watt multiplier.

The saying that an antenna is not big enough unless the winter brings it down came from Sam. His Medfield home was surrounded by enormous towers with beams for all bands. Sam was one of the first to consistently get his signals back from the moon on 144 MHz. This activity progressed to a couple of big dishes, and eventually were his ticket to working as an engineer at the world's largest dish at Arecibo, Puerto Rico.

Sam would never actually admit it, but I think my own activities in New Hampshire helped drive him out of the country. I mentioned his deep need to have the loudest signal on a band. Was it a coincidence that shortly after I put up 336 elements on 2m on a mountain not far from *73* HQ that Sam moved to Arecibo?

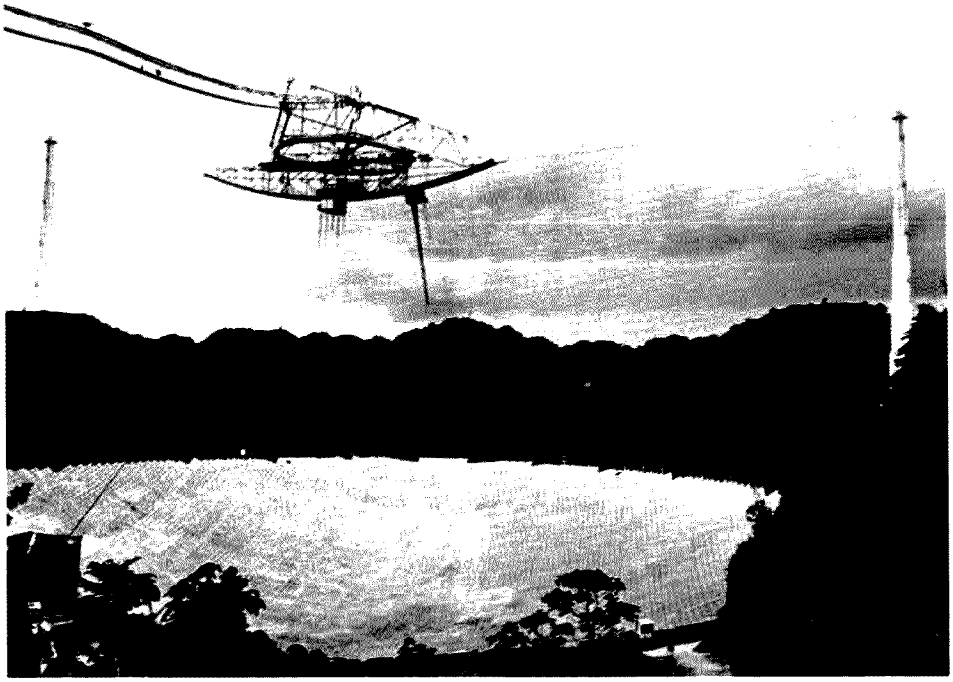
At the time, Sam had been working for Microwave Associates, helping them sell his parametric amplifiers. Sam called me one day to say that he had been fooling with a very high gain amplifier on six meters and had gotten it working. Before this there had been some articles predicting that something like that might work but no one had ever built one. It not only worked, but it was so powerful that they were soon being added to virtually every US radar installation in the world.

Sam wrote an article for me on it, and it happened to be published in an April issue of the magazine. Many readers thought the concept so outrageous that the article must be an April Fool.

After Sam moved to Arecibo, he got the laboratory there interested in amateur radio moonbounce. I made a trip down to participate in the 1296 MHz moonbounce experiments. The dish had so much gain that the band sounded like 20 meters during a contest. That was an experience which will never be forgotten.

Getting time allocated on the big dish was so difficult that Sam started building his own fixed dish with a movable antenna pointing into it, a small replica of the big one. After he got this dish working well, he was loaded with so many laboratory uses for it that he seldom had time to get set up for ham moonbounce work.

We have so few pioneers such as Sam that we can ill afford to lose them. I would be hard put to name one other amateur who has done as much for amateur radio as Sam.



W1FZJ's dish at Arecibo.

SEPTEMBER WINNER

Our readers religiously voted for Thomas R. Sundstrom W2XQ's article, "The SWL Bible," as the most popular in our September issue, so he will be receiving *73*'s $100 bonus check for that month. Don't forget to use *your* Reader Service card ballot!

WRIST RADIOS

For those of you who have not been reading the more obscure technical journals, be advised that there is a strong move afoot to augment the present telephone system with a wrist radio which would work on about 5 GHz. This would run about 25 mW and would work through a series of satellites.

The radio would have an LED which would tell you when you were within working range of the satellite. This would be accomplished by the reception of

Noise Bridge BASICs

—computer-optimized radiation

This program makes sense out of those funny readings on your noise bridge.

Terry A. Conboy N6RY
1231 Crestview Drive
San Carlos CA 94070

One of the most useful tools that the antenna experimenter can have is an antenna noise impedance bridge. This handy device allows you to find not only the resonant frequency and swr of an antenna, but it also lets you find the actual impedance at the antenna, which is decidedly handy when adjusting matching networks. It is portable and does not require you to operate your transmitter to make measurements, which helps to reduce the already ridiculous QRM levels on the bands.

The only thing that is particularly inconvenient about a noise bridge is making use of the indications that it gives. Unless you use a feedline which is a multiple of a half wavelength, the reading on the bridge is not the impedance at the antenna. It isn't very convenient to find the swr, either. The Smith chart is a very usable graphical tool which will allow you to find both the impedance at the antenna and the swr. There is a learning period on the Smith chart, and, even after you understand its use, it is still easy to make silly errors and get the wrong answer. And, since it is a graphical method, there are small errors due to "eyeballing" the lines and circles. This isn't a serious problem, however, considering the accuracy of the bridges available to most amateurs.

The BASIC program given here does all of the dirty work for you. It will accept readings from any of three different types of antenna noise bridges and output the antenna impedance in series form (R + jX). It also gives the swr on the feedline. The only

A	Angle of complex antenna impedance in radians
B*	Z tan (P) + W
C	Reactance or capacitance dial reading

Fig. 1. Program listing.

assumption is that the feedline is lossless, which works out well in practice. Most feedlines used in the frequency range where the bridges are most useful do not have significant loss.

Of the three types of bridge which may be used with this program, the simplest is the resistance-only bridge, such as an Omega-t unit. These are very popular, but they will only give a deep null when the unknown impedance has a nearly zero reactive component. Often you can find only one or two nulls in a band. More nulls may be obtained if you add another chunk of feedline to the normal feeder. The nulls will then move to different frequencies. Be sure that you have a good null, or the output from the program will be in error.

Another popular commercial bridge is the one sold by Palomar Engineers. This bridge has a "reactance" dial in addition to the resistance dial. This dial varies a small series capacitance in the bridge circuit. (In fact, the dial is really calibrated in picofarads, even though it is labeled "XC" and "XL".) Use of this dial should let you find a null for almost any impedance at any frequency. This wide range is a liability at times, though. A small error in reading the dial can give a fair amount of error, especially at lower frequencies. Notice that the program considers "XL" readings to be positive and "XC" readings negative.

The third type of bridge we'll call the W6BXI—W6NKU bridge, after the two hams who brought this circuit to a state of perfection.[1] It, too, has a variable capacitance, but the capacitor is connected in parallel in the bridge. The dial is calibrated in positive and negative picofarads. (A negative picofarad is what resonates the inductive reactance at the measuring port of the bridge.) These parallel-type bridges have a somewhat restricted range of reactances for which they will provide a null, particularly at lower frequencies. To extend the measurement range, a coaxially-mounted resistor is placed in series with the feedline connection at the bridge. This improves the ratio of resistance to reactance and often permits nulling the bridge. The value of this range extension resistor must be input to the computer (zero Ohms if not used).

The program is broken up into nine sections. The "100" section lets you specify the type of bridge you are using. In the "200" part, you input the parameter of the feedline. Velocity factors greater than 1 are not allowed. (If you find a feedline with this characteristic, sell me part of it!) In section "300", the measurement frequency and resistance dial reading are input. If you input a zero frequency, it terminates the program run. If the resistance dial reading is zero (doubtful), the program substitutes 10 milliohms to avoid division by zero later.

Section "400" calls the subroutines needed for the type of bridge that you have specified. These three subroutines input any other readings needed, make allowances for out-of-range values, and convert the readings to the series-equivalent impedance seen at the bridge end of the feedline. If a negative resistive component is present, the program bails out to prevent meaningless results.

In sections "500" and "600", the equivalent length of the feedline in radians is found and is used to transform the impedance at the bridge to the impedance at the antenna. This impedance is then printed. The last section of the main program, "700", computes the magnitude of the reflection coefficient and uses that to calculate the swr.

Table 1 lists the variables used and indicates what they represent. This may help you adapt to other languages or make modifications. If you are only interested in one of the three types of noise bridges, you can de-

lete the branches to the subroutines for the undesired types of bridges to shorten the program.

The only thing that might be a bit different about the Quodata BASIC compiler used on the PDP-8/e is that it doesn't allow for prompts as part of an "INPUT" statement. This was circumvented by using a "PRINT" statement followed by a semicolon to suppress the line feed.

To check for proper operation of the program, Table 2 shows three different sets of input data which will give nice round answers for most of the outputs. The inputs simulate feedline lengths at multiples of one-eighth wavelength. The six-digit input values should give outputs within one-tenth of an Ohm. Obviously you can't measure your antenna this accurately, but at least you'll know the program won't interfere with your answers.

In actual use, don't be surprised if the swr that your noise bridge indicates is somewhat higher than your trusty old swr meter. The normal reflectometer-type swr meter usually reads optimistically, especially when it is not driven with a great deal of power. This is probably due to detector diode nonlinearity at low power levels.

With this program you can speedily optimize your radiating system. Take care that the switching noise from your CPU doesn't interfere with the noise nulls, or you might have to go back to the Smith chart! ■

a guide signal from the satellite. In order to get the antenna gain needed to pick up these low-powered radios, the satellites would use 68 dB gain antennas, with about 7000 of them covering the country.

A study of the project has been made by NASA and their estimates of the cost for the use of the system run to about one cent per minute, about one-tenth that of Ma Bell's costs. The watches are estimated to cost about $10. It is hoped that the system will be operational in about ten years.

YOUR HAM DEALER

If you don't see *HR* and *HRH* magazines at your local dealer in the future, chalk it up to a stupid blunder. Dealers are really upset over this and are not only canceling their monthly copies of the magazines, but also are canceling advertising and even leaning on manufacturers to stop them from advertising.

How come all the uproar? It stemmed from an article which was full of bad advice for ham newcomers on buying rigs. One of the parts that really got to the dealers was the claim that dealers don't service new equipment, they just send it to the factory, so who needs a dealer to back up a new equipment purchase?

It was bad enough that someone wrote this baloney, but for a magazine to publish such rot seems inexcusable. The fact is that any reputable dealer has an enormous investment in test equipment so he can service ham gear and perform warranty service. Most test benches these days run from a minimum of $35,000—and many double that. It takes two or three technicians to keep up with the service situation for most stores. The dealer knows that he *has* to provide this service if he is going to stay in business and keep his customers coming back.

What about factory service? Ask *me* about that, if you want your ears pinned back. I get most of my ham gear directly from the manufacturers or the importers since it is sent to me for evaluation. Obviously, they send me equipment which has been checked out and should be in pretty good shape. Despite this, at least one third of the equipment I get craps out within a few days and has to go back for service. It is a sorry fact of life that few manufacturers of ham gear put their equipment through the burn-in tests which most commercial equipment suffers. This means that early part failure happens *after* you get the rig instead of before.

This is by no means an indictment of the manufacturers. They are forced to cut corners on design, construction, and testing in order to be competitive in the ham market. If you look at almost identical commercial equipment made by the same firms, you'll find that it costs half again as much in most cases. This is not because the manufacturers are making a bigger profit—it's because they are putting out a much better product, one which the customers are willing to pay for.

Few hams are equipped to deal with the aches and pains of modern high-density synthesized equipment . . . and even if we are game to spend a few days chasing some glitch, we feel that, dammit, the rig is under warranty, so why should *we* go through all that trouble.

Now, if you've bought the rig from a reputable dealer, all you have to do is get it back to him. In some cases, if the rig is still brand new and he has another, he may well give you another rig in its place. But at least he has the repair equipment and technicians to tackle the problem, plus the service data from the factory to help him quickly isolate the difficulty.

My own experiences with getting equipment repaired by the factories have occasionally been so bad that it is unbelievable. And if *I* can't get service from a manufacturer, how can *you*? I've had rigs come back to me two and three times either in worse shape than they went out or with no improvement whatsoever. I've had rigs take months to get fixed. There's one piece of equipment which is at the factory right now . . . and has been in and out of there for almost two years, with not one day working right in between. When I call to find out what is happening, I'm sure they put the rig to the back of the line again.

Sure, there are some factory service departments that are wonderful. But, on the other hand, there are some importers who do no service at all. If you can't get your rig fixed by your dealer, it will have to be sent to

The Morse Master

—convert your computer friends to hamdom

A novel use of the MID$ function is only one feature of this relentless program.

William A. Thornburg WB9TNW
RR 2
Thompsonville IL 62890

There have been a few articles lately in the microcomputer literature concerning the creation of a radio network for the interchange of information. It has been mentioned that the amateur radio service would provide a natural environment in which to implement such a network.

For several years, amateurs all over the globe have been exchanging "files" in the form of slow scan television. These "files" are of a special nature, but they are still streams of data in the long view.

The ability to use radio for information exchange should be easy for the average computerist to develop. However, there are three major hurdles to overcome.

The FCC must approve the use of ASCII in the amateur radio service. This, I hope, is a formality whose time will come. Secondly, there must be a set of hardware/software protocols developed, so we can dance to the same tune when using the system. There are some bright people working on this, and we will surely hear more about this in the future.

Last, but not least, one needs a license to operate a transmitter in the amateur radio service. A ham license is the key that unlocks the door to an entire world of adventure in amateur radio. To get a license, you must pass a written test and a code test. The international Morse code must be mastered at various levels of difficulty, corresponding to the different licenses.

Stop a minute and consider this combination. I am sure serious computerists would be welcomed to the ranks of amateur operators and would find a niche in the amateur structure to enjoy this unique blend of electronic wizardry. I am also sure computerists would enjoy the unique experiences that only amateur radio has to offer. The potential for increased enjoyment is tremendous. Can you imagine discussing and swapping algorithms with a fellow ham computerist in Australia via the 20 meter ham band? How about accessing your computer by using your two meter hand-held radio and touchtone™ pad while cruising down the highway or fishing on some remote river? And, some of the brightest inhabitants of the Silicon Valley can be heard on the ham bands discussing the latest in hardware, software, and techniques. (I hear a lot of computer discussion in the advanced portion of the 20 meter band.) The list of possibilities is endless when you combine these two activities.

I repeat: To be a ham you must get a license; to get a license one must learn the code. The code is not the awesome obstacle that some make it out to be. It can even be a lot of fun. To further learn about the amateur licensing structure, I suggest the *73 Novice Study Guide* and the ham magazines. These can most often be found in the local radio store.

Now that your motivational fires are stirred up, let's look at the program about which this article was written.

This program is a drill which will help you to learn the Morse code. It spits out groups of 5 randomly-selected characters by sounding the proper Morse dit/dah patterns, and it can also print the letters on the video terminal.

My system is all Heathkit. I have the H-8 with 16K

of memory, the H-9 video terminal, the cassette tape recorder and I/O board, and Extended Benton Harbor BASIC.

In the Heath H-8 mainframe, there is a speaker. An audio tone is counted down from one phase of the system clock and applied to the speaker using appropriate control logic which provides a means to turn the "horn" on and off. The H-8 monitor normally uses this feature to provide audio feedback and signaling in conjunction with the front panel.

Placing the number 112_{10} in location 8201_{10} turns on the tone, and a 240_{10} in location 8201_{10} turns it off. This can be accomplished by using the "POKE" command, e.g., "POKE 8201,112" turns it on, and "POKE 8201,240" turns it off. By selectively turning the tone on and off and providing the proper timing and spacing, the Morse code patterns can be formed.

The flowchart in Fig. 1 illustrates the main features of the program logic. Two nested FOR/NEXT loops control the timing between characters and between groups of 5 characters. Statements 131, 132, and 140 do the actual work of tone generation via subroutines. The inner loop and delay return a group of five characters. The outer loop provides a delay between groups of five characters.

A delay is created by a FOR/NEXT loop of the form "FOR I = I TO X: NEXT X". The timing parameter "X" is user-defined and is in arbitrary units of time.

Line 131 generates a pseudorandom number between 650 and 900, which is stored in P3. Please note that P3/10, a number between 65 and 90, corresponds to the ASCII code for the letters of the alphabet. Therefore, the command "PRINT CHR$ (P3/10)" prints the actual letter (line 145).

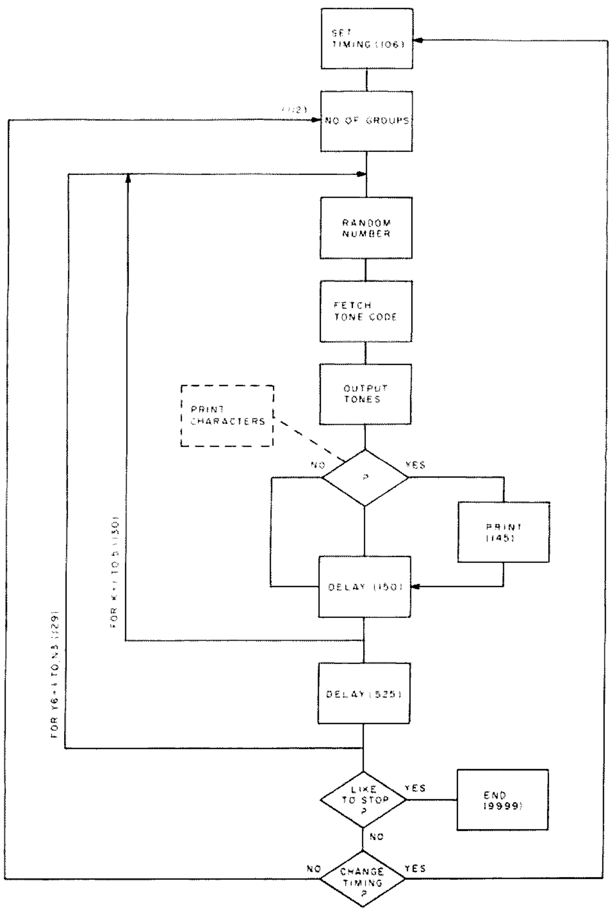

Fig. 1. Flowchart. Statement numbers are in parentheses.

Lines 650 to 900 constitute a conversion table and control is directed here as a function of the variable P3 and statement 132. A string code is placed in the string variable A$. In Morse code, there are two sounds: the short sound "dit" and the long sound "dah". A dit is encoded by a "1" in the string. A dah is encoded by a "3". For example, if P3 comes up "650", A$ is set as "13"; the ASCII code for an "A" is 65, and the Morse code is "dit dah". The letter "C" in Morse is "dah dit dah dit", and a 670 from the random number generator would cause the string "3131" to be placed in the variable A$.

With A$ charged with the proper string code, the subroutine at line 1000 produces the actual sounds. This subroutine examines each element in the string A$ proceeding from left to right. If a "1" is encountered, a sound will be emitted whose duration is governed by the timing parameter "X". If a "3" is encountered, the sound emitted will be of length "T". There is also a delay after each sound governed by "X".

Stepwise examination of the string expression A$ is accomplished by the MID$ function. This is a very handy function, and its power in string or text processing is often needed. Consider the following: R$=MID$(A$, I, J), where A$="HI THERE". If we set I=4 and J=2, then R$ becomes "TH". The string which is placed in R$ starts with the Ith character and continues until there are J characters moved (in a left to right fashion). If we use the construction: "FOR I=1 TO LEN(A$): R$=MID$(A$, I, 1):::NEXT I", then the individual elements of A$ are placed one at a time in R$, allowing action to be taken as a function of the instantaneous value of R$.

Keep in mind that the timing parameters are in arbitrary units, and what is really important is the ratio. Normally, amateurs suggest a dit/dah ratio of 1/3. I have found that a dit length of 10 and a dah length of 35 sounds good to me. As this drill is intended for the beginner, this setup should remain constant. The time between characters should be fairly long at first, say around 300 to 400.

There is another delay provided between groups of five. This is to allow the user to look up at the video terminal and check to see if he has copied the last group correctly. Therefore, if the user has optioned to view the characters, a time longer than 500 should be used. When the user no longer needs this visual feedback, he can set this timing parameter equal to that for the intercharacter delay.

As was noted, this tone is actually a square wave of around 1 kHz that is fed to a tiny little speaker inside the H-8 cabinet. You shouldn't expect it to sound like a clean sine wave coming out of your stereo. The upper limit of speed is naturally set by the operating environment of the equipment and the software.

If you terminate program execution during tone output by the "Control C" command, it is possible that the system "horn" will be left on. To shut it off, issue the command "POKE 8201,240" in "command mode." Or, you could just start the program again.

Program listing.

As a person passes through the beginner stage, it is best to practice your code copy in a more realistic manner. The method that I found best was a combination of *73's* code practice cassette tapes and listening to the ARRL ham station's (W1AW) code practice sessions.

This article started out focused mainly on the microcomputer software. As I got further into the project, it dawned on me that computer enthusiasts would be very valuable additions to the ham ranks. And, when these two activities are combined, the whole will be greater than the sum of its parts. ■

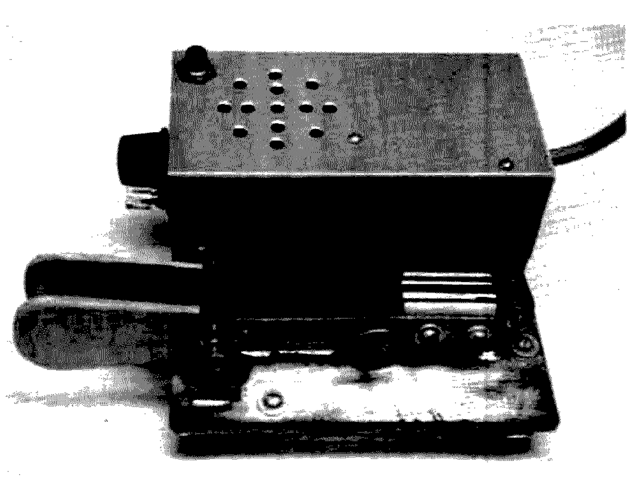
The MINI-MOUSE Key

—perfect companion to the MINI-MOS keyer

WA6EGY reveals the secret ingredients of his funny-looking key.

When my article on the MINI-MOS keyer appeared in the August, 1976, issue of *73*, many readers were puzzled by the funny-looking dual-paddle key that was shown in the photos together with the keyer. Several wrote me and inquired about the key which they thought was "built up from scraps of PC board." So, forthwith, I will reveal the secret ingredients of this mystery key, which, because of its mouse-grey, ear-shaped plastic paddles, may be referred to as the MINI-MOUSE key.

A straight key is actually nothing more than a contact that makes and breaks a keying circuit. If need arises, any contact can be pressed into service for this purpose. Some readers might remember that dramatic scene in the movie classic "Union Pacific" where the hero (was it John Wayne?) taps out the lifesaving code message by hitting his gun barrel against the downed telegraph wire. To build a reliable, easy-to-use dual-paddle key, however, is another story. The necessary low-friction bearings, lockable stops, and tension springs normally make the construction of such a key a project beyond the capabilities of the average ham. While several good dual-paddle keys are available from manufacturers advertising in *73*, none were small enough to be used with the MINI-MOS keyer. For this reason, a matching key was designed. In the design, great care was exercised to use only materials and tools that are readily available to the average ham. A close-up of the key is shown in the photo.



Close-up view of the MINI-MOUSE key mounted with the MINI-MOS keyer on a common base plate.

The material used for the construction of the key was G-10 (fiberglass epoxy) circuit board, single-sided, with a measured thickness of .046 inches. This board, which was surplus material, is somewhat thinner and more flexible than the more common 1/16 inch PC board. One starts by cutting parts 1, 8, 6a, 6b, 4a (twice), and 4b (twice) from the board according to the dimensions shown in Fig. 1. By drilling and filing, or with a fine jigsaw, one then cuts the slot in parts 4a, leaving only about 1/16 of an inch of material at the edge. These sections will later act as a flexible "hinge" around which the paddles pivot and, thus, solve the problem of the bearings. Next, parts 4a-4b and 6a-6b are laminated

together (foil sides out) as indicated by the dotted lines in Fig. 2, using contact cement. As indicated in Figs. 1 and 2, the foil on both sides of part 6 is cut 1/4 of an inch from the edge by removing a narrow strip. This can be done with a router, cross-feed table on a drill press, bit of a high-speed hand tool, or even with the blade of a hacksaw. Then one corner of the part is notched according to the dimensions shown in Fig. 1.

Next, the position for hole "Y" on part 4b and holes "U", "V", and "X" on parts 4b and 8 are marked according to the dimensions shown in Fig. 1. Parts 2 (four each) and 3 (two each) are cut from any kind of suitable plastic of the correct thickness. Next, all parts (with the exception of parts 3) are stacked together in the sequence shown in the "explosion" drawing, Fig. 2. Parts 4 and 6 should line up at the front edge, with all other parts lining up with parts 4 at the rear with part 6 protruding by about 1/4 of an inch. The whole stack is tightly clamped together or, if no suitable clamps are available, it is wrapped tightly with wire or clear plastic adhesive tape. While making sure that the corners of the stack remain lined up, holes "U" and "V" are drilled using a No. 33 drill. After the first hole has been drilled, a 4-40 screw is inserted through the hole, which helps keep the stack from moving while the second hole is drilled. Then hole "Y" is drilled, which serves the purpose of lining up the contact rivets when they are soldered in place. The diameter of hole "Y" should be chosen to center the part of the contacts protruding on the side of the spring opposite the contact surface. Next, part 1 is removed from the stack of parts and, using the screws in holes "U" and "V" to keep everything lined up, hole "X" is drilled using a No. 42 drill. Then the stack is separated and hole "X" enlarged to a diameter of about 1/4 of an inch in parts 4 and 6; but not in part 8. The contacts, part 5, are soldered in place on parts 4 and 6, using the holes to line them up, and the same is done with nut 15 on part 8. Parts 3 are cemented to part 4, as shown in Fig. 2, again using contact cement. Make sure part 3 does not cover part 4 by more than 3/4 of an inch. Parts 4 will later be pulled out by "springs" 1 and 8 respectively, with the help of linkage 10. This linkage, a short piece of flexible stranded wire or copper braid, is soldered to part 4 in the appropriate location; the other end will be connected later. Then part 6 is soldered to the ground plate along its center line, making sure the two parts are positioned perpendicular to each other, with the notch of part 6 lined up with the

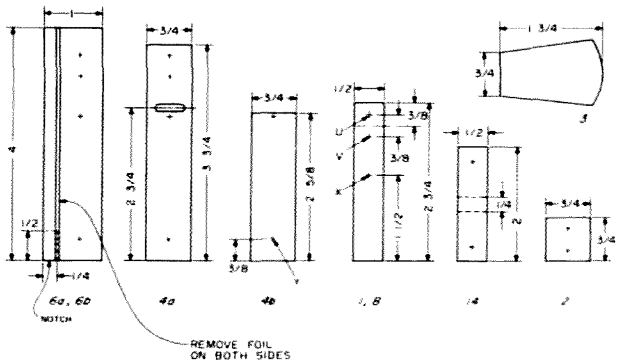


Fig. 1. Dimensions for most parts. For details of the materials to be used, see parts list.

edge of part 4.

Now, everything is ready for the final assembly. If one wants to protect the beauty of the MINI-MOUSE key permanently, however, one has to keep the copper foil on the PC board from tarnishing. First, the contacts and all places where one must solder during assembly will have to be masked with patches of masking tape. Then all parts are sprayed with several coats of a clear plastic lacquer. Before the final assembly, the setscrews 9 are prepared. Knurled discs of exactly the correct size in a handsome copper-nickel alloy are available from the U.S. Mint for the price of 10 cents each. To drill a hole through the center of the dime, however, and to solder the 2-56 screw in place, might be the most difficult task of the construction project.

Using a larger drill bit or a sharp knife, one removes a ring-shaped section of the foil around holes "U" and "V" on both sides of part 6 and on parts 4a and 4b. This prevents the screws from shorting out the foil on the parts. These foil surfaces on part 6 will be connected to the dot and dash terminals of the keyer by lengths of wire which are soldered to the foil at the rear end of part 6. The negative supply voltage, $-V_{ss}$, will be connected to the foil surfaces of parts 4a and 4b which face part 6. This arrangement has the effect that the foil surfaces of parts 4, which, for rf, shield the dot and dash contacts and, thus, reduce the effect of stray rf fields. The connection to the foil of parts 4 can be made by inserting a U-shaped strip of copper foil between parts 4 and 2, which connects both parts 4, and then soldering the $-V_{ss}$ connection to this foil.

All parts can now be stacked as shown in Fig. 2 and, after checking that the contacts line up properly, the compression nuts and screws can be tightened. The thumbscrew inserted through nut 15 should pass through

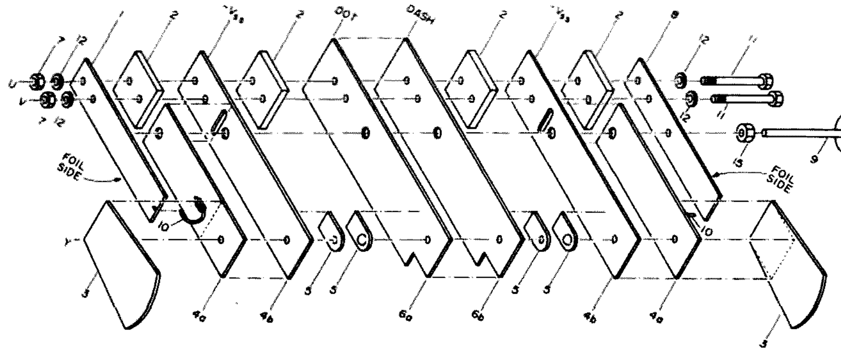

Fig. 2. This "explosion drawing" shows how the many parts fit together.

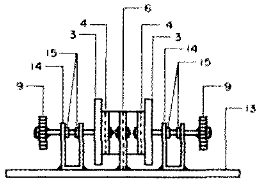

Fig. 3. Front view of the key.

Parts List

Part Number	Description
1	Spring, PC board. See Fig.1.
2	Spacers, 1/16" plastic. Four needed. See Fig. 1.
3	Paddle, 1/8" plastic or wood. Two needed. See Fig. 1.
4a, b	Lever parts, PC board. Two needed. See Fig. 1.
5	Pieces of contact springs with contact rivet, approximately 1/2" long, cut from surplus relay. Four needed.
6a, b	Center part, PC board. See Fig. 1 and assembly instructions.
7	Nuts, 4-40. Two needed.
8	Spring, PC board. See Fig. 1
9	Screw, 2-56 × 3/4" with thumbscrew head made from dime with hole drilled through center and soldered to screw. Three needed.
10	Stranded copper wire or fine braid. Two pieces about 3/4" long needed.
11	Screw 4-40 × 3/4". Two needed.
12	No. 4 washer. Four needed.
13	Base plate, PC board, 2" × 4".
14	Metal strip, brass or tinplate cut from can. See Figs. 1 and 3. Two needed.
15	Nut, 2-56. Five needed.

part 6 and both parts 4 without touching, and should contact only part 1. This screw is tightened slightly until parts 1 and 8 begin to spread. Then the linkages 10 are cut to length and soldered to parts 1 and 8.

Next, the brackets 14 (Fig. 3) for the stop-screws have to be prepared. They are bent according to the dotted lines in Fig. 1, and the locations for the holes are marked so that they line up with the centerline of part 6 when the brackets are soldered to the ground plate. The holes are drilled, and two No. 2 nuts are soldered to the inside of the brackets. With the thumbscrew inserted, the brackets are then soldered to the ground plate in such a way that the setscrews can touch parts 4 without rubbing against parts 3 and 1, or 8, respectively.

Fig. 3 shows the key as viewed from the paddles. This completes the assembly of the key. The ground plate is mounted to some suitable base, either alone or together with the keyer as shown in the photo. The contact clearance can be adjusted separately by the thumbscrews in the U-shaped brackets. If these screws tend to turn on their own, unscrew them from one of the nuts, spread the bracket slightly, and turn the screws back in against the force of the bracket, which acts as a brake. The stiffness of the paddles can be controlled with the screw that spreads parts 1 and 8.

One word of warning for operators who are used to Vibroplex-type semiautomatic keys: The MINI-MOUSE key works best with little contact clearance and minimal stiffness of the paddles, a characteristic it has in common with the FYO-key (now sold by HAL Communications Corporation). If the key is hit hard, as you would do with a Vibroplex key, you can get contact bounce and erroneous code elements. Once you are used to the different feel, however, you can operate the key with nothing more than a very slight finger movement, and you will find that the MINI-MOUSE key, together with the MINI-MOS keyer, greatly reduces operator fatigue and keying errors. ■

One Step Further

—PTTR instead of PTT

If you can push to talk, you can push to receive.

There are some amateurs who prefer a leisurely style of operating, even while mobile, instead of machine-gun-like exchanges. In such a case, the old push-to-talk button on a microphone can become a bit of a nuisance to hold down. VOX operation is, of course, a solution, but then, if one pauses to think a bit, the VOX relay will drop out. To hold relays in, one can produce a bunch of "aah"s, but it hardly makes for a pleasant sound.

A better solution was found years ago in the use of latching relays. These relays close (or open) when they are momentarily energized and then perform the opposite operation when they are again momentarily energized. So one achieves a push-to-talk and push-to-receive mode of operation where both "pushes" are just momentary depressions of the microphone button.

All it takes is some simple IC circuitry which can be used with any transceiver to provide push-to-talk, push-to-receive operation. The circuits are made up of low-cost, readily available ICs which I had on hand. Undoubtedly, the circuitry can be made even more simple by those who like to optimize IC circuitry.

The basic solid-state replacement circuit for the old latching relay is shown in Fig. 1. In this case, it is one half of a dual J-K flip-flop IC. The circuit is wired so that each time pin 1 is momentarily grounded, the outputs of pins 14 and 15 change state. Once "set," they hold their state until pin 1 is momentarily grounded again. Pin 15 is shown driving a transistor switch which, in turn, operates a relay. The transistor switch and relay are only necessary if one wants to build the unit so it is universally usable with any transceiver. In a great many cases, the transistor switch and relay may not be necessary. Depending on the voltage present on the PTT line in a given transceiver, it is often possible to tie pin 14 or 15 directly to the PTT line or to use just the transistor switch without the relay.

The 1k resistor and the switch are shown in dotted lines in Fig. 1 because, although theoretically the circuit should be complete as shown, it would prove to be erratic in actual operation. This is due to the fact that the PTT switch exhibits contact bounce. The effect of this bounce is shown in Fig. 2. Both on "make" and "break," the switch will actually cycle on and off for several milliseconds before it comes to rest in its final state. The J-K flip-flop would try to follow these switch changes, and the final outcome would be a random switching action.

Two simple "debouncing" circuits are shown in Fig. 3. These circuits will present positive switching action to the J-K flip-flop, although the switches which activate them exhibit contact bounce.

The circuit of Fig. 3 is extremely simple, has a very positive response, and utilizes a simple 7400 IC. Its disadvantage is that it requires an SPDT-type PTT switch. The leaf-spring switches in many mobile-type microphones do have the necessary contacts and an extra conductor in the microphone cord. So, in this case, the circuit can be easily implemented.

If only a simple PTT switch is available, the circuit of Fig. 3 can be used. In this case, one section of the 7414 is used as a Schmitt trigger. The resistor and capacitor form a time constant that lasts slightly longer than the duration of the contact

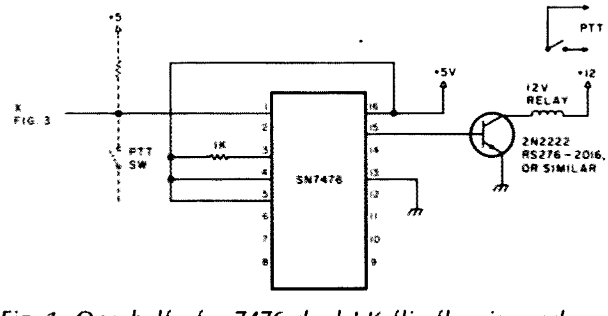

Fig. 1. One half of a 7476 dual J-K flip-flop is used as a latching circuit.

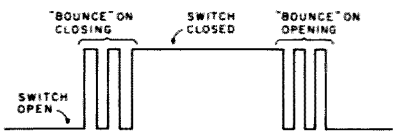

Fig. 2. An illustration of the contact bounce which occurs to some degree with any mechanical switch.

bounce from the switch. Although the values shown should suffice, if the action is not positive with any given PTT switch, one might try lowering the resistance value or using a larger size capacitor.

Depending on the number of conductors available in the microphone cord, it might be possible to place the necessary circuitry in the microphone case. If not, the circuit can be assembled on a piece of small perforated board stock. Simple point-to-point wiring can be used since there is nothing critical about the layout of the components. The voltages to the ICs need not be regulated. The required 5 volts can be obtained by using a series 200-Ohm trim-type potentiometer from a 12-volt source. Adjust the potentiometer from its maximum value until 5 volts is measured at pin 16 on the 7476 IC.

There are two ancillary circuits that one might want to consider. Probably the most important is some positive indicator that the transceiver has been placed in the transmit mode, if this does not already exist on a given transceiver. If the receiver is squelched, there is the danger that one might not notice that the transceiver has been left in, or accidentally placed in, the transmit mode. Any sort of positive indicator will do, such as a lamp operated from some line or circuit that is active during transmit. A nice touch, if one has the necessary conductor available in the microphone cord, is an LED indicator in the microphone case itself.

One might wish to add a bypass switch to the circuit so one can go back to ordinary PTT operation. It is not really necessary, however, since the push-to-talk, push-to-receive circuitry can be activated just as fast as one can momentarily depress the PTT button. But, there might be some circumstances when one is making a particularly long series of very short communications exchanges where the push-to-talk, push-to-receive operation can become tiresome.

The current drawn by the circuitry will be that typical for TTL logic devices. For small handheld transceivers, this current could be a good fraction of that drawn by the transceiver itself in a squelched receive condition. So, one would have to weigh the advantage of putting the circuitry in such a unit against the increased current drain. Of course, for mobile and home station transceivers, the increased current drain should be insignificant as far as the operation of a transceiver is concerned. ■

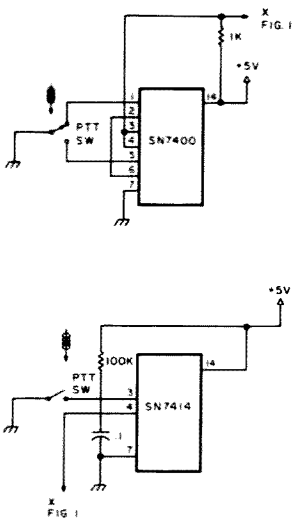

Fig. 3. Two circuits which can be used before the circuit of Fig. 1 to eliminate the effects of contact bounce.

Hooray for LC Filters!

—simplest is sometimes best

Design a simple filter and a useful control circuit to go with it.

Howard L. Ogushwitz
19 Storrs Heights Road
Storrs CT 06268

With names like Chebyshev, Butterworth, M-Derived, Maximally Flat, or Minimum Ripple, it is sometimes difficult to decide just how to pick a filter, particularly one that will pass or reject a small band of low frequencies. Well, why not use an LC circuit, since it is quite stable and simple to make?

The difficulty with the tuned LC circuit, of course, is that it is usually too sharp to pass or stop a band of frequencies, and has to be loaded (resistively) to reduce the Q. Fig. 1 shows the series (a) and parallel (b) forms of this circuit, along with a generalized impedance curve (c), which shows how the impedance of the circuit changes with frequency and Q.

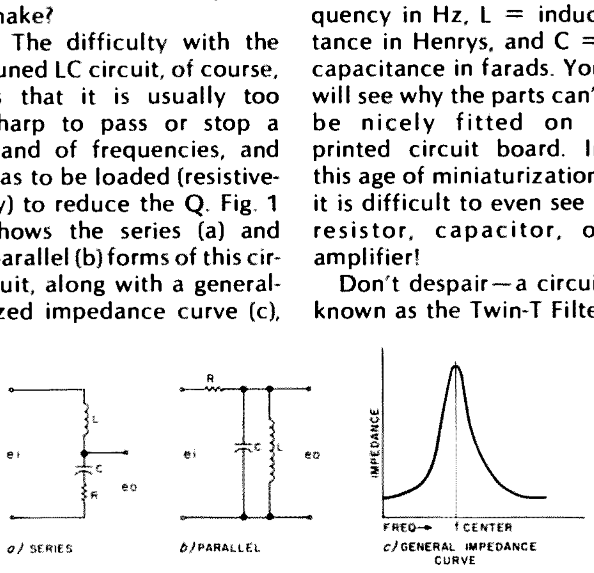

Fig. 1. Series (a) and parallel (b) tuned circuits with generalized impedance curve (c).

Another problem with this network is that as the notch or center frequency of the band of frequencies we would like to pass or stop is lowered, the necessary values of L and C become very large. Just calculate, for a center frequency of 160 Hz, the values of L and C for a series-tuned LC circuit using the following formula: $f = 1/2\pi\sqrt{LC}$, where f = frequency in Hz, L = inductance in Henrys, and C = capacitance in farads. You will see why the parts can't be nicely fitted on a printed circuit board. In this age of miniaturization, it is difficult to even see a resistor, capacitor, or amplifier!

Don't despair—a circuit known as the Twin-T Filter will not only fit on the board, but is extremely simple to design. The circuit layout is shown in Fig. 2.

All you have to know in order to design this network to "stop" or at least attenuate a particular frequency is the following set of relations: C1 = 2C2, R1 = 2R2, and $f = 1/2\pi R1C2$. For example, suppose we want to design the filter to have a center frequency of 160 Hz. By rewriting $f = 1/2\pi R1C2$ as $R1C2 = 1/2\pi f$, we find R1C2 = 1/6.28(160) = 0.000995. Since there are an infinite number of ways to multiply R1 and C2 in order to get the value 0.000995, we have to narrow things down a bit. A simple way to do this is to pick a large value for C that is available in a small physical size, such as a high K (dielectric constant) ceramic-type capacitor. Let's try .01 microfarads ($.01 \times 10^{-6}$ farads). Using this value, we find that $R1 = 9.95 \times 10^{-4}/.01 \times 10^{-6} = 9.95 \times 10^{2}/.01 = 9.95 \times 10^{4} \approx$ 100k Ohms.

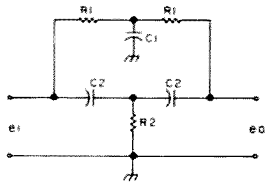
Therefore, with C2 = .01 uF, then C1 = 2C2 = .02 uF and R2 = R1/2 = 50k Ohms. Using these values, with small ceramic capacitors and 1/4-Watt resistors, we can produce a filter that will pass all frequencies except those directly around the center frequency of 160 Hz. This is a notch filter.

Let's assume that we want to stop all frequencies, but we would like to pass the frequency of 160 Hz. The op amp circuit outlined in Fig. 3 does this with good stability.

This is a negative feedback circuit, which means that the output of the amplifier is added to the input such that the input to the amplifier is reduced. The amount of feedback is controlled by the feedback network, which in our case is the Twin-T filter. Since this network passes all frequencies except a small band of frequencies around the design center (160 Hz), the feedback is large at all these frequencies, and the input to the amplifier will, therefore, be very small. This means that the output will be very low. In the region of 160 Hz the feedback is almost zero, so the output becomes large.

In other words, if we attach an audio oscillator to the input of this circuit, and slowly increase the frequency starting at about 10

Hz, we will get no output until the dial reads from about 130 to about 190 Hz, with the signal peaking at 160 Hz. As the frequency is increased further, the output will again drop to zero.



2. Twin-T filter schematic diagram.

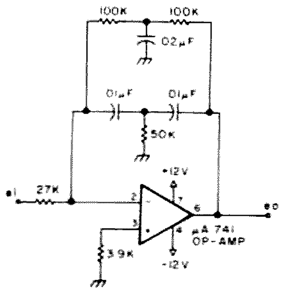


Fig. 3. 160-Hz bandpass filter schematic diagram.

This is similar to the general tuning curve of the LC circuit shown in Fig. 1(c).

This circuit was used in a tone-operated slide viewer that a friend asked me to build for him. The tape recorder that he used to provide the narrative for each slide, as it was shown by the projector, contained a tone of 160 Hz which occurred at the end of each narration. A microphone near the speaker picked up the tone, which was then amplified, and this operated a relay which caused the slide mechanism to insert a new slide. This circuit is shown in Fig. 4, and it should be self-explanatory. With a little ingenuity, many uses can be devised for this simple filter.■

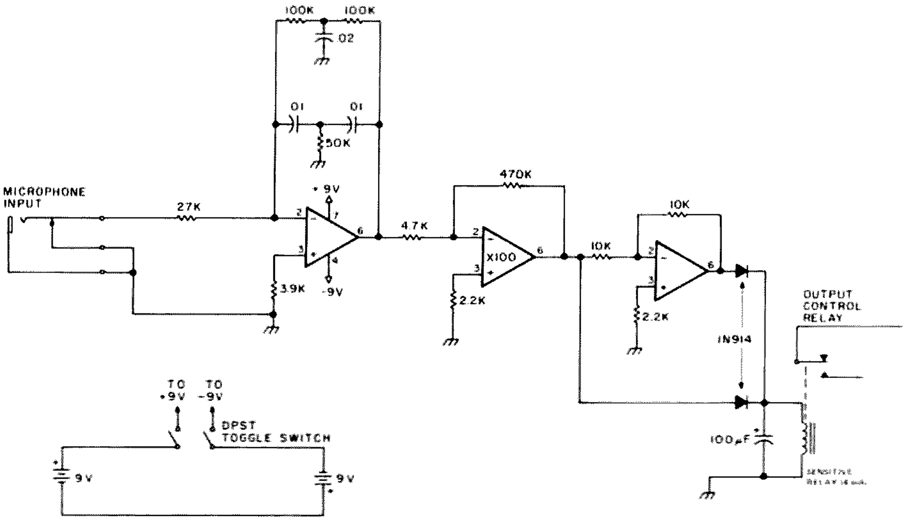

Fig. 4. Automatic slide-advance system using a 160-Hz Twin-T filter for cueing from a tape recorder speaker.

from page 55

and unless some decision is made soon by the Iraqi officials, that may be the end result.

HB9MX reports that he hit bedrock in the mountain of Clipperton QSLs and is now answering QSLs as they come in. As of the end of September, he had answered 19,298 QSLs. 15,812 were returned direct by air mail, with the remainder going via the various bureaus. 852 cards were rejected because they were not in the log. If you still don't have your Clipperton QSL, you can now get an immediate response from Kurt Bindschedler, Strahleggweg 28, 8400 Winterthur, Switzerland.

Australian Novices, recognizable by the letter N immediately following their district number in their callsign, are allowed to run ten Watts on CW and thirty Watts on SSB. They operate in the following subbands: 28100-28550, 21125-21150, and 3525-3625 on CW, and 28100-28600, 21150-21200, and 3525-3625 on SSB.

9V1TT is apparently the only XYL active in Singapore. She is the XYL of 9V1TP.

Ownership of Abu Ail, once considered unclaimed, seems to be a bone of contention between France and Djibouti. If it is owned by Djibouti, then it is just another offshore island. But if Abu Ail belongs to France, then it would be a separate DXCC country.

FH8CY should become a bit more available now that the Northern California DX Foundation has donated an FT-101 and outboard vfo. This was the rig used by K5YY on his recent African swing.

The efforts of the Northern California DX Foundation have put many new ones in the pockets of the deserving DXers. Drop them a line at PO Box 717, Oakland CA 94604, to see how you can get in on the fun.

DJ9ZB is publishing a large, plastic-bound QSL book which lists a large number of QSL Managers. It contains some 50 pages of listings, and is a great aid for the serious DXer. Order from DJ9ZB, Carl-Kistner Str. 19, D-7800 Freiburg, West Germany.

If you still need cards from the SV0WZ stay on Rhodes, try WB3JRL.

Well, that about covers the DX front for this month. We want to again thank the *West Coast DX Bulletin*, the *LIDXA Bulletin*, and *WorldRadio News* for much of the preceding information. We also want to thank all you readers who have sent reports and photos. Keep them coming, and we will see you again next month.

Ham Help

This letter is in regard to the article "Rejuvenate A Pawnee," in the October, 1978, issue. I liked the way K4GRT and W4IEV laid out the modifications and diagrams—even I could follow them. I would like to know if someone else will do the same sort of article on the Hallicrafters SR-42 2 meter AM rig, as that is what I have and I would like to put it on 2 meter FM.

If an article is not possible, is it possible that someone would modify it for me at a reasonable price? Thanks.

Wilbert R. Farris N5ADL

Denham Springs LA 70726

Corrections

Please note the following corrections to my article "The Klassic Kilowatt," which appeared in the November, 1978, issue: On page 226, column 2, line 9, should read: "3 dB weaker than a large,". On page 228, column 2, line 17 should read: "output power is 700 Watts." (It is assumed that the reader realizes that the amplifier is loaded into a dummy load for these measurements.) On page 229, column 1, lines 12 through 14, should read: "are 1500 volts at 700 mA on 20 meters, producing 700 Watts output." (This power was measured using a Drake W4 wattmeter while feeding a nonradiating dummy load.)

Dave Ingram K4TWJ
Birmingham AL

turned off. C2 charges positive through D1 until U1A switches negative once again. The period that C2 is charging positive is the space, and, at the end of the space, the circuit stabilizes unless another dot or dash is triggered.

The speed control provides biasing for U1A (note that this bias is different during a character than during a space because R9 is tied to the output of U1A). R4 determines how fast C2 charges positive during the production of a space following a character. If R17 and R20 are adjusted to make dashes equal to 3 spaces and dots equal to 1 space, then this weight will be true at any speed.

Capacitors are used liberally to bypass rf energy so that there is no interference from the transmitter. Care must be taken to ground the keyer, or problems might still arise with rf feedback, especially at high power levels.

I have been using this keyer for several years and find it very enjoyable. Keying is effortless and is ideal for extended operation such as during contests. This mechanism should also be useful to persons with certain types of handicaps that restrict motion. A 9-volt transistor battery will power the keyer for a long time and makes portable operation practical. With mechanical paddles as expensive as they are, this keyer provides an excellent alternative because it can be built complete with keying mechanism for less than most paddles on the market. Information and PC boards are available from the author. I would like to express my appreciation to Bruce Robinson and John Coken, fellow students at Temple University, for help in preparing this article.■

SOS! Ship in Trouble!

—life and death on 20 meters

When a ship sinks in the Caribbean, it's the U.S. Coast Guard and Air Force to the rescue.

John M. Murray W1BNN
4 Kenwood Circle
Bloomfield CT 06002

Imagine listening in on a real SOS situation involving a ship sinking at sea! Purely by chance, I tuned in on just such an urgent drama in August, 1977, on 20 meters.

With no fanfare, suddenly there was a loud voice at about 14.252 kHz. "This is the U.S. Coast Guard at Portsmouth, Virginia. Emergency . . . Emergency! A clear frequency is requested. A ship has been reported by an amateur operator as sinking in the Caribbean. HP3422—do you read me?"

Of all times for it to happen, my tape recorder was out of order. I could only listen and try to remember, jotting down a few notes.

"HP3422—this is the U.S. Coast Guard. Do you read me?"

Smack on frequency but weakly came the reply, "Yes, here's HP3422. We're sinking. Eleven feet of water in the hold. Thirteen persons aboard. This is a ham operator on the bridge with battery power. Ship's transmitter and electrical power gone. We have 11 life preservers. Again, 13 of us aboard. . ."

"What is your position? Give us your coordinates so we can notify Homestead Air Force Base in Florida. A rescue plane can be sent out, if it's within their range."

"Thank you. It will have to be fast. The captain says we have maybe an hour and a half before going down."

"Roger. This is Portsmouth Coast Guard. Stand by!"

"Hello, HP3422," came another loud voice, "this is Potomac Coast Guard at Washington, D.C. We have notified Homestead Air Force Base in Florida to ready a rescue plane to proceed to your position when we know it. What is your position?"

"The Captain says we're about 17-15 north, 78-58 west, but there may be a discrepancy because the last time we plotted our position was the day before yesterday, and we believe our compass is faulty." He repeated the position coordinates several times at CG request.

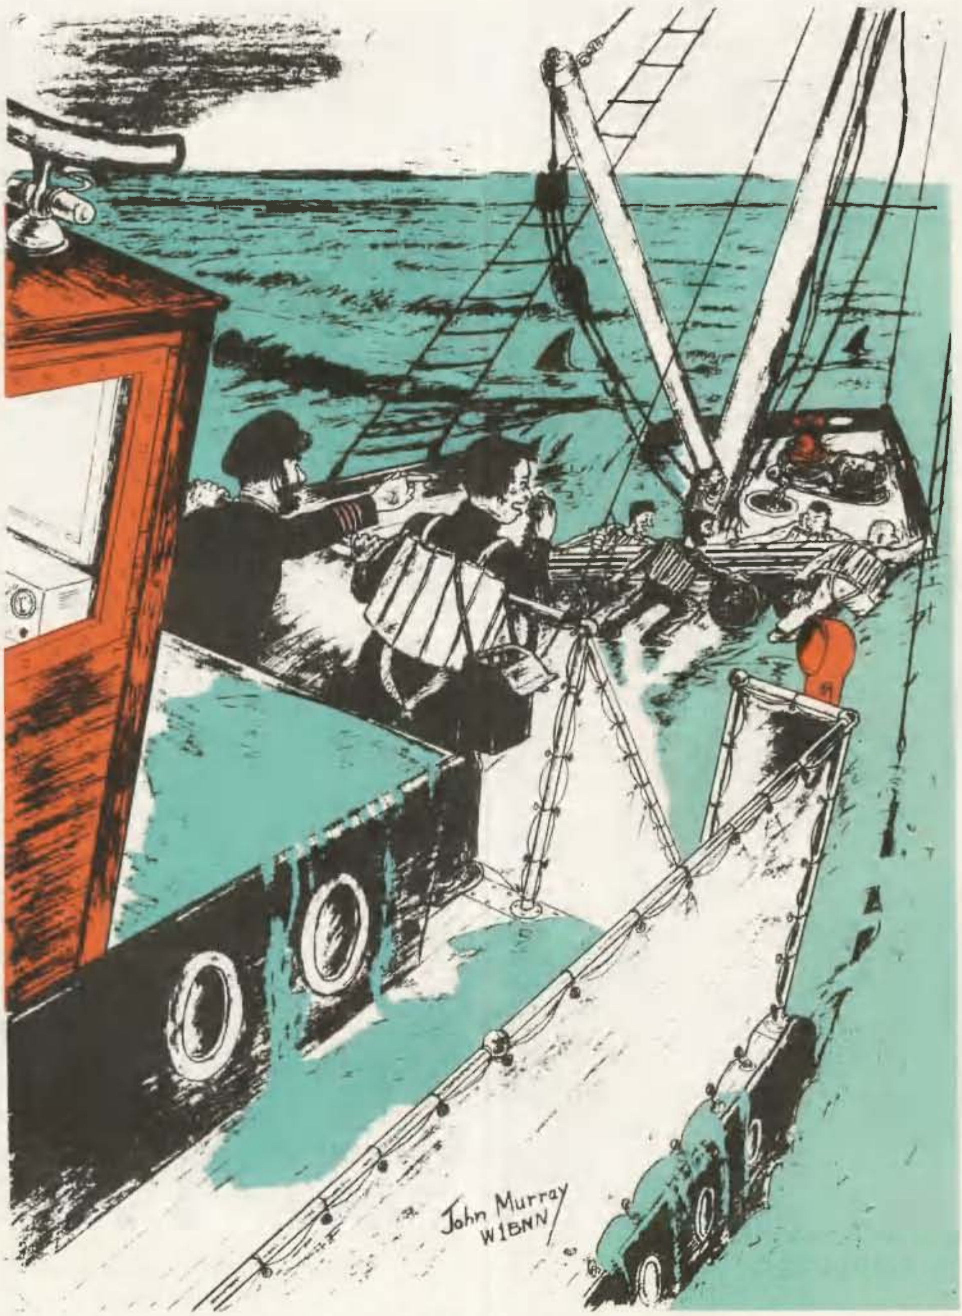
HP3422's signal had dropped way down at this point, probably due to atmospherics. The time was approximately 10:50 am, DST. As could be expected about that moment, with things getting more urgent, a bland voice cut in, "CQ twenty . . . calling twenty for Hoboken, New Jersey. This is WA5 Bing-Bang-Boom (or something like that). Is anyone around there?"

Fortunately, the directional CQ went on for only a few moments, and was quickly followed by the Portsmouth Coast Guard again: "Please QSY off this frequency immediately. This is the U.S. Coast Guard in emergency contact. A clear frequency is requested!"

Again the WA5: "What is the emergency? This is an amateur band."

The CG operator was in no mood to argue. "Please do as I say." He then continued, "HP3422, please give me your vessel's name and type. What other lifesaving gear have you aboard?" The CG signal was enormously strong and would probably override any ham competition. As he stood by, HP3422's very weak signal, fading in and out, was again audible. "Name is *Hippopotamus,* registered in Panama. Cargo vessel, about 200 feet. We're in ballast now. Grey, with much rust." The signal then stopped abruptly.

As close as I could figure it with the National Geographic Mercator Chart and an 18-inch globe, Homestead to the disaster area would be a flight of



some 775 miles, allowing a deviation eastward through the Windward Passage between the eastern end of Cuba and the tip of Haiti. Otherwise, to take the direct Great Circle route would churn up quite a bit of air space over Cuba, possibly blowing sparks from an angry cigar and setting a beard on fire. The ship was foundering in 3,000 feet of shark-infested ocean about 75 miles due south of Cap Carcasse, Haiti.

"This is Air Force rescue plane. I repeat—what lifesaving gear do you have aboard? What color are your life preservers?"

"Hello, Air Force rescue plane. This is HP3422. Thank you for calling." I could hear some other voices in the background of HP3422's signal, one yelling, "This is the captain speaking. All we have is a life raft of planks lashed to four oil drums."

At times there were considerable time lags between transmissions. Well over an hour sped by. Presumably, military direction finders and radar were being used, but so far no mention of them had been made over the air. Also, there was no explanation of how the ship got in such dire straits. No storm reports were given, nor word about why they didn't have at least one lifeboat.

Another voice cut in: "This is Homestead to HP3422. Please give us a long count so we can get a better DF bearing on you. Repeat it several times. OK?"

HP3422 proceeded to give several long counts, then stood by with, "Is that enough? Did you get a reading? Our bow is dropping deeper!"

Before the plane could answer, a new signal appeared on frequency. "This is experimental research ship *Aquarius*. We're some 300 miles from HP3422's approximate position. Can we be of help?"

"Air Force Rescue here. Negative. You're too far away. Thank you. Stand by. HP3422, I say again, what color are your life preservers and oil drums? Over."

"This is HP3422. Preservers, planks, and drums are grey."

"That'll be hard to see. Visibility is very poor, less than a mile at my altitude. I hope I can find you. This is going to be a tough one."

Homestead then gave the rescue plane a DF bearing which altered his course only slightly. Apparently, the sinking ship's position report was not as faulty as had been implied.

Suddenly, HP3422 was on the air again weakly. "The Captain's given the order to abandon ship. Water in hold now at 14 feet. When I go over the side, I'll have to cut loose from my antenna. Visibility here not too bad, maybe three miles. Almost a cloudless sky. Hazy. Oh, yes, there's a single big thunderhead about a mile due west of us. A huge one, only one in sight. Over."

The Air Force plane's signal snapped back on. "Great! I see it . . . about five miles from me. Correcting my course immediately."

"Good! This will be my last transmission. We see your plane. Over and out."

That was the last I heard

of HP3422. But the Air Force plane resumed transmission. "Hello, Homestead. Hard to believe! I've just passed over the spot where the ship went down. Great swirl of water and quite a bit of deck debris. Much bubbling—but have spotted the raft. Will make another pass directly and drop them our rescue craft. Over to you."

That was it. A few minutes later, the plane came on again briefly, reported that his rescue raft, with first aid, food, clothing, radio, etc., had landed with a hell of a splash very close to the shipwrecked mariners. Then, to my utter frustration, the pilot made one final transmission. "OK Homestead, am switching to the military frequency for follow up instructions. Thank you, hams!" And he was gone. I had no way of knowing what that military frequency was. My transceiver was limited in that setting to the 20 meter ham band. Obviously, the rescue craft's radio would be on the new frequency.

It was not clear whether the rescue plane was sent out from Florida, or whether Homestead had notified Guantanamo or one of the NASA activities in the area. Either of the latter might have meant a much shorter flight, and may well have been what happened.

In any event, it will be of much interest to me to learn any further details which some listener, or even the military operators involved, might have on this near-disaster.

The fact that there was a happy ending seems almost certain. However, I failed to hear a single word about it on the radio or on the tube, or even see a tiny item on the subject in newspapers or magazines, let alone in our ham radio publications. ■

Minicontests
—get 'em involved!

A little local competition can be a great source of fun—and new members.

Would your amateur radio club like to have a fun activity that will attract new members? If so, challenge another club to a "minicontest." Such a contest will provide behind-the-mike and contest logging experiences for all participants.

In planning a minicontest, the time and station location should be such that the greatest number of people can observe the station in operation. (A shopping mall, a public park, or a school lobby are possibilities.) As much publicity as possible should precede the contest.

In a recent minicontest between the amateur radio clubs of the Principia College (Elsah, Illinois) and the Principia High School (St. Louis County, Missouri),[1] the following format was devised by the clubs' officers. This information was duplicated and given to the members of both clubs.

Inter-Campus QSO Party

Purpose: To create interest in amateur radio on both of our campuses and to unite the campuses in friendly competition.

Rules: Each campus will operate a portable radio station using a transceiver without a linear amplifier. The contest will be held on November 12th for a period of three hours from the first contact. Starting time will be about 11:00 am. We should encourage as many non-hams as possible to get involved.

Logs need to include the following information: Time of the QSO, call of the station worked, its operator's name, and the state of the station. The name of any unlicensed operator of our station making the contact should also be entered. Only one contact per station per band counts.

Scoring: Count one point per contact by a licensed operator, or two points if the operator is unlicensed. Each unlicensed operator will be permitted to make only five contacts. Each state worked will be used as a multiplier. After the contact points have been multiplied by the number of states, add on bonus points: 2 points when an operator communicates with his home state, and 15 points if a phone patch is completed or a message delivered to a third party.

Observations at the high school station in the November 12 contest illustrate a minicontest in action. The station was located along the route between the dormitories and the dining room. All students would be sure to see it on their way to lunch. A temporary antenna was installed on the roof. Two bamboo fishpoles taped together supported a 32-foot wire for the vertical half of the antenna. The other half of the antenna was another 32-foot wire slanting down towards the roof. The antenna was fed by 60 feet of twinlead connected to an antenna tuner. The antenna loaded beautifully on both 40 and 20 meters. The sponsor of the club, WBØVOE, supplied a Yaesu FT-101E transceiver and lumber to support the fishpoles. An "old-timer" (and long-time field day "supervisor")[2] supplied the antenna, the antenna tuner, and the two-letter call (WØVM). A sign with the station call and its phonetic equivalent, "whiskey zero victor mike," was posted where all participants and visitors could see it.

The first contact was made with the college station WA9NYN (Illinois). The second contact was made with the father of the college club's sponsor (Minnesota). The next two contacts were in Ohio and Tennessee. What a good start! Four contacts in four different states! The first 19 contacts were made on 40 meter SSB. The remaining contacts were made on 20 meter SSB. All in all, the high school club made 32 contacts in 19 states.

Nine unlicensed students made contacts under the supervision of the two licensed operators. In the middle of the contest, a much appreciated contact was made with WA2RBN, the South Queens Boys Club in New York City. The father of one of the participants was in New York City on business. This student sent a message to his dad via the hotel where he was staying. Another student from New York City also sent a message to his family.

During the QSO with the Boys Club station, one of the student operators innocently used the expression "ten four." The club's sponsor immediately took the microphone and apologized for the use of "such language." This incident provided a good opportunity to explain the differences between CB and ham radio. As one student put it, "using CB lingo in an amateur radio QSO is like wearing old patched-up blue jeans to a formal dance."

Circumstances gave the high school club what could be called an "unfair advantage" in the contest. A Missouri QSO contest was on at the time, and "CQ contest, WØVM, St. Louis, Missouri" brought many answers. The two-letter call also helped. Although the high school club made more points than the college club, both clubs really won. All participants (some of whom were YLs) had fun, and each club has new members as a result of the minicontest. One of the new high school members has taken the Novice examination and is eagerly waiting for his license to arrive. When Field Day comes around in June, these two clubs are planning to join forces and enter a class 1-A station in the "big contest."

Your amateur radio club could benefit from a minicontest. Why not challenge another club, have a minicontest, and enjoy the fun? ■

Are Your Op Amps Opping?

—try this IC helpmate

Here are two small shack helpmates, simple and inexpensive, but very handy. The first one has been around in many forms. Fig. 1 shows it is an astable multivibrator that will blink the LED about one flash per second if a mini-DIP op amp with typical 741 pinouts is plugged into the socket. The self-contained nine-volt batteries should give shelf life, as the drain is both minimal and infrequent. Some of the similar pinout units are the 301, 307, 318, and 844.

A second unit was constructed to allow testing of dual units in mini-DIP packages and 14-pin units, either dual or single.

This is identical electrically but differs physically. Fourteen test point jacks are arranged around a 14-pin socket, and each socket pin is wired to one of the jacks. Five test leads with clips are brought out to connect to the proper pins, depending on the device packaging. Two of these are the plus and minus nine volts. The other three connect to points A, B, and C in the schematic of the mini-DIP tester. Simply determine where the clip leads should go according to the unit to be tested. Clip the leads to the appropriate test point jacks, and insert the IC. If the LED blinks, the device is okay. The mini-DIP version needs no battery switch. The second device only needs a switch if you believe in Murphy's law that says, "When in storage on the shelf, if two leads do touch, they will be the battery leads." ■

Major League TT Controller

—15 digits, 40 devices, 100 bucks

Now's the time for a high-performance control system.

Photos by James Sevast K3IMH

Front view of system. The system is housed in a 5" × 9" × 6" cabinet. The source selector switch selects as input the internal touchtone pad or one of two external sources. The "key" LED is turned on by a key of the pad being depressed.

The radio amateur has been using dual-tone multifrequency (DTMF) touchtone™ signalling to remotely control electrically activated devices for some time. Detection circuitry has evolved from bulky LC tone filters to phase-locked-loop tone detectors to the most recent development, an MOS/LSI integrated circuit that shrinks the size of circuitry, simplifies construction, and yields substantially improved DTMF detection performance.

Since the two meter repeater explosion started, I have had the pleasure, and occasional frustration, of building four 2 meter repeaters, three of which have limited-capability phase-locked-loop-based DTMF supervisory control circuitry. When I saw this new IC, I decided the time was right to develop a general-purpose, flexible, high-performance expandable control system that could be used at a repeater site, or in the shack, to turn

almost anything on or off remotely.

The system that has evolved can be programmed to respond to a user's access code of up to 15 digits and can control up to forty devices. Access code and control codes can easily be changed at any time by changing the system's programmable read only memories (PROMs). Cost is reasonable. Even with an empty junk box, you should be able to reproduce the system for under $100.

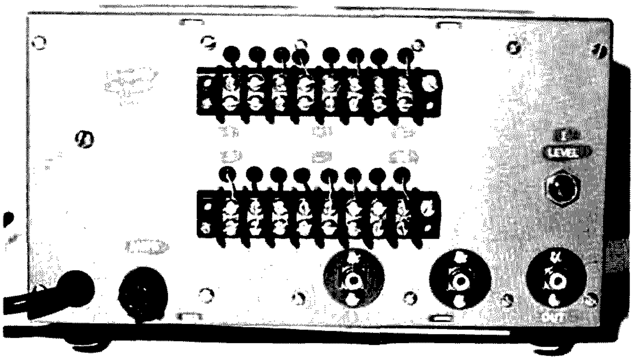
General Description

Referring to Fig. 1, audio from a receiver or other source of DTMF tones is applied to a high-tone group preprocessor and a low-tone group preprocessor. The preprocessors consist of multistage active bandpass filters that provide a minimum of 32 dB separation between the high-tone group (1209 Hz, 1336 Hz, 1477 Hz) and the low-tone group (697 Hz, 770 Hz, 852 Hz, 941 Hz). Included in the preprocessor are digital comparators that change the analog tones into digital pulse trains for input into the DTMF detector.

The DTMF detector consists of a Collins Rockwell CRC-8030 MOS/LSI integrated circuit. Fig. 2 is a block diagram of the 8030. Using a unique (patent pending) digital filter algorithm, the 8030 processes the incoming high and low tones, recognizes when a valid touchtone digit is being sent, and provides a user-selectable two-of-eight output or 4-bit binary output that identifies the digit received. High stability is assured by a crystal-controlled timebase.

The DTMF detector is followed by a sequence detector which determines if the proper access code has been received. The sequence detector, after detecting a valid access code, responds to the next digit as a command to activate or deactivate a particular control function. The sequence detector is capable of being programmed to recognize an access code consisting of as little as one digit up to a maximum of fifteen digits. It can control from one to nineteen on-off functions or up to forty pulsed functions. Circuitry for five on-off functions and one pulsed function will be described in detail.

The output interface has drivers that can power relays or other external dc circuitry. The open collector transistor outputs can sink up to 300 mA and can sustain voltages of up to 30 V dc.



Rear view of the system. Relay contacts are brought out to terminal strips for easy connection to external devices being controlled. Jacks are provided for the two input sources and audio output from the touchtone pad. A level control was included for source #1.

The status display shows if the incoming digit sequence corresponds to the access code, which digit is being received, and which

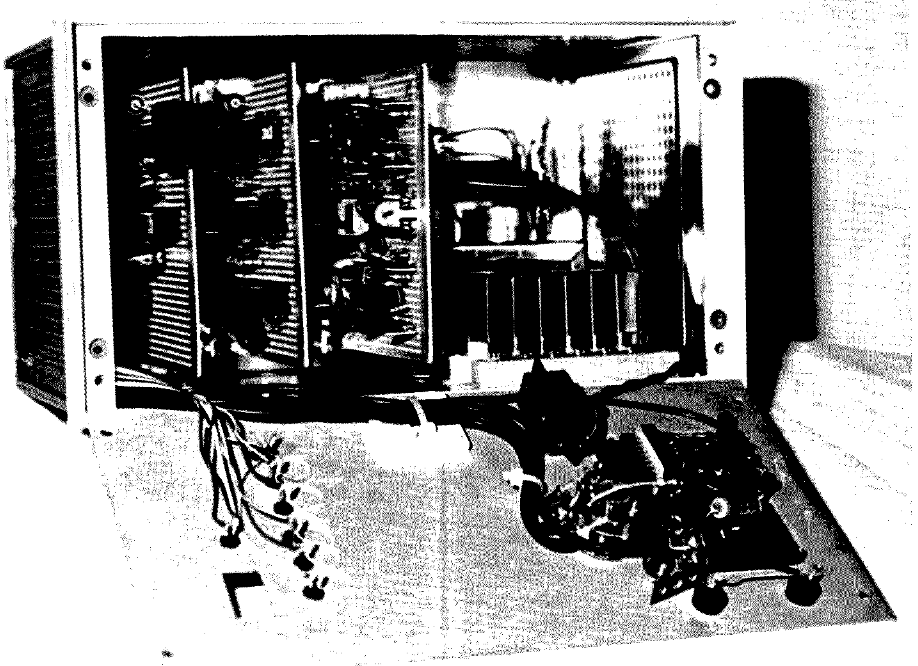
NOTE 1 (boxed: A7–A4 of access code rows)

Table 1. PROM #1 (U9) programming chart. Notes: 1 — The access code is determined by the addresses within the box. Any access code can be chosen by appropriate address selection when the PROM is programmed. Access code 2-7-0-3-1 is shown. 2 — All other PROM outputs are left unprogrammed (binary 0).



Front view with panel lowered. The three circuit cards plug into sockets attached on standoffs at the rear of the cabinet. The power supply and relays are located in the right portion of the cabinet. The cards are, right to left, the DTMF detector board, the sequence detector board, and the output interface and display driver board.

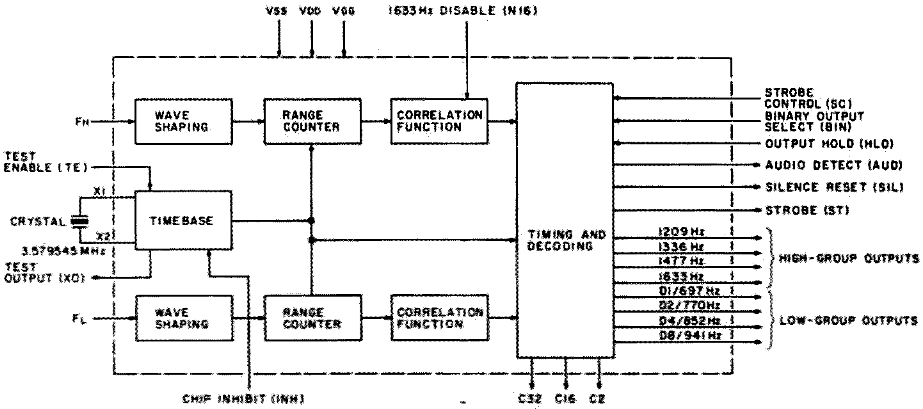


Fig. 2. CRC-8030 block diagram (from CRC-8030 data sheet, pg. 2, Fig. 3).

functions are on or off.

I elected to include an optional touchtone pad in my system for local control. When not in use for local control, the pad drives my two meter transmitter.

Tone Group Preprocessor

The tone group preprocessor circuitry is shown in Fig. 3. 100 millivolts peak-to-peak audio is coupled into the high- and low-tone group bandpass filters through gain control potentiometers. The gain control potentiometers permit individual adjustment of gain of the high-tone group and low-tone group filters to compensate for "twist," which is the term used to describe differences in the level of the high group and low group outputs from the user's receiver. The filters consist of four active bandpass stages. Trimpots are provided for each filter stage so that the stage can be tuned to the proper frequency. In addition to filtering, the active stages provide gain so that an incoming tone is amplified to 6 volts peak-to-peak at the filter output.

An LM339 comparator converts the sinusoidal output from the group filter into a digital pulse train. A trimmer potentiometer, Rc, permits adjustment of the comparator reference voltage so that the comparator output is logic low when DTMF tones are not being received. Note that mylar™ capacitors are used in the bandpass filters to minimize filter drift with temperature.

DTMF Detector

Fig. 4 shows the circuitry for the DTMF detector. The CRC-8030 has numerous inputs and outputs, which give the device great flexibility.

In this application, I have selected the binary output format rather than two of eight and thus have grounded the binary select pin, Bin. Likewise, I am using a 12-digit touchtone pad rather than a 16-digit pad and have, therefore, grounded the "1633" pin which defeats the reception of these additional control digits. The strobe control selection pin, Sc, is also grounded, which ensures that the detector only responds to high quality input signals. This reduces the probability that voice or noise signals from the receiver will cause the chip to falsely identify the presence of a control signal.

Outputs include a 4-bit binary word, a strobe signal that indicates when a valid tone pair has been received, and a silence reset signal that continually pulses when valid tone pairs are not being received.

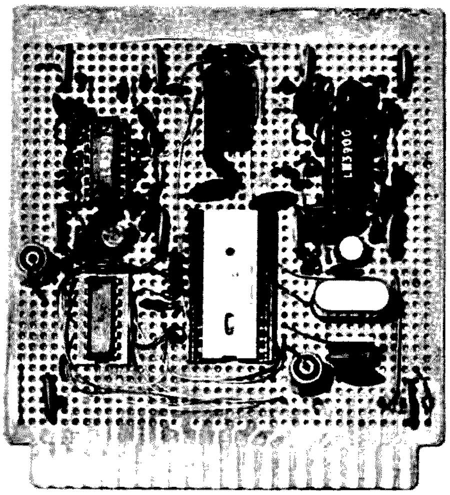
The CRC-8030 can be operated from a single or dual power supply. When operated from a single 5-volt dc power supply, as I have elected to use, the outputs are only capable of driving LPTTL or CMOS.

CD-4049 CMOS-to-TTL buffers interface the detector to the remainder of the circuitry.

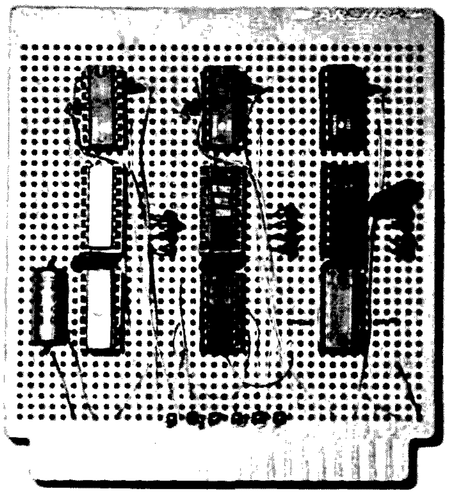
Preprocessor/Detector Construction

As can be seen in the photograph, the high- and low-tone group preprocessor circuitry and the dual-tone multifrequency detector fit nicely on a single 4" × 4½" circuit board. The preprocessor circuitry operates from a +12-volt dc power supply. I have included on the circuit board an LM340-5 voltage regulator that provides the +5 volts dc for the CRC-8030 chip.

If you are fortunate enough to have a microcomputer in your radio shack, you could utilitze this single card to convert DTMF tones into a 4-bit binary word for input to your microcomputer. Sequence decoding and control could be programmed by appropriate software. If you don't have a microcomputer, the following "computer-like" circuitry



DTMF detector circuit board.



Sequence Detector Board.

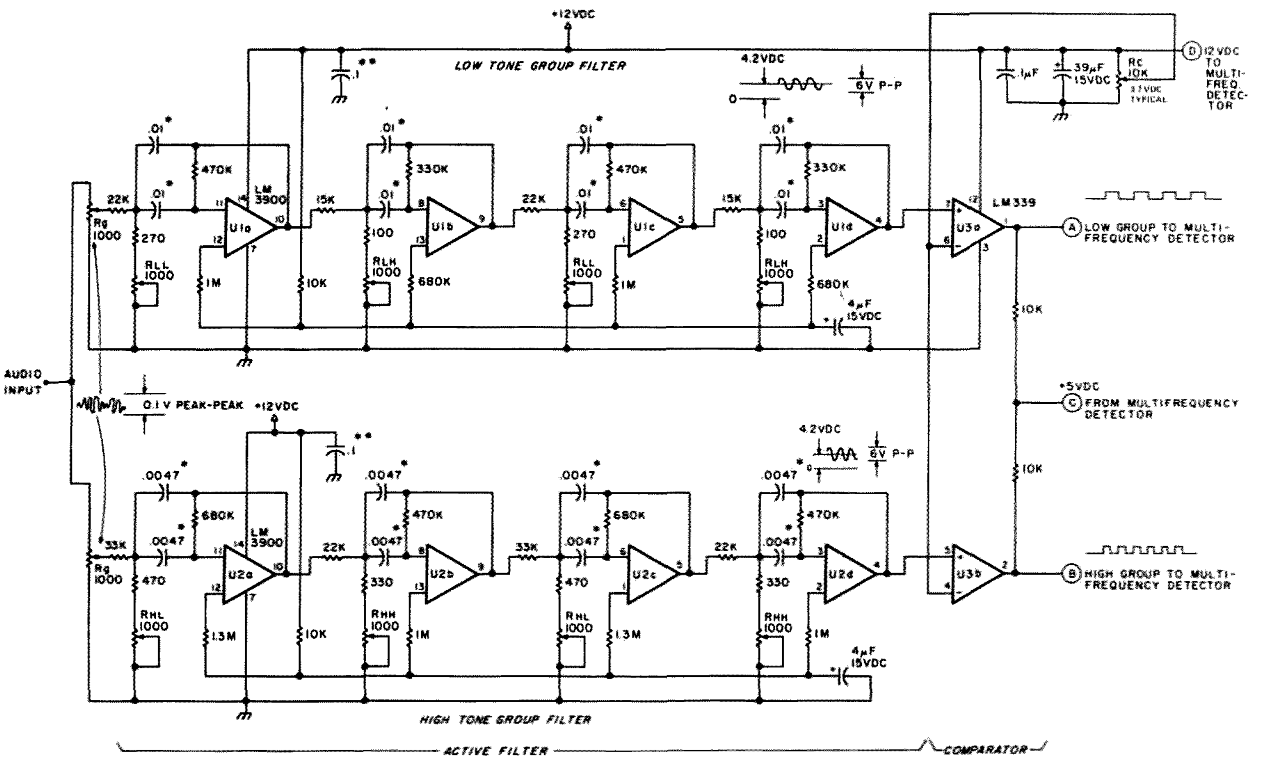


*Fig. 3. High- and low-tone group preprocessor circuitry. * Mylar TM, 10%; ** located close to associated LM3900; all resistors ¼ Watt; all capacitors uF.*

will do the job.

Sequence Detector

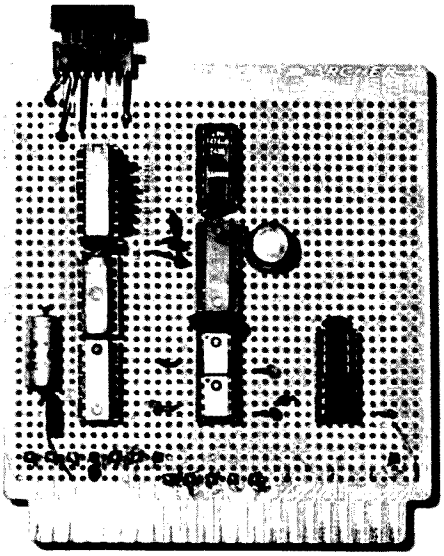
The heart of the sequence detector consists of three 4-bit by 256-word programmable read only memories (PROMs). To address the 256 words of the PROMs, an 8-bit address is required. Referring to Fig. 5, this 8-bit address is provided by a 4-bit binary counter and the 4-bit word from the DTMF detector circuitry previously described. PROM #1, combined with PROM #2 and PROM #3, provides eleven control bits that are used to activate or deactivate control functions.

Detection of a valid access code occurs as follows: Initially, the 4-bit binary counter outputs are all 0. When a digit is received by the DTMF detector, its 4-bit binary word combines with the binary counter word to produce a PROM address. One output bit of PROM #1 is called the valid sequence bit. If the digit received by the DTMF detector is the first one in the access code sequence, the PROM #1 output accessed by the 8-digit address will contain a binary 1 for the valid sequence bit. This bit causes the 4-bit binary counter to increment by one count. When the second valid sequence digit is received, its 4-bit binary word, combined with the 4-bit binary counter which is now 0001, will also address a location in PROM #1 where the valid sequence digit has been preprogrammed to logical one. In this way, the binary counter continues to increment and combine with the DTMF detector output to address different parts of PROM #1 where valid sequence bits are stored. If an invalid digit is received, it, combined with the binary counter, addresses a part of PROM #1 where the valid sequence bit was never preprogrammed to logical one and is, instead, zero. Logical zero causes the 4-bit binary counter to be reset to all zeros, thus terminating valid sequence detection.

After the proper access code has been received, the next digit received by the DTMF detector, combined with the counter circuit, addresses a location in PROM #1, #2, or #3 where a word was preprogrammed to activate an appropriate control bit.

When the control digit is received, the PROM #1 location addressed does not have the valid sequence bit set. Therefore, the 4-bit binary counter is again reset to zero and further control cannot occur unless the proper access code is again received.

Table 1 provides additional information on the programming of PROM #1. Study of this table will give you a better understanding of how the access code and control bits are programmed. For example, an access code of 2-7-0-3-1 is shown. You could use any digit combination. The access code could be fewer digits or more digits (up to 15), depending on your own individual requirements. Note that the 8 bits of the PROM address (A0-A7) are made up of a 4-bit word from a binary counter (A0-A3) and a 4-bit word from the DTMF detector (A4-A7). The binary counter portion of the address word is all zeros for the first digit, 0001 for the second digit, 0010 for the third digit, and so forth.



Output interface and display driver board.

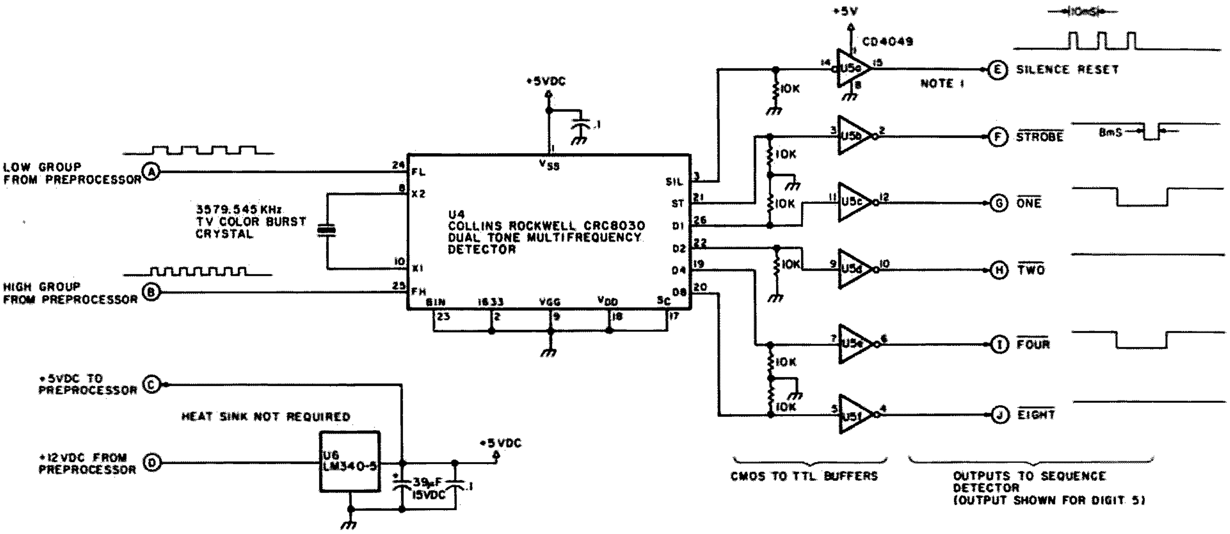


Fig. 4. Dual-tone multifrequency detector. Note 1 — buffer can drive two TTL loads maximum.

The remaining 4 bits of the address are a function of the access code as shown.

PROM #1, which initially has all of its output bits unprogrammed at zero, is programmed at the five access code addresses shown to have output bit 0_1 to be 1. The control digits represent the last digit sent in a sequence, and, therefore, the binary counter portion of the PROM address would be 0101 as shown, representing the sixth digit received. I have programmed PROM #1 to respond to the control digits 9, 0, and *. These addresses are used in the PROM programming process to set output bits 0_2, 0_3, and 0_4 to logical one as shown. Note that the output bit 0_1 (valid sequence bit) is set to 0 for these addresses, which will cause the circuitry to recognize that the end of a valid sequence has occurred.

Since 1 bit of PROM #1 is used as the valid sequence bit, only 3 bits remain to activate control functions. To have additional control functions, additional PROMs must be added. Tables 2 and 3 give the programming instructions for PROM #2 and PROM #3, respectively. Since PROM #1 contains all of the information for determining if a valid access code has occurred, the other two PROMs need only be concerned with providing additional control bit outputs. As in PROM #1, when a control digit is received, the binary counter is 0101 as shown. The remainder of the address is determined by the control digit (1, 2, 3, 4, 5, 6, 7, and 8). These addresses are the only words in PROMs #2 and #3 that have any output bits set. Since no information related to the access code is required in PROM #2 or #3, any change in the access code only requires programming one new PROM (PROM #1).

Sequence Detector Circuitry

The sequence detector circuitry is shown in Fig. 6. The six signals from the DTMF detector are further buffered by a 7404 hex inverter. This provides adequate drive to address up to 10 PROMs. The PROMs, Signetics 82S129s, were chosen for their ready availability and their low cost. The PROMs are tristate; 270-Ohm resistors from the output pins to ground ensure that the following TTL circuitry can be properly driven.

The 7493 binary counter is incremented by the trailing edge of the strobe pulse. After the incoming digit has gone away, the silence reset signal will begin to pulse and will reset the binary counter to zero if the 7474 D flip-flop is not set. The flip-flop will be set, thus disabling silence reset from resetting the binary counter, if the digit received was part of the access code. The valid sequence bit only exists for the duration of the strobe pulse. It is stretched by the 0.1 uF capacitor, 270-Ohm resistor parallel combination, so it is still present when the D flip-flop is clocked by the trailing edge of the strobe pulse. An LED connected to the $\bar{Q}$ output of the flip-flop lights if a valid sequence is being received. As long as the LED is on, the sequence is valid.

The outputs from the PROMs are pulses of duration equal to the strobe pulse. RS flip-flops consisting of 7402 NAND gates store the control instructions. For example, function 1 is activated by a 1 on PROM #3 output line 0_4. Function 1 is deactivated by a 1 on PROM #3 output line 0_3. From Table 2, you can see that this corresponds to a digit 1 setting the flip-flop and a digit 2 resetting the flip-flop. Again, these digits represent the last digit to be transmitted in a control sequence. LEDs are connected to the flip-flops to show the status of the various control functions.

Note that output 0_2 of PROM #1 is not connected to a flip-flop. The pulse that occurs on this output line is used to activate a one-shot that will be described later.

The sequence detector circuitry fits on a 4″ × 4½″ circuit board, as shown in the photograph.

The sequence detector could be used for other than DTMF applications. For example, a key pad connected to this sequence detector would make a great electronic combination lock. You would have to include in your key pad circuitry something to generate the strobe and silence reset signals and some gates to convert the 2-of-8 output that is typical of most pads to 4-bit binary.

Output Interface

The output interface is shown in Fig. 7. Functions 1 through 5 are buffered by 75452 peripheral drivers which are capable of sinking up to 300 milliamps with collector-to-emitter voltages as high as 30 volts dc. A 400-milliwatt maximum power dissipation for each transistor must be observed.

In my unit, I elected to have the transistors drive some miniature 24-volt dc relays which I had in the junk box. These relays have a set of normally-open and normally-closed contacts which give me great flexibility in interfacing; I can control both ac- and dc-operated devices. Relays have the further advantage of assuring electrical isolation of the devices being driven from the control system. If you elect to drive relays, include the 1N4002 diodes, which will keep the back EMF from the relay coil from getting back into the circuitry.

Function 6 is a pulse produced by a 74123 one-shot which I arbitrarily adjusted to provide a one-second contact closure at the output. The 100 uF capacitor connected to the 74123 can be changed in value to lengthen or shorten the contact closure time.

Status Display

Also shown in Fig. 7 is

TOUCHTONE* DIGIT	DTMF DETECTOR WORD				BINARY COUNTER				PROM OUTPUT BITS (NOTE 1) — CONTROL BITS			
	8	4	2	1	8	4	2	1				
	PROM ADDRESS (MSB)							(LSB)				
CONTROL DIGITS	A7	A6	A5	A4	A3	A2	A1	A0	O1	O2	O3	O4
5	0	1	0	1	0	1	0	1	0	0	0	1
6	0	1	1	0	0	1	0	1	0	0	1	0
7	1	1	1	1	0	1	0	1	0	1	0	0
8	1	0	0	0	0	1	0	1	1	0	0	0

Table 2. PROM #2 (U10) programming chart.

4	0	1	0	0	0	1	0	1	1	0	0	0

Table 3. PROM #3 (U11) programming chart. Note: All other PROM outputs are left unprogrammed (binary 0).

the circuitry for the MAN-7 front panel LED indicator. The MAN-7 is driven by a 7447 decoder/driver. Inputs to the decoder/driver are latched by the 7474 D flip-flops. The display circuitry is straightforward, with one exception. The 7447 normally responds to

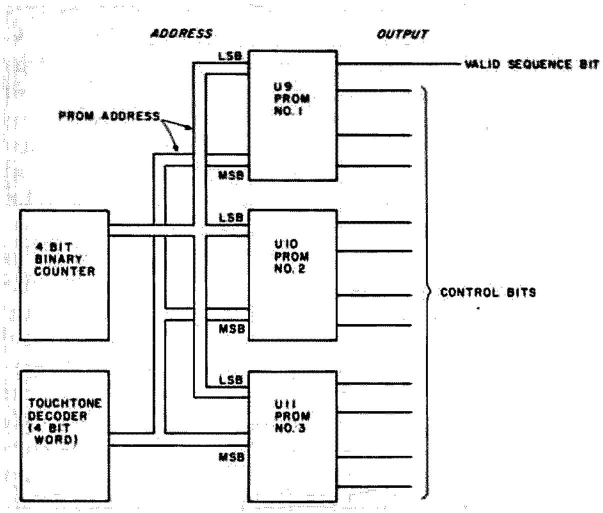

Fig. 5. PROM addressing.

all inputs at logic 0 as representing the decimal digit 0. The output of the DTMF detector for the digit 0 is binary 1010. A 7420 NAND gate decodes the presence of binary 1010 and clears the four flip-flops so that the LED display will truly represent the presence of the digit 0.

The LED display cannot represent properly the two control digits, * and #. For *, the LED display will show a small backward C. For #, the display will show a small u. All the numerical digits are displayed correctly.

The LED digit display is optional; it is not really needed for proper functioning of the system. It does allow you to see if your access code is being sent. It is also useful in determining if a user's touchtone pad is functioning properly. For example, using this display, I quickly found out that one of my touchtone pads was not transmitting the digit 6 correctly. Without it, I would have suspected the control system rather than the touchtone pad.

The output interface and status display circuitry easily fits on a 4" × 4½" circuit board, as shown in the photograph.

Power Supply

A 117-volt power supply is shown in Fig. 8. In addition to supplying voltages for the control system, it also provides necessary voltages to the PROM blast-

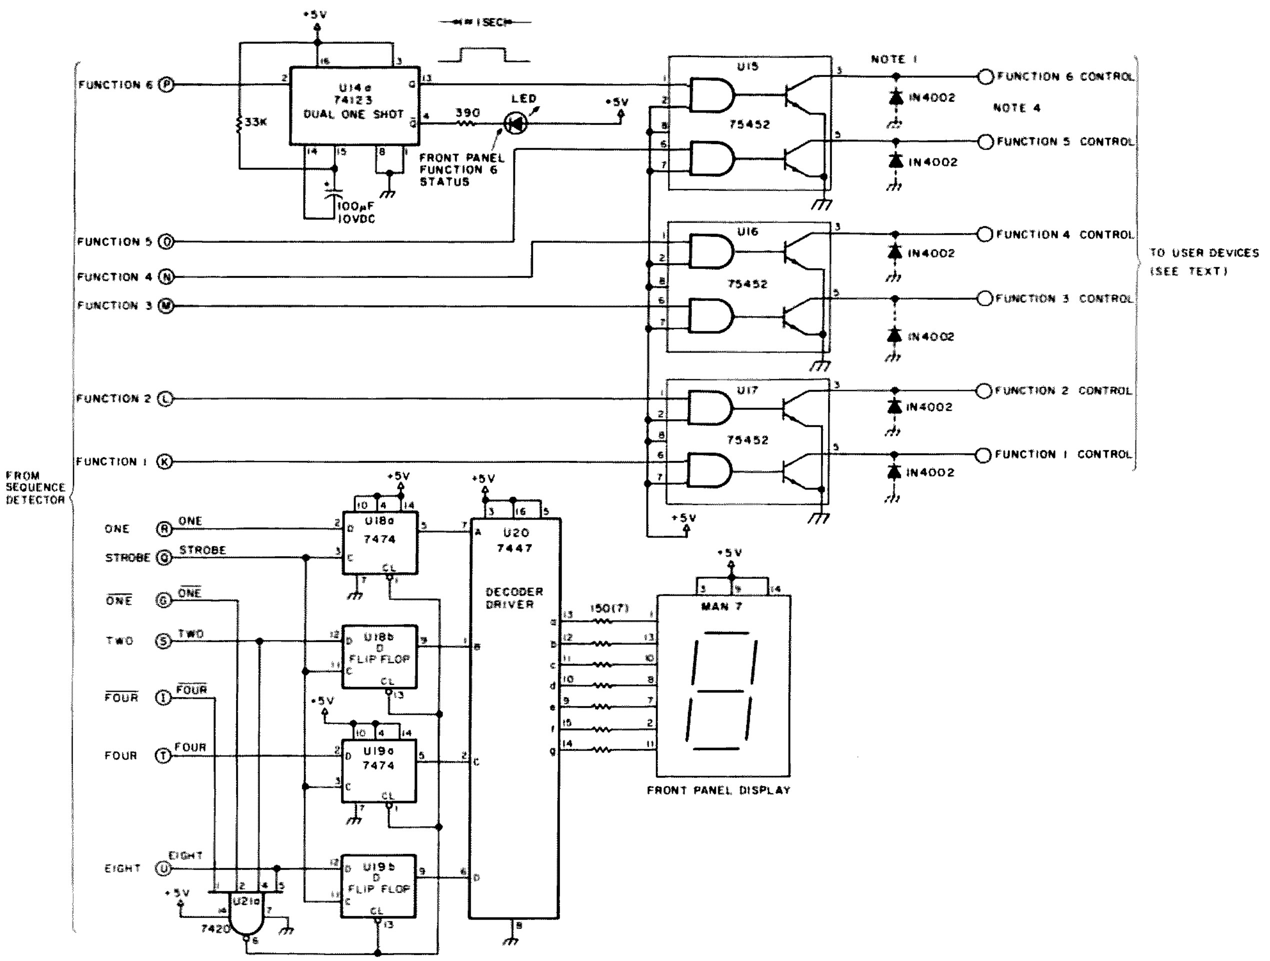

Fig. 7. Output interface and display driver circuitry. Notes: 1 — Output transistors are 30 V dc maximum voltage, 300 mA maximum current, 400 milliwatts maximum power dissipation. 2 — Bypass each IC power pin with 0.1 uF capacitor. 3 — Bypass +5 V dc input to circuit card with 39 uF, 15 V dc capacitor. 4 — Diodes are optional; required when driving inductive load such as a relay.

er (to be described shortly).

Construction

The construction is well illustrated by the photographs. The touchtone detector circuit board was wired point-to-point, whereas the other circuit boards used wire-wrapped sockets and interconnections were made by wire-wrap.

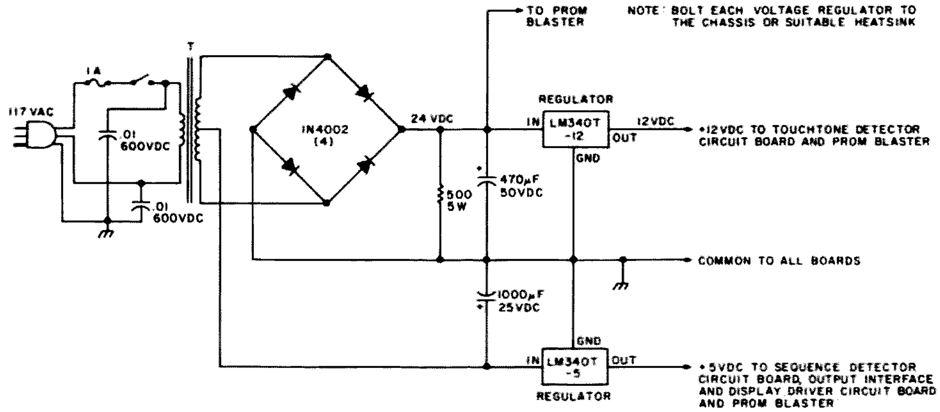

Fig. 8. Power supply. Transformer T — 117 V ac primary, 18 V ac center-tap secondary at 1 Amp minimum.

Most of the parts are readily available from distributors that advertise in this magazine. One part deserves special note. The CRC-8030 DTMF detector can be purchased from your local Hamilton Avenet Electronics distributor or can be purchased directly from Rockwell Collins, 4311 Jamboree Boulevard, Newport Beach, California 92663, Attention: Component Sales.

The CRC-8030 represents the only expensive part in this entire system, selling for $42 (plastic) as of January, 1978. While relatively expensive, it provides one heck of a lot of performance. Prices will probably drop rapidly as these chips are produced in quantity, so you should check the current price before ordering.

The PROMs can be pur-

chased from S.D. Sales, P. O. Box 28810-B, Dallas, Texas 75228. The PROMs sell for $2.50. I recommend you buy one or two additional PROMs in the event that you accidentally program one of yours incorrectly.

Programming the PROMs

Fig. 9 shows the PROM blaster circuitry. This circuitry is almost identical to that provided in the Signetics data sheet that will accompany your PROMs. I recommend that you use an oscilloscope to verify proper operation of the PROM blaster circuitry as per the waveforms shown before you begin your programming. If you don't have a scope, enlist the help of a friend who does. Programming is straightforward. Set the address switches to logic 1 or logic 0 as per Table 1, 2, or 3 to set up an address. Next, choose the correct output bit to be programmed and move its program switch to the programming position momentarily and then return it to the display position. The LED will light if the bit has been programmed. If the light does not light, then the bit still remains at logic 0 and programming of that bit has not taken place.

The electrical programming sequence is as follows: When one of the programming switches is moved from the read position to the program position, a 5-millisecond-long pulse is generated which raises the 5-volt dc power supply to pin 16 of the 82S129 to 8.75 volts dc. At the same time, a 1-millisecond delay pulse is generated, which, when it is completed, activates a 3-millisecond pulse which raises the voltage on the output bit being programmed from 0 volts to 17 volts dc. The voltage is approximate; the regulator which provides drive to the output bit being programmed is a current source which holds the programming current to 200 milliamps plus or minus 20 milliamps. The 3-millisecond pulse, in addition to raising the output voltage of the bit being programmed, triggers a 1-millisecond delay which, at its conclusion, activates a 1.5-millisecond pulse which causes the enable line, pin 14 of the 82S129, to be taken low, at which time the output bit is actually blasted. At the conclusion of the 5-millisecond time period, the enable line is again brought low, enabling the chip so that, when you return the programming switch to the read position, the status of the output line can be read by its associated LED.

When you get done programming your PROMs, mark each PROM with the proper PROM number so that you will know which socket it should be plugged into.

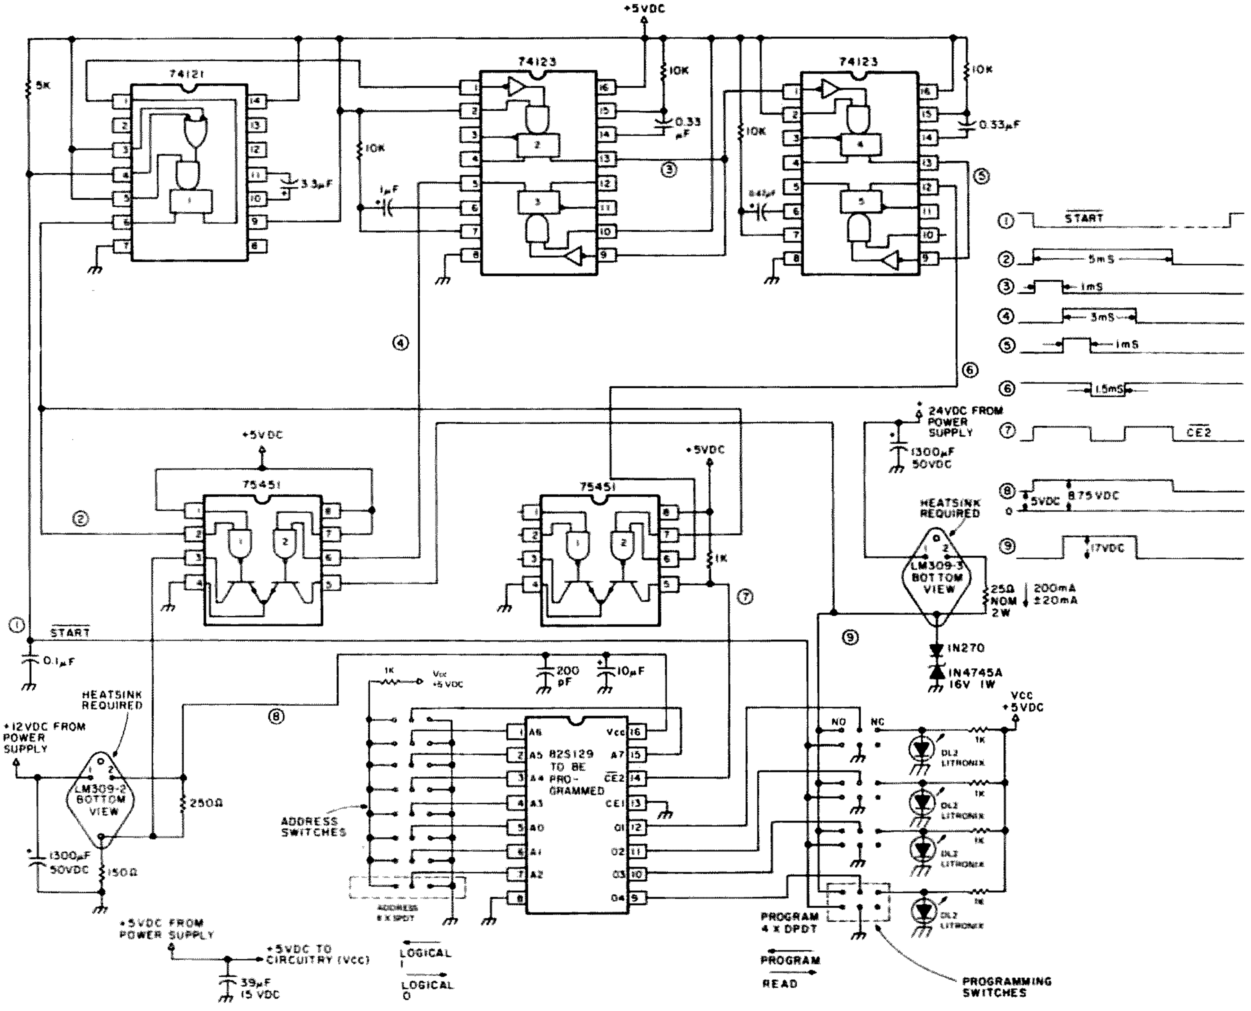

Fig. 9. PROM blaster circuitry. Notes: 1—All resistors ¼ Watt unless otherwise indicated. 2—All capacitors are uF unless otherwise indicated.

Adjustments

The only adjustment required to your touchtone control system is the alignment of the preprocessor circuitry. Refer to Fig. 3 and proceed as follows. Connect the audio input to your source of touchtone signals. Verify with an oscilloscope that the audio level at the wiper arm of the two gain pots, Rg, is 100 millivolts peak-to-peak. Beginning with the low-tone group, generate a 697-Hz tone by depressing both digits 1 and 2 on your touchtone pad. While observing the output signal at the first amplifier, U1a, on an oscilloscope, adjust R_{LL} for maximum signal. Next, move your oscilloscope to the output of U1b, generate a 941-Hz tone by depressing the digit 0 and the digit * on the touchtone pad, and adjust R_{LH} for maximum signal. Returning to the 697-Hz tone, adjust the R_{LL} associated with U1c for maximum signal at the output of U1c. Returning to the generation of the 941-Hz signal, adjust R_{LH} associated with U1d while observing the output of U1d. Repeat the adjustment sequence while observing the output at U1d. Adjust the potentiometers as necessary to get uniform response to the 697-Hz tone, the 941-Hz tone, and the two tones in between, 770 Hz and 852 Hz. If the circuitry is working properly and is properly aligned, you should observe voltage levels at the output of U1d as shown in Fig. 3.

The high-tone group filter is aligned in a similar way, with the R_{HL}s adjusted for a maximum output from the 1209-Hz tone (digits 1 and 4 held down simultaneously) and the R_{HH}s adjusted for a maximum from the 1477-Hz tone (digits 3 and 6 held down simultaneously). After alignment of the bandpass filters is completed, go back and adjust the gain pots, Rg, so that the voltages at the output of U1d and U2d are equal.

Next, using a voltmeter or an oscilloscope, adjust the voltage at the wiper arm of pot Rc to 3.7 volts dc. This should correspond to 0.5 volts dc lower than the dc voltage at the output of U1d and U2d. Next, observe the output of U3a and U3b on an oscilloscope while depressing digits on your touchtone pad. The signals observed should look very similar to square waves with timing between pulses a function of the tone frequency being received.

Extending Performance

The system can be easily extended to control more than the six functions that I have described. To do this, additional circuitry must be added and a method to address these additional control functions is required. The additional circuitry consists of adding more 82S129 PROMs, function flip-flops (7402s), and appropriate output circuitry. Each additional PROM will permit you to control two or more on-off functions or four one-shot functions. The binary counter and hex inverter that buffers the signals from the DTMF detector will drive up to 10 PROMs.

Access to these additional functions is obtained as follows: Note that the # digit on the touchtone pad has thus far not been used. Program your #1 PROM so that, when the digit # is depressed as the next digit after the access code, none of the control bits are set to logic 1, but the valid sequence bit continues to be logic 1. Now program your additional PROMs so that they will respond to the next digit received. If you want additional control digits beyond this, then program your #1 PROM so that additional control functions can be accessed by the access code followed by #, #, and then the control digit, etc.

The unused digit # can be used for other functions. For example, if each of the members of your radio club had one of these units connected to his receiver, he could have it disable his speaker unless someone dials his access code followed by the appropriate digit to turn his speaker on. However, in an emergency, you might like to activate all of the club members' speakers simultaneously. Perhaps you have chosen a 5-digit access code with the first 2 digits unique to your club and the last three digits to identify the club member. By programming the PROM that activates the speaker to also respond to the first two digits followed by the #, with # programmed to set the speaker control bit, you could activate all club members' radios by the club identification number followed by the #. Normal function of the control system would not be affected. If you understand at this point how the PROMs are programmed, you should have little trouble determining the PROM address and output bit that should be programmed to permit this capability.

Another use for the # digit might be to turn on or off all of your devices at once. In this case, you would program the PROMs so that, at the conclusion of your access code, receipt of the # would cause all of the bits of all of the PROMs that reset flip-flops to be programmed for logic 1. Again, normal operation would not be affected.

These are probably just a few of the ways that the performance of this control system can be enhanced. The use of inexpensive PROMs permits you to try all sorts of ideas without the need to rewire circuitry.

Conclusion

I have described a small, easily reproduced, flexible and extendable touchtone control system that can be used to control any electrically-activated device remotely. Performance of this device has been most gratifying. I have had it operating for several months on my two meter receiver, and I have yet to experience any false decoding. I am using a five-digit access code. The system responds reliably and rapidly to touchtone signals, with a performance that parallels what you expect of a commercial touchtone telephone.

In the last ten years, DTMF detector circuitry has evolved from LC filters to 567 phase locked loops to, now, the CRC-8030 DTMF detector. With our rapid growth in IC technology, I am sure the 8030 will someday be obsolete, but replacing it will give the semiconductor manufacturers a hard act to follow. ■

CB to 10

—part XVII: SBE and Pace rigs

Easy conversions mean happy QRP mobiling.

Larry Fletcher K3SZN
PO Box 188
Churchton MD 20733

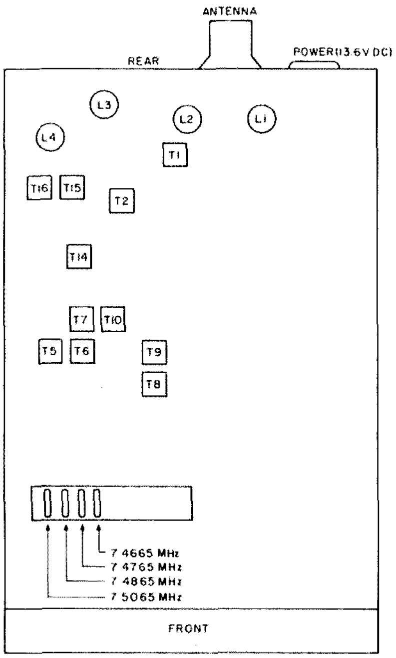

Fig. 1. SBE Sidebander III (SBE-18CB).

One of the easiest projects I have undertaken as an amateur and also one of the most rewarding has been the conversion of 23-channel CB rigs to 10 meters. I first converted an SBE "Sidebander III" a week before Christmas, 1977, and, with very little actual time on the air, worked eleven states and Europe from my car! I was hooked.

I have always found the 10 meter band to be friendly, and, although 5 Watts input power may not seem like much to some readers, it sure packs a punch in that delightful world of 28 MHz. Rather than fear the "big guys" on 10 meters, as some authors have suggested, my rig starts off at 28.510 MHz as channel 1, resulting in the bánd plan listed in Table 1. This hot little rig has performed so well that I have set myself a goal of "WAS 10 meter QRP mobile" for this year, which I have every confidence of reaching.

I have since converted, and helped others in this area to convert, AM and SSB CB rigs of various other manufacture. One thing I have learned and would like to stress here is that "conversion" from 11 to 10 meters is easy. The only parts swapping required is the change in crystals. Once the crystals have been changed, only straightforward realignment of the oscillator, mixer, and rf portions of the rig affected by the frequency change is necessary. That is, no i-f alignment or alignment of those oscillator sections using the original crystals is necessary. Furthermore, the little realignment that is required can be accomplished with the barest minimum of test equipment. I estimate that ninety percent of all

23-channel CB rigs now available can be converted using only a 12-volt power supply, a piece of wire a few feet long (2 or 3 feet suffices, used as a signal source for oscillator/receiver mixer/receiver alignment), a cheap CB wattmeter or other output power indicator, and a 5-Watt dummy load (52-Ohm resistor, 5 Watt, or less, if properly heat sinked). A frequency counter or friend with a calibrated receiver permits certain refinements regarding netting and checking SSB "clarifier" ranges once the basic tune-up has been completed.

Practical Conversion Hints

First, I recommend that anyone undertaking this project either purchase or borrow the Sams *Photofacts* covering the CB to be converted. The *Photofacts* provides a readable circuit diagram, parts locator guides, and alignment procedures which can be easily adapted to the new frequency.

Secondly, avail yourself of a good set of properly-fitting nonmetallic alignment tools. The cores of many of the inductors/transformers in the typical CB rig are small and very fragile. Use a properly fitting tool and do not force it. A broken core usually jams in the form and is extremely difficult to remove without damaging the inductor or transformer. I broke the core in the synthesizer oscillator transformer in a Claricon CB and spent two hours on one conversion which should normally have taken less than fifteen minutes!

Finally, some cores are sealed in place at the factory using either a soft wax or a thin cement. For those cores sealed with wax, apply a small amount of heat to the wax to liquify it, using the tip of a soldering iron, while gently rocking the core back and forth with the alignment tool until the core loosens. For those cores sealed with cement, carefully chip away the cement using a small, sharp blade such as an X-Acto™ tool. These cements are more difficult to deal with than the wax, but are also not as commonly used.

Choosing a Band Plan

For those of you converting a sideband CB and looking for DX contacts, design your band plan to cover the lower 300 kHz of the phone band. I start with 28.510 MHz as channel 1, which keeps me comfortably away from the band edge. You will find plenty of action there!

For AMers, most of the activity I have observed is above 28.8 MHz. This is as it should be, because AM and SSB are not truly compatible. AM activity is still a little sparse, but should grow rapidly as the band conditions continue to improve and the number of CB conversions increases.

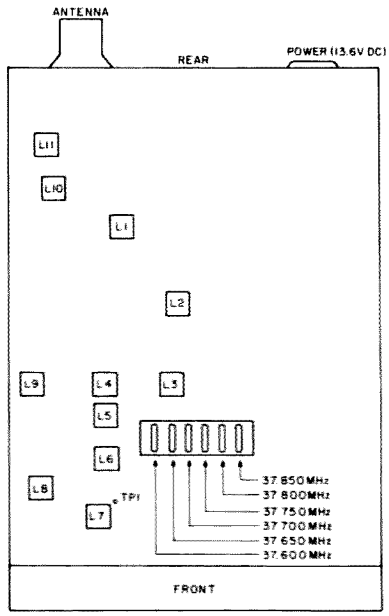

Fig. 2. Pace 123A.

Prior to my first AM conversions, several proposed band plans were in the literature. Unfortunately, none of these offered much in the way of either rationale or authoritativeness, so my first conversions started with 28.8 MHz as channel 1. I now favor the so-called "73 band plan" (see Wayne Green's editorial in the February, 1978, issue of *73 Magazine*). Although this plan offers no special magic over others I have seen, it has the support of the media (*73 Magazine*) and, for that reason, has a fighting chance of being generally adopted. The *73* band plan frequencies are exactly 2 MHz above their CB counterparts, with channel 1 being 28.965

Channel #	CB frequency	Original crystal	New crystal	10m frequency

Table 2. AM band plan.

MHz. At least two manufacturers (Standard and Bristol) have adopted the plan and presently market 40-channel 10 meter rigs.

A coordinated band plan offers many exciting possibilities for the channelized rigs. For example, moving mobile operation could be greatly simplified by designating certain channels as calling channels, similar to marine VHF operation. Once contact is made, the participants could move to another channel to carry on the QSO. Beacon stations would indicate when and to where the band is open.

Crystal Selection

Your choice of crystal frequency will depend on your band plan and the crystal lineup in your rig. Most rigs follow a 6-4-4 arrangement where the deck of six crystals serves as the master oscillator. For some sideband rigs, it is possible to retain both upper and lower sideband capability by changing only four crystals, while others require changing six crystals (it is assumed here that you are converting for a full 23-channel capability). Your *Photofacts* will indicate what crystal frequencies are used and how they are mixed to obtain the channel frequencies.

Once you have selected which crystals you wish to change and the frequencies of the new crystals, the problem of figuring the crystal formula arises (load capacitance, parallel/series resonant, fundamental or overtone mode, etc.). Here is where it is wise to choose an established crystal company for your supplier. Most of these keep an up-to-date file on amateur, CB, and commercial equipment using crystals, and can really help you here. I have dealt with Sentry (800-654-8850) in Chickasha, Oklahoma, and have found them to be both helpful and friendly. Their crystals work and the prices are reasonable.

By-the-Numbers Conversion

The following describes a step-by-step approach for converting some example CB rigs, using the bare bones of test equipment. It is the technique I now use and it works!

SBE "Sidebander III" — This is the first rig I converted and the one that is going to win me WAS. The rig uses two synthesizer oscillators, one switching six crystals in the 11.7-MHz range and one switching four crystals in the 7.4-MHz range. Since this rig retains both upper and lower sideband capability whichever synthesizer frequency is changed, the obvious choice is the 7.4-MHz oscillator. Since I wished channel 1 on the converted rig to be 28.510 MHz, and CB channel 1 is 26.965 MHz, it was necessary to raise each crystal frequency in the 7.4-MHz oscillator by exactly 28.510 minus 26.965 MHz or 1.545 MHz. The crystals were ordered, and, on receipt, the conversion was performed using the following step-by-step procedure:

Step 1: Remove cover from the rig and connect to 12-volt power supply.

Step 2: Plug in microphone (necessary for this rig to receive), and attach piece of wire to center terminal of antenna connector.

Step 3: Preset all controls as follows:
channel switch to channel 1;
noise limiter switch off;
squelch control fully counterclockwise (squelch open);
CB/PA switch to CB;
rf gain control fully clockwise (max gain);
on/off volume control on and fully clockwise;
USB/LSB switch in USB;
clarifier control — any position.

Step 4: Apply power (you will hear noise and possibly CB signals coming over speaker).

Step 5: Remove 7.4665-MHz crystal and replace with 9.0115-MHz crystal. See Fig. 1. Noise over speaker will greatly diminish with this operation.

Step 6: Using appropriate alignment tools, tune T5 and T6 (synthesizer mixer), T7 (USB buffer), and T1 and T2 (receiver rf amp) for maximum noise level over speaker (this completes all necessary alignment to receive 10 meters on upper sideband).

Step 7: Switch USB/LSB switch to LSB and tune T8 and T9 (LSB mixer) and T10 (LSB buffer) for maximum noise level over speaker (this completes the receiver alignment).

Step 8: Remove piece of wire from antenna connector, connect power meter to antenna connector, and dummy load to power meter (don't use antenna as load as this creates unnecessary QRM on 10 meter band while you are tuning up the transmitter).

Step 9: Depress microphone button, and, while whistling into the microphone at as steady a level as possible, tune T14, T15, T16, L4, L3, L2, and L1 for maximum indicated power output (this rig operates sideband only, and it must

be modulated to obtain any power output).

Step 10: Replace the remaining 37-MHz crystals with their 10 meter counterparts, set the channel switch to channel 13, and repeat steps 2 through 9 (this "centers" the alignment over the band span of the rig).

Step 11: Button up the rig; it is ready to go on the air!

Pace 123A—This is an AM rig I converted to operate with 28.8 MHz as channel 1, resulting in the band plan listed in Table 2. The rig uses a master synthesizer oscillator that switches six crystals in the 37.8-MHz range. I purchased replacement crystals having frequencies 28.8 minus 26.965 MHz, or 1.835 MHz higher than their counterparts. The steps for this conversion were as follows:

Step 1: Remove cover from the rig and connect to 12-volt power supply.

Step 2: Attach piece of wire to center terminal of antenna connector (the rig will receive without the microphone being plugged in).

Step 3: Preset all controls as follows:
channel switch to channel 1;
LCL/DIST switch to DIST;
squelch control fully counterclockwise (squelch open);
CB/PA switch to CB;
on/off volume control on and fully clockwise.

Step 4: Apply power (you will hear noise and possibly CB signals coming over speaker).

Step 5: Remove 37.600-MHz crystal and replace with 39.435-MHz crystal. See Fig. 2. Noise over speaker will greatly diminish with this operation.

Step 6: Using appropriate alignment tools, tune L3 (synthesizer oscillator) and L1 and L2 (receiver rf amp) for maximum noise level over speaker (this completes all necessary alignment to receive 10 meters).

Step 7: Remove piece of wire from antenna connector, connect power meter to antenna connector, dummy load to power meter, and plug in microphone.

Step 8: Depress microphone button and carefully tune L4, L5, and L6 (transmit mixer), and L7, L8, L9, L10, and L11 for maximum indicated power output. (The tuning of L4 through L6 is a bit tricky since you will have little or no output power to go by until these three are in tune. Turn the cores in a little at a time until an indication is obtained. If you have a VTVM or scope, observing the transmit buffer emitter voltage at TP5 makes things easier. The emitter voltage rises as you approach proper tuning.)

Step 9: Replace the remaining 7-MHz crystals with their 10 meter counterparts, set the channel switch to channel 13, and repeat steps 2 through 8 (again, to "center" the rig alignment).

Step 10: Button up the rig; it is ready to go on the air!

The Pace 113 uses a board identical to the Pace 123A, and the conversion procedure is therefore identical. I have used this approach with each rig I have converted, and, if done carefully, the final result is as good as if done with a laboratory full of instruments.

In closing, 10 meter band openings are becoming more and more frequent and lasting longer and longer each time. The converted CB rig gives you an easy in to QRP operation and a dandy mobile rig that is easy to operate. ■

MAKING SPECIAL CALL SIGNS AVAILABLE TO STATIONS LICENSEE TO AMATEUR EXTRA CLASS OPERATORS

AGENCY: Federal Communications Commission.

ACTION: Second Report and Order.

SUMMARY: The Commission is terminating its proposal to allow Amateur Extra Class licensees to request certain types of specific call signs.

EFFECTIVE DATE: Nonapplicable.

ADDRESSES: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION:

Contact Mr. Joseph Johnson, FCC 1919 "M" Street NW., Washington, D.C. 20554, 202-632-7175.

SUPPLEMENTARY INFORMATION: See attached document.

In the matter of amendment of part 97 to make special call signs available to stations licensed to Amateur Extra Class operators. (Docket 20092; See 41 FR 17734).

Adopted: October 19, 1976.
Released: October 26, 1978.
By the Commission:

1. A Notice of Proposed Rule Making in the above captioned matter was released on July 2, 1974. In that Notice, the Commission proposed to amend Part 97 of the rules to permit Amateur Extra Class licensees to request any available specific unassigned call signs for their primary and/or secondary stations. It was also proposed to discontinue the availability of "in memoriam" call signs, i.e., call signs requested by Amateur club stations for the purpose of honoring a deceased member.

2. On April 22, 1976 the Commission adopted a First Report and Order in this proceeding which adopted in part the proposals made in the Notice. Specifically, Amateur Extra Class licensees were permitted to request specific "two-letter" all signs, (call signs consisting of a single or double letter prefix, a digit, and a two letter suffix); action was deferred on permitting licensees to request specific "three-letter" call signs, (call signs consisting of a single or double letter prefix, a degit, and a three letter suffix). On March 11, 1977, the Commission released a Notice of Proposed Rule Making in Docket 21135 which, among other things, proposed to delete from the rules the provisions adopted under Docket 20092 which permitted Amateur Extra Class licensees to obtain specific call signs of their choice. On February 23, 1978, a First Report and Order in Docket 21135 was released which adopted this proposal. This action was taken because of the additional workload imposed by the call sign program. In amending its rules, the Commission provided that, henceforth, all call signs would be assigned systematically, with the details of the system to be announced.

3. In light of our experience with the call sign provisions adopted under Docket 20092, we see not further usefulness in continuing that proceeding. Therefore, It is ordered that Docket 20092 is terminated effective immediately.

FEDERAL COMMUNICATIONS COMMISSION,
WILLIAM J. TRICARCIO,
Secretary.

GRS HAS SYMPOSIUM, TOO

For some of the DOC headquarters people attending the amateur symposium, it was the second weekend in a row devoted to radio users. At a National GRS Symposium held in Ottawa on September 21, the DOC unveiled a plan for 100 new GRS ("CB") channels in the 900 MHz area. In a speech for the Minister of Communications, (parliamentary assistant) Crawford Douglas of the DOC forecast that the GRS would evolve into a sophisticated technology which could be integrated with telephone and computer systems. Good news for amateurs was the fact that Dr. John deMercado, head of the Regulatory Service, stated, in answer to the GRS complaint that they were often blamed for TVI in poorly designed sets, that the first well-shielded sets would be on the market next year. This move would be of little significance in solving the problem for the GRS and amateurs for 4 or 5 years.

Better news still was the fact that in Mr. Douglas's speech, when reference was made to the fact that the DOC was considering 900 MHz for the GRS, there was no reference to the use of the 220 MHz band for this purpose. CARF sources in the U.S. forecast that an October 12th meeting of the FCC would also kill the idea of 220 MHz for the CB.

OSCAR Orbits

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. Due to incorrect tracking information obtained during the early days of OSCAR 8, the equator crossing times contained in most published charts are in error. To correct this error, multiply the orbit number by 0.00205 minutes and add the result to the equator crossing time as printed in the chart. For example, the published time for orbit number 3352, the first equatorial crossing on November 1, 1978, is 0018:50 UTC. Thus, for orbit number 3352, the corrected equatorial crossing time would be:

$$\text{Corrected time} = 0018{:}50 + (3352 \times 0.00205 \text{ minutes})$$
$$= 0018{:}50 + (6.8716 \text{ minutes})$$
$$= 0025{:}42.3$$

The longitude figures contained in the OSCAR 8 chart are virtually unaffected by this tracking error. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon at 435.090 MHz.

Electronics Education by Mail Order

—successful student reports

A trade school extension course may be your ticket to a ticket.

R.S. Isenson N6UE
4168 Glenview Drive
Santa Maria CA 93454

Have you ever wondered, while reading the advertising for electronics courses, what it would be like to take one? In common, the schools, institutes, or whatever they call themselves, emphasize the "goodies" that come with the course: 25-inch color TV sets, quadraphonic stereos, digital computers, various types of mouth-watering test equipment, and even transceivers. It's almost a case of, "If you can name it, someone offers it!" Sometimes the promises sound almost too good to be true, yet you sort of feel that most, if not all, of the heavily advertised correspondence schools must have fairly decent integrity. They must, in one way or another, meet their advertising claims or the post office would grab at them like an alligator on a short-squelch-tailed repeater going after a windbag.

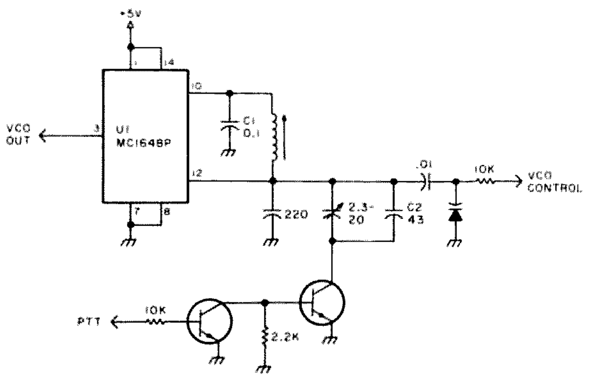

Fig. 1. Voltage-controlled oscillator.

From the advertising, it's obvious that some of the schools offer Heathkits as the hardware inducements. Others claim to offer kits of their own design. If it's the former, the Heath catalog spells out the specifications for the would-be student. If it isn't, it could be pretty tough to assess the hardware unless someone else who's taken the course broadcasts his experience. The latter is what this article is all about: my experiences with and impressions of one of the correspondence courses, and my personal, nonprofessional assessment of the "main goody," the CONAR 452 2 meter transceiver.

Late in 1976, NRI (The National Radio Institute, Washington, DC) announced a new communications/electronics course that held out, for me, a double appeal. First, their advertising promised that, if one pursued the course to its conclusion, he would be able to pass the FCC Commercial First Class Radio/Telephone examination, or his money would be refunded. Second, the pièce de résistance of the home study course was a digital, phase-locked-loop, synthesized 2 meter transceiver.

Having a requirement, at that time, for a Commercial First Class ticket, and knowing full well that I needed some motivation—like a significant financial commitment—to keep my nose in the books, the NRI course made a lot of sense. The fact that my 2 meter FM capability consisted of a clobbered together,

many-times-recycled VHF Engineering transmitter strip, and a salvaged Pace HF/VHF scanner, didn't make the synthesized rig any less appealing. So I signed the contract form, letting myself in for a reasonably solid educational experience as well as a lot of aggravation and a bit of exasperation. Ye who seek the first and would avoid the latter, read on!

NRI advertises that the student sets his own pace. The hard rock truth is that this isn't necessarily so, particularly if, as in my case, the student plans to get through the course in less than six months. Perhaps a 12 to 18 month schedule is more in keeping with the Institute's gearing. That impedance mismatch accounted for a considerable part of my unhappiness, but far from all of it. The real heartburn was caused by the very much delayed delivery of significant parts of the 2 meter transceiver.

NRI, and probably every one of the other correspondence schools, sends kit hardware to the students in subassembly portions. The student assembles the hardware in that packet, conducts some prescribed experiments on or with it, mails to the school the answers to some questions pertaining to the experiments, and waits for the school to make the next move. Receipt by the school of the set of answers supposedly triggers the next shipment. Three "training kits" contain the hardware for the CONAR 2 meter transceiver. Five months transpired between the time that I mailed the answers to questions on the first kit and I received the third kit; five months, a number of protesting letters, and a couple of cross-country telephone calls spells "exasperation" to me.

I learned, after receiving the third kit, that the fault wasn't all NRI's. The Institute had been caught up in the April 15, 1977, "Purity of Emission" FCC regulation change (Part 97.73). NRI had to rework the final and output filter to meet the 60 dB spurious emission limit in order to get FCC type approval. Had the Institute only said something about their problems when I first started complaining, some aggravation could have been avoided. If there's a lesson to be learned from all of this, I guess it's threefold: Don't try to get through an extension course in a hurry, don't be in a hurry to sign up for a newly offered course, and don't expect a correspondence school to be sensitive to student personnel problems.

Photo A. CONAR 452 2 meter synthesized transceiver. CONAR 380 power supply.

The academic program was found to be reasonably comprehensive, touching on almost every significant facet of communications/electronics. The proclaimed objective of the course is preparation for the FCC Commercial First Class radiotelephone license. Therefore, it wasn't surprising to see primary attention focused on entertainment and commercial communications equipment rather than amateur gear. Similarly, concern with FCC regulations is for parts other than Part 97 (Amateur Radio Services). The technical level is trade school rather than university. That is, high school algebra is all one needs for the mathematical background.

The "Complete Communications/Electronics" course consists of 57 lessons, each including a short multiple-choice test, a set of 14 supplemental study guides, each with a pamphlet containing a number of FCC-type questions designed to prepare the student for the Commercial Class license, and ten hardware kits. The kits include a TVOM, a modern version of a breadboard with built-in power supplies and provisions for quickly setting up prototype circuits of discrete components or ICs, a 6- to 7-MHz digital frequency counter, a crude but practical antenna test facility, a regulated power supply, and the 2 meter transceiver.

The antenna range can be a useful addition to any ham shack.

After completing the NRI prescribed antenna modeling and tests, I used mine to try out scale models of various low-band antenna configurations, the full-size versions of which could be fitted into the backyard of the home QTH. That exercise resulted in the gaining of some interesting antenna insight, and the empirical design of a much improved (for me) 75 and 40 meter antenna system. But that's another story!

In short, except for the difficulty in attaining my desired time schedule, the course was interesting and fun. Anyone completing it should have no difficulty with the technical portion of any FCC commercial or amateur licensing exami-

nation. The ham need only brush up on the legal aspects of Part 97 and get his code speed up to go right through to an Extra Class ticket. So much for my impression of the academics. Now on to the CONAR 452 2 meter transceiver.

Photo A shows the rig along with the ac power supply furnished as part of the course. The transceiver isn't small. It measures 4" high × 8¼" wide × 11½" deep, as compared to, for example, the 2¾" × 8¼" × 9-7/8" of the Heathkit HW-2036A, and the latter is no pygmy. It weighs about one ounce less than the HW-2036A's 6.25 lbs. The front panel is fairly clean, with a seven-segment LED display for receiver frequency. Additional LED displays indicate transmitter offset status, phase-locked-loop status, and the 5-kHz increment. As a real boon for under-dash mounting, it has a front-panel-mounted speaker. Much of the size of the NRI rig is attributable to a design concept resulting in outstanding accessibility. This is one of the easiest pieces of electronic gear to work on that I've seen since germanium replaced the vacuum.

Photo B shows the transceiver with its top cover removed and with the receiver board extended. Each of the other four boards can be extended, one at a time, for test or alignment purposes. Front and rear panels (Photo C) swivel out on the assembly screws to afford access to components mounted on those panels.

The transmitter has a switch-selected high/low power option. As measured with a Thruline wattmeter to a matched dummy load, low rf power out was between 2.5 and 3 Watts across a selected 2-MHz portion of the 2 meter band. In the high-power position, the rf output varied between 19.5 and 20 Watts over the same 146-to 148 MHz portion of the band. On-the-air reports were good. The rig has a clean, natural sound.

For the receiver, a 0.5-microvolt signal was crudely measured to be the squelch threshold. A 4-microvolt signal into the antenna terminal resulted in absolutely full quieting. Numbers aside, the CONAR 452 offers an adequate receiver with acceptable sensitivity and selectivity. It has double conversion i-fs, 10.7-MHz and 455-kHz, with crystal filtering or control on each. It has, however, a couple of design weaknesses, the first of which took an embarrassing number of hours to identify and reduce.

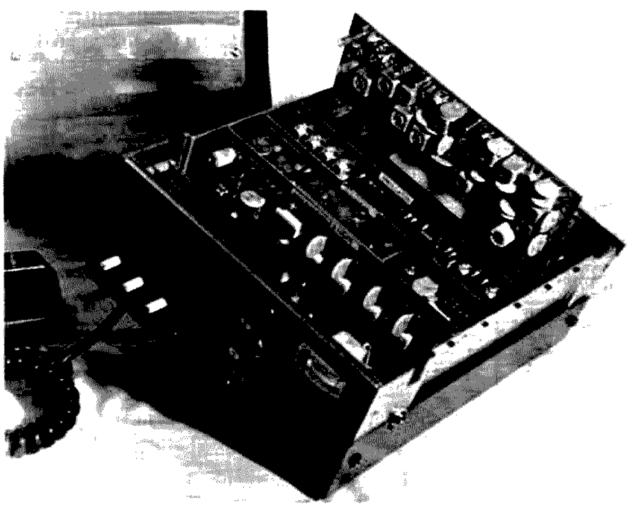

Photo B. CONAR 452 transceiver with top cover removed and receiver board extended.

Remember my comment about the clever layout that permitted the front and rear panels to be swung out for component accessibility? The design is great for maintenance, but it doesn't afford a very good electrical path between the end panels and the main chassis. NRI neglected the latter point. The volume control and squelch control potentiometers are both "grounded" to the front panel. The result, at least in my rig, was a ground loop that, in turn, furnished enough feedback to drive the LM380 audio amplifier into oscillation at the volume setting needed to override my "VW-type QRN." After much fumbling and groping, the problem was identified and reduced by adding a grounding strap from the front panel to the main chassis and running a separate wire from the bottom side of the two potentiometers to a clip fastener that was added to the audio board. The clip fastener was used to retain the flexibility of board removal.

The other audio problem results from the configuration of the top and bottom covers. These rather large, unsupported, flat metal surfaces find their resonant frequencies low in the audio band. At high volume settings, they tend to vibrate noisily! Some strips of electrician's rubber tape applied so as to provide pressure contacts between the top cover and the internal baffles of the housing (Photo B) help some, but don't eliminate the problem.

Assembly of the transceiver was straightforward. Most of the components mount on one or another of the five PC boards. The instruction manuals are very similar to those of Heath. A few errors were spotted, and there were a few examples of things being done the hard way. The kits were short a few components, though nothing significant—a couple common resistors and some discaps. I had all of the necessary replacements in the junk box. Comments on the discrepancies, textual and component, were sent to NRI, and the missing parts were received by return mail. The other comments may well have been reduced to errata notes. The parts shortages and assembly instruction errors are just part of the price one pays for being in a hurry to try a newly announced kit, I guess!

For some reason, NRI chose to use ½-Watt and larger resistors. This undoubtedly adds to the size and weight of the transceiver without offering any obvious compensation unless it's lowered parts cost.

A multiple component problem in the voltage controlled oscillator of the PLL synthesizer almost drove me up that proverbial wall! The digital, phase-locked-loop synthesizer is the well known, circa 1970, Motorola circuit. Finding it in a transceiver that supposedly was a 1976 design was a bit disappointing. In light of all the CMOS one- and two-chip synthesizers that have reached the market in the last few years, it's difficult to understand why NRI opted for the power-hungry, high-part-count TTL approach, unless it was the lower cost of TTL and its relative immunity to static discharge. The first indication of trouble was the observation that the MC1648 voltage-controlled oscillator had two modes of operation. At random, it would oscillate at nominally 24 MHz, where it should have, or at about 43 kHz. If power was

applied to the transceiver and the vco went into the low-frequency mode, it would remain there until something upset it, such as flicking power off and back on. Once I was aware of the phenomenon, it was easy enough to tell when the vco was in the wrong mode—the loop-unlock warning lamp would remain on! The precise frequency of oscillation in either mode could be varied by adjusting the tank coil (Fig. 1). This, of course, pointed to the chip as the part at fault. Additionally, in the desired 24-MHz mode, the oscillator was very unstable, drifting slowly up and down with peak frequency excursions sometimes exceeding 300 kHz. For all practical purposes, the set was inoperable.

Replacing the 14-pin DIP MC1648, a nasty job because it's soldered to the PC board, eliminated the low-frequency oscillation mode, but didn't affect the drift problem. The latter was finally reduced to a tolerable level by replacing, one by one, every frequency-determining component in the vco circuit. Replacing the 43-pF silver mica used to offset the vco in the receive mode (Fig. 1.) helped considerably, but not enough. The 43 pF is an odd value. I didn't have one, so I used the more common 47 pF. It worked fine.

Final stabilization of the vco required replacing a 0.1μF discap with a polystyrene capacitor of the same value. In the circuit diagram, it looks like a simple bypass capacitor, and why it should make a difference is anyone's guess. In fact, replacing it was a desperation move; everything else had already been tried!

There's much sentiment against using ICs for vcos. Describing the new 11C85 PLL synthesizer in the November-December, 1977, issue of Fairchild's *Journal of Semiconductor Progress*, Eric Breeze said, "After considering the stringent vco requirements . . . it was concluded that discrete components offer more flexibility and better performance than anything that could be built on a chip." After hours and hours of fighting that vco stability problem, I can only say, "Hear! Hear!" As long as the MC1648 was involved, there was no way that I could visualize the full role played by that discap or the possibilities of its interactions. I suspect that this circuit will cause NRI considerable heartburn!

The TTL phase-locked-loop synthesizer and the LED readouts are significant contributors to the power appetite of this transceiver. In the receive mode, it takes about 1.5 Amps at 13 V. In the transmit mode, I measured about 2.5 Amps drawn in the low-power mode and about 5 Amps in the high-power mode.

In my judgment, another questionable choice of components was the T-R relay (Photo C). The relay is open framed and is mounted at the rear of the unit between the louvers in the top and bottom covers. Every time the PTT switch is closed, a field is created around that relay. Particularly in the dusty vehicular environment for which this type of rig is intended, that field will attract an oil and dirt film to the contact points. The relay should be replaced with an enclosed type. Hopefully, NRI will see fit to offer a more suitable, compatible replacement. I'll be pleased to pay a reasonable price for one.

On the positive side, in addition to the excellent mechanical layout, NRI has built in several nice features. Recall that 6- to 7-MHz digital-frequency counter? Bet you wondered what good that could be for aligning a 2 meter rig, didn't you? Well, by cleverly making use of the decade-dividing circuit that's part of the 10-MHz reference-frequency oscillator, NRI divides the receiver and transmitter simplex and offset frequencies from their 23- to 24-MHz range down to a figure that's 1/10th of that. The latter is easily handled by the little counter.

Photo C. Top cover removed to show swing-out panels and T-R relay.

Rf and i-f alignment are accomplished by using an already-present, harmonic-rich, 1-MHz TTL square wave as a signal source. It's a clever concept and permits a surprisingly good alignment. I double checked with a fairly elegant sweep generator and a wideband scope. Improvement in performance, if any, resulting from the more elaborate alignment technique, wasn't obvious.

The synthesizer is supposed to cover 400 channels, that is, any 2 MHz of the 4-MHz band in 5-kHz increments. Actually, it retains lock through almost 3 MHz of the 4. This may change as components age.

The power supply shown in Photo A has a variable voltage output—5 volts to about 15 volts. NRI rates it a 4-Amp steady load to 6 Amps with a 50% duty cycle. The heart of the power supply is the relatively new Fairchild 78GKC 4-lead TO3. Fairchild rates the device at 5 Amps. The supply is very well regulated and should be a welcome addition to any bench, as well as serve as an ac supply for the transceiver when it's in the shack.

I understand that the transceiver and the power supply are available from NRI in kit form, independent of the entire communications/electronics course. It's quite clear that the design engineers on the CONAR 452 transceiver were very cost-conscious. If NRI passes these savings along to the kit buyer, this 2 meter rig could be a very good buy.

Some weaknesses have been identified, but the fixes were described. Having debugged the transceiver, it's going to be a very adequate mobile rig, and I'll stack up its performance against anyone else's rig. That's about all I can say for it.

Finally, I didn't get a chance to test NRI's money-back guarantee. I got my First Class Commercial radiotelephone ticket, with radar endorsement, on the first try! ■

LAPORTE IN
FEB 25

The LaPorte Amateur Radio Club will hold its winter hamfest on Sunday, February 25, 1979, at the LaPorte Civic Auditorium, LaPorte, Indiana. There is a $1.00 table charge. Donation is $2.00 at the gate. Talk-in on .01/.61 and .52. For more information, contact LARC, Box 30, LaPorte IN 46350.

AKRON OH
FEB 25

The Cuyahoga Falls Amateur Radio Club will hold its annual electronic equipment auction and flea market on Sunday, February 25, 1979, at North High School, Akron, Ohio, from 9:00 am to 4:00 pm. Tickets are $2.00. You may bring you own tables, and there will be some available for $2.00 each. There will be refreshments, prizes, and a grand prize of a Triton IV. There is easy access to the high school on the Tallmadge Avenue off-ramp and the North Expressway (Rt. 8). Talk-in on 146.52 and 146.04/.64. For details, write CFARC, PO Box 6, Cuyahoga Falls OH 44222, or phone Bill Sovinsky K8JSL at (216)-923-3830.

DAVENPORT IA
FEB 25

The Davenport Radio Amateur Club will hold its hamfest on February 25, 1979, at the Masonic Temple in Davenport, Iowa. Admission is $2.00 in advance, $2.50 at the door. Refreshments and tables will be available. Talk-in on .28/.88 and .52. For further information, send an SASE to John S. Birmingham WB0QCC, 2022 Brown St., Davenport IA 52804.

LIVONIA MI
FEB 25

The Livonia Amateur Radio Club would like to announce that the 9th annual LARC Swap 'n Shop will be held on Sunday, February 25, 1979, from 8:00 am to 4:00 pm, at the new location of Churchill High School in Livonia MI. Tables, door prizes, refreshments, and free parking will be available. Talk-in on 146.52 simplex. Reserved table space of 12-foot minimum is available. For further information, send an SASE to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48151.

VIENNA VA
FEB 25

The Vienna Wireless Society will hold its annual Winterfest on Sunday, February 25, 1979, at the Vienna Community Center, Vienna, Virginia. There will be tables, sales, prizes, food, and frostbite tailgating. Doors open at 6:30 am for vendors and 8:00 am for the general public. Admission is $3.00, including one prize ticket; $2.00 for an extra prize ticket and $1.00 for frostbite tailgaiting. Preteens with parents are free. Tables range from $2.00 to $5.00, depending on the quantity. Reservations close on February 15, 1979. For reservations, contact Carroll N. Guin, 7533 Oak Glen Court, Falls Church VA 22042. For information, contact the Vienna Wireless Society, PO Box 418, Vienna VA 22180.

VERO BEACH FL
MAR 17-18

The Treasure Coast Hamfest will be held on March 17-18, 1979, at the Vero Beach Community Center, Vero Beach, Florida. Activities will include prizes, drawings, and a QCWA luncheon. Admission is $3.00 per family. Talk-in on 146.13/.73, 146.52/.52, and 222.34/223.94. For information, write PO Box 3088, Vero Beach FL 32960.

WAUKEGAN IL
MAR 25

The Libertyville and Mundelein Amateur Radio Society will hold its second annual Lamarsfest on Sunday, March 25, 1979, at the J. M. Club, 708 Greenwood Ave., Waukegan, Illinois. Doors will open at 7:00 am. There will be plenty of free parking, door prizes, and a large indoor flea market for radio and electronic items. Tables will be available at $4.00 each. Advance tickets are $1.50; $2.00 at the gate, with children under 10 free. Hot lunch will be available and there will be plenty of commercial exhibits and demonstrations. Talk-in on 146.94. For further information, write LAMARS (include SASE, please) at 1226 Deer Trail Lane, Libertyville IL 60048, or call (312)-367-1599.

MUSKEGON MI
MAR 30-31

The Muskegon Area Amateur Radio Council is sponsoring the ARRL Great Lakes Division Convention and Hamfest at the Muskegon Community College in Muskegon, Michigan, on March 30-31, 1979. This event will feature manufacturers' exhibits, technical forums, and a large swap shop. Ample parking and dining facilities are available. Friday evening at the Muskegon Ramada Inn, there will be a "Ham Hospitality" with libation courtesy of the MAARC and a Wouf Hong initiation. For additional information, contact MAARC, PO Box 691, Muskegon MI 49443, or H. Riekels WA8GVK, (616)-722-1378/9.

UPPER HUTT NZ
JUNE 1-4

The 1979 Annual Conference of the New Zealand Association of Radio Transmitters will be held on June 1-4, 1979, at Upper Hutt, New Zealand. Visitors are welcome to attend this conference. For registration forms, contact the Secretary, 1979 Conference Committee, PO Box 40-212, Upper Hutt NZ.

LOUISVILLE KY
JUN 29-JUL 1

The Louisville Area Computer Club will hold its 4th annual Computerfest™ 1979 from June 29 through July 1, 1979, at the Bluegrass Convention Center, Louisville, Kentucky. Activities include a flea market, seminars, and exposition, as well as activities for the entire family. Seminar and exposition admission is $4.00. Pre-registered Ramada Inn guests ($29.00, single; $34.00, double) receive free admission. For advance mail information, write Computerfest '79, Louisville Area Computer Club, PO Box 70355, Louisville KY 40270, or phone Tom Eubank, Chairman, at (502)-895-1230.

GEORGETOWN IL
SEP 1-2

The 1979 Danville, Illinois, Area Hamfest will be held on September 1-2, 1979, at the Georgetown, Illinois, fairgrounds, located ten miles south of Danville on Illinois Rt. 1. Gates open at noon on Saturday for vendors to start setting up their displays. Gates open to the general public at 6:00 am Sunday. Facilities will consist of a large enclosed building 50 × 150 feet with electrical hookups available at no charge. Please bring your own tables and chairs and power cords. Outside space is also available at $2.00 per person gate charge. Overnight camping on the fairgrounds is available at $5.00 per vehicle. For information, contact Bob Wilson K9RBW, c/o Illiana Repeater Systems, Inc., PO Box "G", Catlin IL 61817.

Ham Help

I live close to an AM radio station and will be moving even closer to another one. I use an old army surplus receiver for shortwave and cannot use it at all when that station is on the air. Could anyone give me information on an article, or a copy of one, that would help me build a filter to filter out the broadcast station? Thank you very much.

Terry D. Wright WB8UPO
525 South Downing St.
Piqua OH 45356

I need a diagram or information on a "CHIBA" model CPF12 6-channel 2m hand-held transceiver with 16/76, 34/94, and 94 simplex built-in crystals.

Jung Y. Lem KB6BO
5222 Coringa Dr.
Los Angeles CA 90042

Does anyone have any information or a schematic on a Poly-Comm "B" 29-MHz transceiver? I will buy manual for above or pay for a copy. Thank you.

Peter J. St. Arnaud
PO Box 695
Lowell MA 01853

I need information about terminal antennas for satellite TV. Any info about suppliers for these kits would be greatly appreciated. Thanks.

Steve Hutchens
Rt. 1 Box 186C
Boonville NC 27011

I would like to add electronic switching to my TS-520S so that I might have full break-in on CW. If possible, I would like to leave the VOX circuit intact for SSB operation, but I would sacrifice that for the full break-in feature. I wonder if anyone has made this modification?

Time-Domain Reflectometry

— to check out your transmission lines

This added dimension simplifies the location of an antenna system fault.

When the band seems dead or, worse yet, when the band sounds alright but you can't make contacts as usual, how often have you wondered about the condition of your antenna system? This is certainly one of the more frustrating feelings an amateur experiences, especially if parts of the antenna system are not visible from the operating position.

There are many methods that can be used to check an antenna system. A simple ohmmeter reading, especially if the ohmmeter used has good resolution in the low Ohms range, is useful for antenna systems which form a closed dc loop for measurement purposes.

The measurement of swr at the transmitter end of the transmission line remains one of the most basic and useful of measurements in the average situation, although there are circumstances where swr readings can be misleading. For instance, depending on the attenuation of the transmission line involved at a given frequency, the swr read at the transmitter end of a transmission line will be lower than that existing at the transmission line/antenna interface. Theoretically, the swr at the transmitter end could look perfect while there was no antenna connected to the other end of the transmission line. No practical situation would normally approach this condition, however.

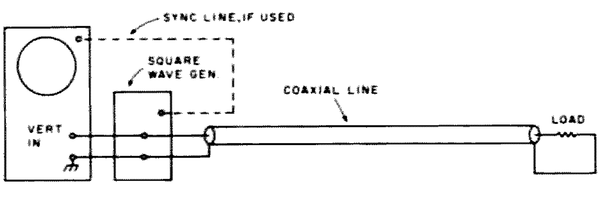

Fig. 1. Basic test setup for time-domain reflectometry. A fast-rise-time square-wave generator and a broadband oscilloscope are the basic test instruments needed.

Even if an swr reading indicates that something has changed in the antenna system, it does not give any information as to what might be at fault or where the fault might be located. "Time-domain reflectometry" is a rather impressive term for a transmission line measurement technique that can provide information on the nature and location of faults on a transmission line. In the commercial world, the equipment needed to make measurements using this technique can be sophisticated and expensive. The results can also be impressive — like being able to isolate a fault to a specific connector or almost down to the foot in an extensive cable TV distribution system.

The general improvement in quality of the test gear available even in the average ham shack, due to modern ICs, etc., makes the basic use of the technique interesting to explore for HF to VHF antenna system checks. Two basic items of test gear are necessary to implement the technique: a fast-rise-time square-wave generator and a broadband oscilloscope. (If a suitable square-wave generator is not available, a perfectly useful home-brew unit using only two ICs is described later.) The oscilloscope used should have a frequency response of 10 MHz or more, but some of the newer low-cost oscilloscopes which have a flat response to 5 MHz and a usable response up to several MHz more are also quite satisfactory for basic measurements (e.g., the Heath IO-4560 oscilloscope at $120). Older oscilloscopes with restricted frequency responses can also be used in many circumstances, but with varying results.

In simple terms, time-domain reflectometry works like a radar signal on a transmission line. The

square-wave generator sends out the necessary "pulse," and the scope is used to obtain a picture of the results. Problems on the transmission line or with the line termination will produce discontinuities on the oscilloscope display. The location of the problem is determined by knowing the speed at which the signal travels down the line and then noting where (time-wise on the horizontal sweep of the scope) a discontinuity occurs. With good equipment, one can calculate quite accurately the location of faults (opens, shorts, etc.) on the line, but this is not necessary in the average amateur installation. After having made a few good "signatures" of what the transmission line system looked like when it was known to be in good condition, and then comparing them to oscilloscope "signatures" when a problem occurs, one can be readily guided to the approximate location of a fault.

Fig. 1 shows the setup for measurement. The output of the square-wave generator is connected directly to the vertical input of the oscilloscope and to the coaxial line being tested. The connection should be as short as possible and preferably directly to the oscilloscope terminals. The square-wave generator to be described later can, in fact, be constructed compactly enough to fasten directly on the vertical input terminals of many oscilloscopes using binding posts or via a T-connector for oscilloscopes with a BNC- or UHF-type input connector.

It may seem a little difficult at first to understand why anything meaningful would be displayed on the oscilloscope with the square-wave generator output connected directly to the oscilloscope's input terminals. One may think the coaxial line just acts as a capacitor across the oscilloscope terminals. The key to the situation is to remember that the voltage step produced by the start of the square wave requires a finite time to travel down the coaxial line (the speed of light times the velocity factor of a specific cable). Therefore, the square-wave frequency used must be chosen taking into consideration the length of the coaxial line under test if a meaningful display is to be obtained. If the positive portion of the square wave lasts long enough timewise so that it is not completed before the length of time needed for the voltage step to travel down a given length of coaxial cable, any discontinuities in the line produce a reflection which travels back to the oscilloscope terminals. The reflected voltage adds or subtracts to the positive portion of the square wave which the oscilloscope is displaying and the pattern will change.

For instance, in Fig. 2(a), the coaxial line is terminated in a resistive load which matches the line. The square wave traveling down the line encounters no discontinuities, and so the oscilloscope display is essentially a square wave. In Fig. 2(b), the line is terminated in a load resistance which is less than the line impedance. The square wave, when it reaches the termination, is partly reflected back and, when it reaches the oscilloscope terminals, subtracts from the positive portion of the square wave the oscilloscope is trying to display. The display, therefore, is altered as shown. If the load resistance were higher than the line impedance, the reflected voltage would add to the displayed voltage.

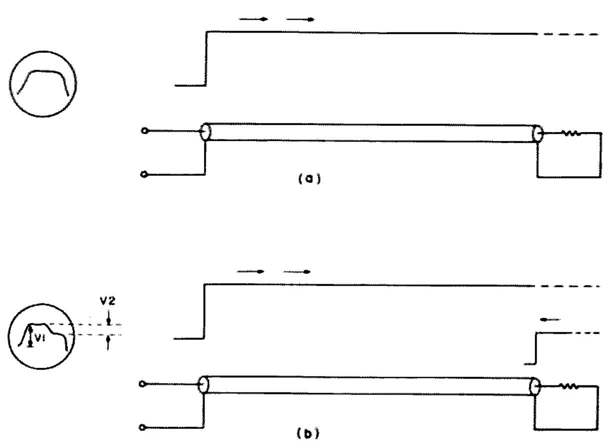

Fig. 2. The concept of a voltage step traveling down a line (a) and then part of that step being reflected back from an improperly matched load (b) is the basis for time-domain reflectometry.

The square-wave frequency used should be low enough to allow the reflection produced by a fault, even at the extreme end of the line, time enough to travel back to the oscilloscope terminals before the positive portion of the square wave is completed. On the other hand, the frequency shouldn't be lower than necessary or else resolution as to where a fault lies will be lost. One can calculate the optimum frequency for a given type of line, but it is rarely necessary to get so precise. Fig. 3 presents a rough guide as to the square-wave frequency one should use for given lengths of ordinary coaxial line.

If you have, or can borrow, two lengths of coaxial cable each at least 50 feet in length and the same impedance, I would suggest that the circuit of Fig. 1 be tried out. Use a resistor equal to the line impedance, and resistors lower and greater in value than the line impedance to terminate the line. Also, short and/or terminate the junction of the two sections of cable with various resistors.

Most amateurs do not believe the technique works until they try it out in this fashion. The idea of a reflection actually travel-

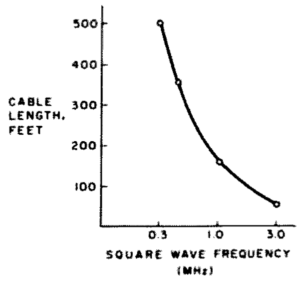

Fig. 3. This graph shows approximately what generator frequency to use when testing different lengths of line. Using a variable frequency generator, the generator frequency is actually adjusted for the best oscilloscope display.

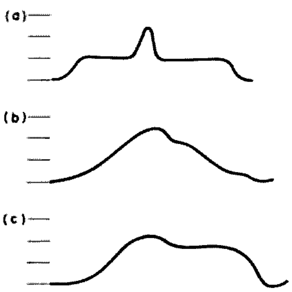

Fig. 4. These are some actual oscilloscope patterns obtained. (a) shows a line with a short circuit in the center of its run. (b) and (c) are discussed in the text and show the effect of an antenna fault.

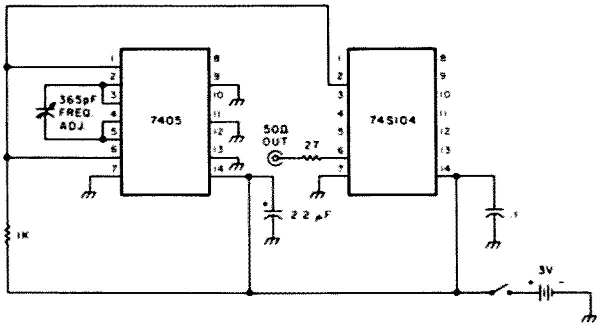

Fig. 6. Extremely simple square-wave generator has adjustable frequency output of 300 kHz to 3 MHz with a rise time of only a few nanoseconds. It is powered by two flashlight cells (C- or D-size) in series.

ing back up a line from a mismatched load is sometimes a difficult idea to grasp. The oscilloscope patterns one obtains depend upon the quality of the equipment used, but they should duplicate that of Fig. 2(a) for a properly-terminated line, that of Fig. 2(b) for a line terminated in a low-value load resistor, and that of Fig. 4(a) for a line terminated in its correct load resistance but with a short in the middle of the line. Obtaining an exact display is not so important as noting how sensitive the display is to changes in load terminations and to faults which take place at different places along the line.

If one can obtain a very sharp display, it will be noted that the display of Fig. 2(b) can be related to the load swr. V_2 is the reflected voltage amplitude and V_1 is the incident voltage amplitude. The swr is $(V_1 + V_2)/(V_1 - V_2)$. For instance, if V_1 is 2 volts and V_2 is 0.5 volts, the swr is 1.67. This type of display can be very useful for classroom situations where swr must be explained, and especially when you must make the point that terminating a transmission line in its characteristic impedance is important in most cases.

Applying the measurement technique to an actual antenna system produces more complex oscilloscope displays because of the reactances involved. But the technique can still be very useful if one is consistent with a test setup — that is, using the same length of test leads, square-wave frequency, amplitude, etc. One should obtain an oscilloscope "signature" of the antenna system as measured from the transmitter end when the antenna system is known to be in good order. If possible, a few faults should be simulated to see how the oscilloscope display changes. The actual faults, if they take place, will be relatively easy to identify. For instance, Fig. 4(a) shows the display obtained on a given antenna system when the transmission line was terminated in a dummy load but shorted in the center of its run. Fig. 4(b) shows the display of an antenna system using a multiband trap antenna but with two lengths of coaxial cable of the same impedance but different type (RG-58 and RG-8) hooked together to form a single transmission line. Fig. 4(c) shows the change in the display when one of the antenna loading coils was partially shorted to duplicate a fault in the antenna. The change in swr at the terminal end, as measured with a conventional swr meter, was barely noticeable in this case, although the oscilloscope display change was easily noticed. Again, it deserves some emphasis to note that the oscilloscope display obtained with any given antenna system will be unique depending on the system and the test equipment being used.

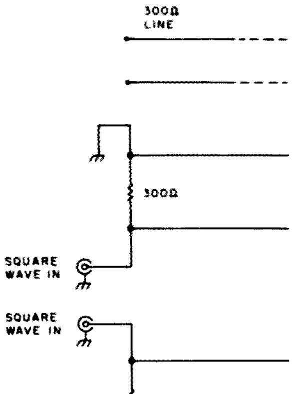

Fig. 5. Systems using a balanced line can be checked also. The line is terminated by a resistor as shown and then the square-wave signal applied alternatively to either side of the line. The balance of the line is also checked by this method.

For those amateurs who use a balanced transmission line/antenna system, the measurement technique described can still be used. For instance, if one uses a 300-Ohm transmission line system, the line is terminated at the transmitter end as shown in Fig. 5, and the square wave signal is alternatively applied to both sides of the line. Faults in the system will be displayed in the same manner as for a coaxial system when testing either side of the balanced line. The oscilloscope pattern obtained when testing either side of the balanced line should be the same if no faults are present and acts as a check on the true symmetry of the balanced system.

The purpose of the measurement technique described is to discover faults in an antenna system, either along the transmission line or in the transmission line termination — the antenna. One, therefore, has to start with a matched condition at the square-wave generator/coaxial line terminus, or else a confusing oscilloscope display will be obtained. Any sort of mismatch will cause a reflection in the system under test, and the reflection will bounce back and forth between mismatched or fault points in the system. Thus, if the square-wave generator/coaxial line end is not properly matched, a reflected voltage from a mismatched load will be reflected up the transmission line again once it meets the square-wave generator/coaxial line mismatch. Fortunately, this situation is easily prevented. The output of the square-wave generator being used, assuming its output impedance is at least several hundred Ohms, should be terminated in a resistor equal in value to the characteristic impedance of the line being tested (usually 50 or 70 Ohms).

If one does not have a suitable square-wave generator, the one shown in Fig. 6 is simple to build and very versatile. It utilizes a 7405 as an oscil-

lator and a 74S140 as an output/buffer. The square waves produced have the necessary fast rise time, and the 360 pF variable capacitor (a standard BC type) will allow varying the output frequency from about 300 kHz to 3 MHz. So a variety of transmission line lengths can be tested. The oscillator should be constructed in a metal enclosure and is simply powered by two 1.5 cells of either the C or D variety. The 27-Ohm series resistor from pin 6 of the 74S140 has already been chosen, in conjunction with the internal output impedance of the 74S140 section being used, to provide the correct terminating impedance for a 50-Ohm coaxial system. No further terminating resistor is necessary when the generator output is connected to an oscilloscope and a 50-Ohm coaxial line.

The use of a simple time-domain reflectometry setup to check an antenna system can prove to be of definite value, especially when swr readings give rise to doubt as to the condition of an antenna system. The usual swr meter reading is taken only at a definite point in the transmission line/antenna chain and it reflects conditions only at the point where the swr meter is inserted. Granted, the swr meter reading even at a fixed point in an antenna system is influenced by conditions throughout the antenna system. But there is no way to tell from the swr meter reading alone where a fault might have taken place in the total transmission line/antenna system. The oscilloscope display of the time-domain reflectometry method provides that extra dimension that makes locating a fault in an antenna system significantly easier. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 110

the factory . . . and the factory is in Japan, so rots of ruck.

If you've priced shipping charges lately, you know another reason why there is much to be said for buying from you local dealer. Normally, the dealer picks up the charges from the factory to his place. If you buy from a dealer who has no service, you'll usually have to pick up the freight charges to and from the factory service department . . . and figure two weeks for shipping (at least).

The article suggested getting bids for ham gear and accepting the lowest bid. Some hams have been using the WATS line numbers for this already. There has been a growing number of cases in which some crafty people have set up as dealers, published a WATS number, and undercut everyone else on price. As Barnum said, there's a sucker born every day. These "dealers" seldom have much in stock, but they "can get it for you immediately." The manufacturers tend to fill orders from the better paying dealers first and, if anything is left over, fill the orders from these operators last. This means you can easily go several months waiting for delivery, while the dealer has your money.

Getting bids on ham gear will quickly put you in touch with dealers who are waiting for you with "bargains." The markup on ham gear is very small to start with, seldom running more than 25%. It takes all of this to run a store, prepay for equipment, carry out warranty service, etc. For every percent you manage to cut off that figure, you are laying yourself open to getting screwed. The lower the price, the more the chance that you are the one who is going to take the licking.

Sure, a dealer operating out of his cellar or garage, with no gear in stock, no employees, and no service, can sell very cheap. But you have to wait for the factory to honor his order for a drop shipment direct to you. This means you pay those shipping charges. It also usually means extended waits, no matter what the promises were on the phone.

The dealers were more than a little upset over a ham magazine promoting cutthroat selling, a practice that could quickly drive legitimate dealers out of the ham business. In the longer run, it could encourage manufacturers to start selling directly to the ham, a practice which at first has the seeming benefit of cutting out the middleman and bringing prices down. The fact is that every experiment with this form of selling has forced prices right back up because customer service gets to be an ogre and the need for local dealers becomes imperative.

In general, the rule is that the more discount you get, the longer you may have to wait and the more of an orphan you'll buy when it comes to problems. If you have infinite patience and are equipped with a good test lab and a lot of experience in working with the latest equipment, it may be worth your while to shave a few percentage points off the purchase price. Good luck.

AVUNCULAR ADVICE

Newcomers to amateur radio have a lot of catching up to do. Frankly, it takes years of forgetting most of what you read and much of what you hear to develop the learned ignorance of many old-timers. You can hear them pontificating on 75m long into the nights, often operating in groups and thus reinforcing their misinformation.

Well, the esoterics of radioteletype and slow scan television are still mysteries to the beginner, perhaps awed by his own bewilderment and the appearance of mastery by hams heard over the air. Take heart, pre-Novice, all is not as it seems. The buzzwords of amateur radio will soon be yours to cow family and friends, and your gradual understanding of electronics will be both a delight and a temptation to one-up CBers.

It is difficult, when surrounded by the delights of modern electronics, not to try to skimp on fundamentals. A partial understanding of some articles in *73* can give people false security, which can cause great harm later on when the lack of understanding of fundamentals assures that nothing is really thoroughly understood. You need a firm foundation in electricity, magnetism, motors and generators, etc.

One of the purposes of the Novice Class FCC exam is to encourage people to study basics. The FCC exam series is very well designed to carry the beginner right on through the steps of understanding which will make it possible to deal with more advanced technical concepts. The *73 Study Guides* have everything you need to know to start from scratch and work your way up to mastering electronics to the level where you should be able to pass a First Class Commercial FCC exam . . . and certainly have no trouble with the Amateur Extra exam, even with some of the very tricky questions the FCC throws at you.

Yes, the FCC resorts to tricks. I get a lot of complaints about this and some would-be amateurs get so angry about it that they want to take the FCC into court. Unfortunately, this is a losing battle, for the FCC has a whole bevy of staff lawyers, so the whole thing costs them nothing. Further, judges tend to be very wary of going against the government . . . that's where their promotions come from. The government generally has to really screw things up before they can lose a case. This means that you'll have to endure the warped minds which put together the ham exams and just figure that you'll have to allow a 10% margin for FCC bias.

The best response to FCC trickery is to come to their exams as over-prepared as you can. Be sure that you can pass the code test in a breeze, otherwise you may still be uptight when you get to the written part of the ritual and not be able to throw your full weight into it. If there is any code course even close to giving you the confidence of the *73* series, I'm honestly not aware of it . . . and if I were, you can be sure that I would make the *73* tapes even better.

On tape number four of the *73* Novice theory series, I discuss the questions on typical Novice exams. If anyone who has used these tapes has ever failed the exam, this has been kept a secret from me . . . and I would find it hard to believe in the face of the thousands of enthusiastic letters I've received from survivors.

High Seas Adventure — Ham Style

— part IV

W6YO's odyssey ends, as the *Yankee Trader* finally returns home.

James E. Seidel WA6FEI
1066 N. Westside St.
Porterville CA 93257

Jules Wenglare W6YO set sail aboard the *Yankee Trader* from Freeport, the Bahamas, on February 15, 1977, for a ten-month around-the-world cruise. His westerly circumnavigation of the globe, his search for adventure in strange and exotic ports of call, and his operation of amateur radio, both at sea and on land, were partly covered in the last three issues of *73*. Now, here in part IV you will venture with him during the final seven weeks of the most enjoyable and exciting trip anyone could ever experience.

In the tape recording Jules made after leaving Cape Town, South Africa, he said: "The seas are picking up here. We're kind of rolling a little. Let's see . . . the weather is overcast with the wind blowing whitecaps. The swells are five to ten feet high. They are good size, but we haven't had any rough weather yet. Can't do much about it. It's 1700 miles to St. Helena, around seven to ten days, one of our longer crossings . . ."

Jules was looking forward to meeting the ZD7 hams when he arrived. He hoped to obtain permission to operate amateur radio from the island.

The bands were very good at sea, and he made many contacts. He talked to Mac ZS1LK, whom he had met back in Cape Town, and Gordon ZS2MI, on Marion Island. Another QSO was with Bill ZD7SD and Sybil ZD7SS on St. Helena. He requested information about obtaining a license, and everything seemed favorable.

The *Trader* arrived at Jamestown, St. Helena, at 6:00 am, Saturday, October 29, and Bill ZD7SD, who was born on the island, came aboard to meet Jules. Later, they went ashore and headed downtown to a government office. Jules filled out some papers, and the governor's secretary asked him what call he would like to have. ZD7YO, of course. It took about a half hour, and the call was issued. The actual license was picked up later after having been signed by the governor of the island.

Jamestown is a very quaint and old rustic city with all the charm one would expect. Bill's home was located about 800 feet up the side of a mountain. "What a view," said Jules.

"You look out right over the ocean, back about a half mile, but at a fairly steep angle."

They hooked up Jules's equipment (along with Bill's rig) and set everything up for split frequency operation. The bands were checked but nothing was coming in, so they went for a sightseeing ride in the country. Jules said, "It was very beautiful—all lush and green here on the southern half of the island."

They later went back to the *Trader* and, for Bill, Jules got the fiberglass poles and spiders for the quad antenna I mentioned in part I which never got installed. They returned to Bill's home and got on the air. The first contact was with Rudy W3CXX at 1903 UT (7:00 pm local time). The fifth contact was with John W6UZ, back in good old Delano, Jules's hometown.

One of the contacts made was with Archie K4IBO, Miami, where Jules had stayed a couple of weeks before this world trip began. "It was really something," Jules commented, "to work Archie. First time since somewhere in the South Pacific. It was really a surprise."

Jules worked many friends, both on 15 and 20 meters. Most of the contacts were on SSB during the CQ DX contest—mostly split frequency, but some transceiver operation. At times, the bands didn't open up very well and no contacts were made. He did make close to 300 contacts as ZD7YO, with the final contact at 1613 UT the following day: a PY1. It was another successful ham operation from a country where he had less than 36 hours to visit.

One of the places he visited was what they call "Jacob's Ladder." He climbed to the top of this 699-step stairway that goes straight up from Jamestown on the side of a hill. It's really steep and was built years ago. The ladder is very famous, with cement steps about 10" high and a cast iron plate for railings and sides. "It's all bolted down to the solid rock hillside," Jules said, "at about a 45-degree angle."

Jules said it was quite a climb, but he and another *Trader* passenger went all the way to the top after a few rest stops. He said that the local boys slide down the rail. It was really a sight to see.

Bill took Jules to Napoleon's exile home. They went through the garden and the five or six room home and saw the room where Napoleon had died. A French flag flew inside the compound there on a British island. Jules said that this could be classified as a new country under the circumstances. The five-acre historical sight belongs to France exclusively, as a tribute to Napoleon.

Jules finally had to leave St. Helena, and Bill and Sybil bid him farewell at the dock as the air horns aboard the *Trader* sounded. Jules said, "It was another memorable stop. One of the rare islands of the world."

The day after leaving St. Helena, it was Halloween. Many of the passengers aboard the *Trader* dressed up in all sorts of attire. One young lady was dressed up as a "gas pump." She had a large paper bag with numbers painted on it slipped over her head, and carried a black hose around to simulate the hose and nozzle of the pump. Many unusual costumes were worn to celebrate Halloween.

The bands were pretty good about four days out to sea. Jules worked Dixie KG6JIO and Dave KØWIQ/DU2 (Clark AFB, the Philippines), and Father Denny P29CC even arranged for them to work ZD7SD for a new country. He had some tremendous signals coming in, with some good openings.

Remember the around-the-world yacht race I mentioned in part III? Well, Jules wrote another short piece about it for issue #10 of the *Trader Tales* newsletter.

"The *Yankee Trader* could have been taken as the 'mother ship' of the world's most elite bluewater racing yachts competing in the Whitbread Round-the-World while all were resting in Cape Town.

"The racers are sailing in an easterly circumnavigation, while we are cruising westerly. Our paths will 'cross' in the Atlantic, off the eastern tip of Brazil.

"The Traderites met the crew members of the sleek yachts while bending elbows at one of the finest yacht clubs in the world. This famous world yacht race started at Portsmouth, England, August 27, and

Photos by Jules Wenglare W6YO

Left to right: Bill ZD7SD and Sybil ZD7SS on St. Helena Island, with Jules W6YO. Jules operated here as ZD7YO for a short but successful DXpedition.

will end there sometime in April, Cape Town being the first of three stops. The second leg is expected to be the roughest, crossing the southern Indian Ocean to Auckland, New Zealand, in an area known as the 'Roaring Forties,' so close to the Antarctic that they may encounter icebergs. It is interesting to mention that their main communications are dependent on amateur radio 'ham' operators. Aboard the yacht *B and B Italia*, crew member Henry and his station I2NSX have been in contact with several hams—mainly with Gordon ZS2MI on lonely, isolated Marion Island, which South Africa staffs with a small group of weather professionals and one radio operator. This station will furnish the yachts vital wind directions and iceberg warnings.

"Gordon and Henry asked for my assistance in relaying weather and position reports at times when they could not copy each other (and I could) while we were heading to and away from St. Helena."

It was a pretty smooth crossing to Recife, a big seaport on the eastern tip of Brazil. Upon arrival, Jules called Fred PY7AZQ in Olinda, a nearby town, and made arrangements to meet him at the dock. Well, something happened and Fred didn't make it.

Sometime later, Jules took a bus to Olinda in hopes of finding him. No such luck; he couldn't find the house. On the way back to Recife by bus, he saw a ham antenna, got off the bus, and checked the house only to find that no one was there. He showed Fred's address to a cab driver, and about five minutes later the cab pulled up in front of Fred's home. The only one there was a babysitter, so Jules left a note for him and returned to Recife.

The following day, Fred, his wife, and daughter came to the ship and met Jules. They all took a taxi back to Fred's home for a visit. While there, Jim PY7BXC and Xavier PY7DA came over to meet him. He had a very enjoyable stay.

Jules was invited to a breakfast the following morning to celebrate a very special occasion. It was to do honor to Vic PY7AN, who was celebrating 40 years as an amateur radio operator.

Jules met Alex PY7PO when he was picked up at 5:30 am Saturday and taken to the special celebration. When they arrived, a large crowd had already assembled. "There were about 15 to 20 people there," Jules said. "One fellow was shooting off skyrockets. Boy, did they go off with a big bang way up high. There were 40 of these rockets. One for each year." Jules also mentioned that two buglers were playing to add a little extra color to an already happy event.

Jules saw Vic's ham room and setup. He had a number of awards and certificates on the wall. The antenna was rotated with a car steering wheel, as the turning shaft went straight up through the roof.

Another location visited was the local radio club, where Jules met a few more hams. The club had a nice station set up, with a large number of QSL cards on display. He said he was only there for about an hour.

One of the more interesting visits was at the home of Plinio PY7ACQ, a very active ham. "He went four times to Fernando de Noronha Island (PYØ), and made two trips to St. Peter and St. Paul's Rocks (PYØ). Just amazing. That evening he showed us 8 mm movies of them."

The films Jules saw showed the difficulty of getting on these rocks and setting up a ham DXpedition. He said it was a very good presentation. It was the first official ham operation from the rock islands (where they had to operate under pretty poor conditions). "It was an endurance check, that's for sure," commented Jules.

After a week of extensive activity in Recife, the *Trader* set sail at about 7:40 am on November 14. "I got on the air," mentioned Jules, "but there wasn't too much to work yet. I finally did have some contacts later that afternoon and evening. Even handled a few patches the first night out."

A couple of contacts were made with hams in Trinidad. He lined up some meetings for when he arrived. It's always nice to have talked by radio with someone you've never seen before and then meet him in person a few days later.

The seas were very smooth and calm almost all the way to Trinidad. Several of the passengers even saw a couple of extremely large killer whales. They came very close to the ship, and estimates were that they were over 30 feet in length. It was another acrobatic show at sea.

Remember those three novice students I mentioned Jules giving code practice to? Well, the birth of three new "ham" operators was reported by him.

Jules had Russell W4LAS in Virginia Beach send three tests to him in Recife. He picked them up at the post office and reported that Ted, George, and Roland passed their code test while crossing the Atlantic, and took their Novice FCC exam between Recife and Trinidad. Hopefully, all three received their ham tickets.

The *Trader* anchored in Trinidad late in the afternoon, quite some distance out in the harbor. On shore, Jules called Mike 9Y4UA, who works at the U.S. Embassy. He later went to the Embassy and met Mike and another ham from Caracas, but he doesn't remember his call. He also met Rusty 9Y4RH, whom he had talked to on the air.

"Mutiny on the Bounty" in 1789—and the resultant children of mutiny on Pitcairn Island—was fact. Ask Tom Christian VR6TC. Captain Bligh with the Bounty's breadfruit cargo never arrived in the West Indies. Captain Bligh and HMS Providence, *loaded with breadfruit plants, did—some fours years later, as the plaque and tree indicate, here on St. Vincent Island.*

Jules spent Thanksgiving Day on Trinidad, and talked amateur radio while enjoying lunch with Carl 9Y4OV and Rusty. Thanksgiving dinner was very well enjoyed aboard the *Trader*. It was a complete turkey dinner with all the trimmings.

About a half-hour drive from Port-of-Spain is the Omega Navigational Aid Station, which Jules visited. It is on 10.2 and 13.6 kHz. The antenna system is strung across the valley between two 1000-foot peaks.

From the left are Alex PY7PO, Jimmy PY7BXC, Plinio PY7ACQ, Vic PY7AN, and Jules W6YO. These are only four of the many hams Jules met during his visit to Recife, Brazil.

Jules said it is a reasonably nice transmitter setup, "coaxfed with large vacuum relays which switch the resonance of the antennas from one frequency to the other by a difference of 3.4 kHz. They have huge 20-foot diameter coils with motor-driven slugs to keep the antennas tuned. Stations like this are in Norway, Liberia, Hawaii, North Dakota, Reunion Island, Argentina, and Japan, in addition to this one on Trinidad."

The *Trader* set sail for St. George's Grenada Island on November 26. The following day, the ship arrived, having gone a distance of 103 miles.

On Grenada, Jules visited an old telegraph museum display. There was a tape show showing how telegraph messages were sent. He said, "There were two keys side by side, which were used to send the code. It was very interesting."

He met Leroy J3AI at a restaurant and then visited his home overlooking the harbor.

After a very short stop, the ship left for Carriacou, an island north of Grenada. While here, he said he ate an apple that had fallen from a tree. He only took a couple of bites, and soon after, his mouth and throat began to burn. Someone told him later that the apple was poisonous. This toxic apple has been known to be fatal to small children.

His throat was really burning by the time he got back to the ship. "It felt like I had drunk Tabasco sauce," Jules commented. It was about three days before his throat got back to normal.

The trip from Hillsboro, Carriacou, to Kingstown, St. Vincent Island, was made in about six hours. While sailing there, an event took place which many people would like to accomplish: The *Trader*, along with her passengers, crossed their outboard course at 0430 hours on November 30, 1977, and had now circumnavigated the globe—a sail of 29,346 miles in a little over nine months.

While on St. Vincent, Jules met and went to the home of Bill VP2SQ. His radio shack is built on top of his home. While checking his log, Jules found that Bill had just recently worked Frank W6KPC on 15 meters, as well as several other hams Jules knew personally. He said that Bill also worked 2 meters and on occasion gets into Trinidad, over 100 miles away.

It was in the year 1787 that *HMS Bounty* left England bound for Tahiti to collect and transport breadfruit plants to the West Indies. It is history that there was continued abuse and almost brutal treatment of the crew by Capt. William Bligh.

Some 16 months later, on the morning of April 28, 1789, with the *Bounty* laden with over a thousand breadfruit plants, the 23-year-old Master's Mate, Fletcher Christian, and a number of the crew mutinied against Capt. Bligh. Bligh and eighteen loyal seamen were cast adrift in an open boat and managed to sail that overladen craft 3,618 miles over almost uncharted waters, reaching the island of Timor in 41 days. Fletcher Christian and his fellow mutineers threw all the breadfruit plants overboard and sailed back to Tahiti.

Mr. Christian, along with eight other mutineers, six Tahitian men, and twelve Tahitian women, sailed the Pacific in search of a secure home. On January 15, 1790, they located and went ashore on uninhabited Pitcairn Island. This island, nearly two centuries later, is now the home of Thomas Coleman Christian VR6TC, great-great-great grandson of Fletcher Christian.

Captain Bligh eventually returned to England, and a few years later completed his task and transported breadfruit plants to the West Indies. Here on St. Vincent, Jules saw a breadfruit tree that grew from a shoot planted from an original plant brought there by Captain Bligh after the mutiny on the *Bounty*. There is a plaque in front of the tree telling of its origin.

Bill took Jules sightseeing all around the island. After a very enjoyable day together, Bill took Jules back to the dock and they bid farewell; the ship was scheduled to leave shortly.

The trip from St. Vincent to Dominica was made overnight. When Jules arrived, he met Austin VP2DAJ. Jules had talked to Austin some nine months earlier via amateur radio when the *Trader* was in this area at the beginning of its world cruise. Their eyeball QSO was short due to the fact that Jules was on the island only one day. Jules took in a few of the sights and went back to the ship.

On Friday morning, December 2, the *Trader* anchored in English Harbor, Antigua. After Jules went ashore, he saw some more of those small apples that had caused him so much misery. This time he only looked.

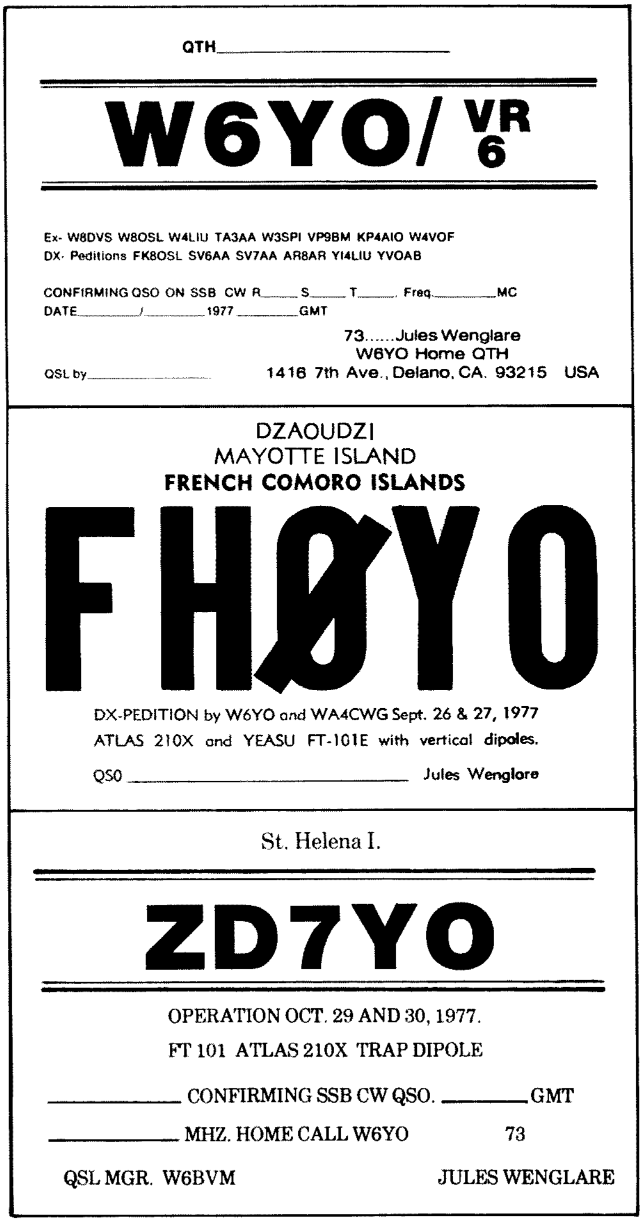
While walking around,

Jules saw a triband beam and inquired at the home. It was the residence of Jim VP2AB, who invited him in for a visit and a look at his ham room.

Jim later took Jules out of town about ten miles to see a high-powered shortwave broadcast station, a very modern up-to-date station only about a year old. Jules was given a tour of the station by Bob VP2AZB. He was there for about three hours.

The *Trader* left the island of Antigua about midnight, after a twelve-hour visit, and headed for St. Barthelemy Island (St. Bart's). The ship arrived shortly after Jules got off watch.

In the harbor was the *Polynesia*, a four-mast windjammer of Windjammer Cruises. This is one of the ships that takes one-week cruise tours into the West Indies.



Of the 53 stops Jules Wenglare W6YO and the Yankee Trader *made, three locations issued him a license to operate amateur radio. The first was on Pitcairn Island (VR6). The second was Mayotte Island (FHØYO), followed by St. Helena Island (ZD7YO). With these special calls, he made over 900 contacts, thanks to the countries and the officials who appreciate amateur radio and made it possible.*

Jules didn't do much here other than look around and take pictures. He said, "I just sat under a nice shady tree and admired the beach and everything about 150 to 200 feet down below. There was a group of boys and girls playing with a frisbee down on the half-mile-long beach. It was very peaceful up there . . . "

The ship left that afternoon and arrived at St. Martin Island that evening for a two-day stay. While walking in town, Jules saw what at first he thought was a rotary dipole. "It seemed funny with traps on it," Jules said. It turned out to be a triband antenna. The director and reflector had come off during a windstorm. He inquired at the home, but the ham wasn't in.

Jules said, "This was the first place I saw with big American cars. I saw more Cadillac and Lincoln taxis than I have anywhere in my life. Amazingly, they were all new ones!"

Jules mentioned that on these islands camera film is very expensive, about $10 for a roll of 110 or 35mm. So, if you happen to be making plans for a trip into this area, take along a good supply of film—or money.

Jules met Vince PJ7VL, who works at the weather station on St. Martin. He knows many of the hams Jules knows. They even had a chance to get on the air for a few stateside contacts on Vince's rig.

The following day, Jules had a cold, so he stayed aboard ship. There wasn't much else to see ashore, so he just relaxed a little.

The *Trader* left that evening, and the following day tied up to a buoy at Saba Island. With only a few hours there in port, Jules couldn't do much. A quick tour of the area and back to the ship. The next stop was the island of Tortola in the British Virgin Island group.

While at sea, Jules got on the air and talked to John 4S7JD in Sri Lanka, the ham he met back a few months ago. He also worked into ZL-land and talked to several old friends in California.

They finally arrived at Road Harbor, Tortola, on December 7. Jules took a cab into town, where he met Art VP2VJ, the radio inspector for the island. During their conversation, Jules asked, "Is it any trouble to get a license here?" Art said, "No, you want one now?" He said Art just started to fill out the papers for him. Jules was issued the call of VP2VEF.

Art told Jules that Bob Denniston WØDX, ex-ARRL president, now VP2VL, owns the Smuggler's Bay Inn here on the island. Art tried to get ahold of Bob by phone, but couldn't locate him. After Jules returned to the *Trader*, he had some visitors. Art had finally located Bob, and they came aboard for a visit.

Jules met Bob over 20 years ago and had even worked him on the air from Crete and many other places in years past. They all talked about DX and the old times during their visit in Jules's cabin.

When Jules got on the air as VP2VEF, the first contact was with Ed W7ZJ, a friend of his. Jules heard him on the air and gave him a call. He was told to "stand by." Ed was very surprised when he found out that it was actually Jules W6YO.

After the *Trader* stopped at one more island, St. Thomas Bay, Virgin Gorda, she left the area and headed for the Bahamas. Jules said, "On our way we crossed right over the Puer-

to Rican Trench, the deepest place in the Atlantic Ocean, nearly five and a half miles deep. As we passed the eastern reaches of the Grand Turks Islands, we had sailed 30,000 nautical miles.

"We were enjoying nice warm weather all along for months on end, it seemed. While listening to the radio news, we heard that the east coast was having blizzards and subfreezing temperatures. Then, on December 11, southeast of San Salvador, where Columbus made his first landfall and where we had hoped to visit for the second time, we were hit by a weather front that made us shiver. The storm that followed for two days kept things sliding off the tables at meal times and made walking difficult anywhere. For the second or third time on the trip, the ladies were missing their meals.

"Since leaving the Virgin Islands, it was great to make final contact with 4S7JD, VK4MW, ZS1ER, ZD7SD, 9Y4OV, and even Helen HC2HV, all of whom we had 'eyeballed' along the trip. Our contact with the ship's doctor's daughter, Jay WA2JBY, was achieved after many attempts and frustrations.

"We arrived in the busy port of Nassau on the morning of December 12. There were two large cruise ships in, and we were hardly noticed among the crowded shopping streets of a colorful city.

"Again, I mailed off over 20 copies of the *Trader Tales*, our monthly newspaper, to friends around the world and in the States.

"I did find a ham, Verne C6ANR, ex-VP7NR, who runs a nice men's clothing shop in town." The ship departed on the second day and headed for Freeport, the Bahamas, where, Jules said, "We arrived at 1400 zulu on the 14th of December, the place we departed 303 days ago . . ."

Jules said, "It was most gratifying to get all the weather data, phone patches, and just FB QSOs with so many hams around the world. The maritime mobile and other nets who give priority to sea-going hams certainly are a wonderful group of 'hams.' I've realized that this is the best system of communications for the smaller ships and yachtsmen.

"To get back to the U.S. mainland with all my gear, I was fortunate to have arranged over the air to sail back in a small luxury sloop of one of the passengers who only went as far as Singapore, but now was waiting in Freeport to pick up his many souvenirs and diving equipment left on the *Yankee Trader*.

"Three of us from the ship, with our belongings–one fellow had an 18-foot outrigger canoe from Tahiti–left at 4:00 am and hit strong head winds all the way to Bimini. We were constantly getting spray all over us up on the deck where we all took two-hour 'wheel watches.' After a needed rest in Bimini and some spearfishing for lobster and a good dinner, we set sail across for Miami, still going against strong winds and rough seas.

"It was great seeing the bright lights of Miami Beach reflecting on the horizon. We arrived practically at downtown Miami at 11:00 pm, where our skipper called the customs and immigration people, who came right over.

"I finally wound up packing close to 500 pounds of souvenirs, clothes, radio gear, and related stuff at the QTH of Bill WA4VOI, who was one of my main contacts around the world."

Jules shipped his belongings by truck back to California and caught a plane himself. He arrived at his home in Delano on the evening of December 23, 1977, and was warmly greeted by his wife, Lyla. Christmas came two days later.

Jules had planned on taking Lyla with him on this world cruise, but she decided that he would have more time for amateur radio activities if he went alone. They kept in contact with each other with phone patches provided for Jules by other hams. While he was gone, her sister came all the way from Australia and stayed with her for a very long vacation. Lyla is also from Australia.

I spent many hours with Jules going over the manuscripts for this article and selecting the many slides used for the photos to go with it. I only wish that every piece of information he gave me could have been used here in print, but unfortunately they all couldn't. I tried to hit the highlights at each stop and bring out the most interesting activities. I sincerely hope I did justice to such an extraordinary adventure.

I asked Jules a few questions about the trip which were not covered in any of the tapes. Here are part of the answers.

Of the 1,070 hours on Jules's transmitter's hour meter, he averaged 3½ hours each day while at sea. He spent 163 days in port (53 stops) and 139 days at sea. There were 3,600-plus QSOs, of which over 900 were made while on shore. He had over 125 "eyeball" QSOs with other hams on every continent of the world.

What location was the most enjoyable? "Cape Town, South Africa." He said the cleanest spot was the "Maldives." Of all the hams he met, the three that top the list were (and I'll put these in alphabetical order) Tom Christian VR6TC, Pitcairn Island; Father Dave Reddy CEØAE, Easter Island; and Bill Stevens ZD7SD, St. Helena Island.

Jules sailed 30,759 nautical miles aboard the *Yankee Trader*, a tough, rugged, and highly seaworthy vessel. The *Trader* was built in 1930 by the Spear Engineering Co., Norfolk, Virginia. It was originally commissioned by the U.S. Coast and Geodetic Survey as an oceanographic research vessel. Her original name was the *Hydrographer*. She has assisted in charting the world's major bodies of water, including the Arctic and Antarctic Oceans. During WWII, she served in the Pacific. When a new oceanographic research vessel was built in the mid-60s, she was renamed *Yankee Trader* and converted to become part of the Windjammer fleet.

Constructed of nickel iron, the *Trader* is considered to be an exceptionally strong, stable vessel. She has twin diesel electric engines generating 1500 hp each. She has a single screw (propeller), 11 feet in diameter. Her registered tonnage is 1180. Her cruising speed is a variable 10 knots, with a range of 18,000 miles.

To embark on a 10-month around-the-world cruise to strange and exotic ports of call is true adventure. If you take amateur radio and put the two together, you have the greatest sea experience and personal search for adventure ever possible. I experienced this great adventure when I wrote about it. You went along while reading it. But for Jules Wenglare W6YO, the experience was reality, for he took amateur radio aboard the *Trader* with him and lived it—at the four corners of the globe. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 181

WHAT SHOULD YOU BUY?

One of the curses which can drive a beginner to drink is the reluctance to spend a lot of money on equipment. The result of this is that many Novices get on the air with junk and find amateur radio a terrible experience. They have trouble separating signals and lose contacts to interference a lot. The obvious answer is to spend a little more and get something first rate in the way of a receiver.

You don't have to buy new equipment, but, on the other hand, you'll regret it if you go too far back and load up with an old tube-type receiver. Moderation is the watchword... old, but not too old. Just about any rig with solid state except for the final transmitter stages and made within the last ten to twelve years should provide you with a usable station. Get the very best you can, so you don't have to cope with drift, adjacent channel garbage, wide i-fs, etc.

Not to put flea markets and auctions down, but I seldom see anything I'd recommend buying at these low-end debris exchanges. Oh, you *can* luck out, but I look more for gadgets and parts at these affairs than for rigs. A better source of a rig is to join the nearest ham club and let the members know you are in the market. If it is any size club, some of the members will be wanting to update their shack with the newest gear and be looking for a good home for their old stuff. This means you'll have a better handle on the history of the equipment and probably some help in service when the inevitable happens.

Another possibility is your nearby ham dealer. Now I don't necessarily mean for you to run down and shop from the used ham gear shelf, which is probably rather scantily occupied most of the time. Used equipment doesn't last long in a store. I suggest you check over the used gear to see if they have what you really want. If not, talk with the owner of the store and explain what you are looking for and suggest that he keep an eye open for it as a trade-in on some new gear. This can be to both your and his advantage. If he knows he has a good fast sale for something, he can offer a little more for it ... and he won't have to mark it up as much since it won't be taking up space and costing him money to keep in inventory.

But what about the ads in ham magazines for used equipment where hundreds of old sets are advertised? As far as I know, this is more of a come-on than anything else. Your chances of actually finding one of those advertised rigs in stock is slight. One more warning, while I'm at it. I had a chap working for me one time who had been with one of the major ham stores. He swore that the equipment which they had been selling as "reconditioned" went out of the store without ever being plugged in to see if it would work.

WHAT ABOUT THE CODE?

One of the more unfortunate aspects of the Morse code is that it is mandatory for a ham license. If a knowledge of the code were optional, I'm convinced that a lot more hams would use it and enjoy it. But, since there is no choice, don't let the code be a big deal... it isn't, if you manage to get started the right way.

There are some incredibly bad systems for learning the code. Sams had probably the worst I've ever seen... the sight and sound method, I think they called it. I wonder if anyone ever managed to learn the code with that. The age-old ARRL system of gently increasing speeds has lost us hundreds of thousands of prospective hams. If it hadn't been for the Sams system, I would make the claim that it would take a truly deviant mind to come up with a more frustrating and failure-prone system for teaching the code than the ARRL has been pushing for about 50 years.

Some recent experiments with students starting with high-speed code have confirmed earlier tests. The fact is that it takes very little longer to start right out at 13 words per minute than at five. In fact, there are more and more students starting out at 20 words per minute and able to pass the FCC exam with just three or four days of intense practice.

Four-year-old kids, barely able to write, even in block letters, have been passing the code test. How many of you are willing to admit that a four-year-old can outperform you... even a *smart* four-year-old? Learning code has nothing to do with brains, as you'll discover when you meet a few hams and find out what a wide range of intelligence is involved. Some hams may have been a little hard of hearing when brains were handed out and said, "Trains? They make me sick... no, thanks."

The code system that works the fastest and will give you the confidence you need to beat the bastards is on the *73* code cassettes. I dislike putting in that commercial, but I guess it's necessary because every now and then I talk to a club where they are using the ARRL materials and driving people crazy. It just isn't fair ... and being an ARRL-affiliated club doesn't mean you have to take it out on defenseless students.

ANTENNAS

Until the day comes when you go the truly practical route with a 73-foot tower and a good quality three-element beam ... and find that you have a signal into any spot in the world where a DX operator chances to pop up ... you'll go through what most of the rest of us have—continual experimenting with various antennas. Sure, the tower, rotor, and beam are expensive... and it will spoil all the fun of being ground into dust in DX pileups, of losing contact in the QRM with that 50th state just as he was about to get your call letters ... and of other growth-promoting traumas. Perhaps you won't really appreciate a good antenna system unless you apprentice with dipoles, longwires, and such for a few years.

Not that dipoles are all that bad on the lower bands. You can get a dipole to plunk a signal almost anywhere in the world if you put it in a good spot and then fill it with a good solid signal. I had the thrill of hearing my own dipole putting through an S-9 signal into Australia on 75 meters one night while I was operating from VK3ATN. *That* was exciting!

YOUR EXPERIENCES?

It's been a long time since I first braved the ham bands... and they were sure different then. With very few exceptions, everyone had to use crystals for frequency control, so the standard mode for operating was to go on the air, call CQ, and then tune the band for a call. Forty meters was a CW band, but then about 90% of the ham contacts in those days were made on CW. The 100 kHz wide 20m phone band was pretty well filled up with big signal stations... and a phone kilowatt in those days cost on the order of $20,000, so you didn't casually buy one. The other Class A phone band was 75m and it, too, was pretty well taken up with about six or seven nets of kilowatt phone stations. The band was 100 kHz wide and each net took 10 kHz of this, leaving very little for the 50-Watt average ham.

The great unwashed hung out on 160m... the Class B band. There were no commercial transmitters then, so most rigs were copied out of *Radio* magazine or *QST*. *Radio* had the better projects by a wide margin.

How about writing about some of your own experiences? I'll bet you've had some which would strike a familiar cord with other readers. And perhaps you have some good advice on rigs, antennas, QSLing, etc.

ARRL VS. WOMEN

A couple of months ago I brought up the matter of Mary Lewis W7QGP and her battle with the League. Mary was disqualified for the post of SCM unfairly, she thought, so she took the League to court over this. The real battle seemed to be over Mary's threat of becoming the very first woman director of the League. She is the only person running against the incumbent Thurston. The League position has been clearly explained to Mary: No way will there ever be a woman director.

Mary won the first big battle when the case came up in court and the judge ruled 100% for Mary. Firstly, he said that the League should have charged Mary for the mailing list if that was a problem, and should not have disqualified her for the post of SCM. Then he went on to say that the League should stop stalling on the director election and proceed with it. The League maneuver on this apparently was to postpone the election as long as possible, allowing their yes-man Thurston to remain in power in the interim.

My mail has been heavy with compliments for Mary and badmouthing for Thurston, who apparently has given a great many Pacific area hams the idea that he holds them in great contempt. Every one of the readers has asked not to be identified for fear of reprisals by Thurston or the League.

If we should lose amateur radio next year, we will have only ourselves to blame for permitting directors like Thurston and his ilk to refuse to put capable people into office at HQ.

RTTY Loop

from page 14

nections. This figure shows you how to do it. This point is also useful for those of you working on computer transmitting routines who have to key the loop from the computer.

Now, as mentioned, this is far from an ideal way to produce a string of RYs. In fact, since the need arises to automatically send text like "THE QUICK BROWN FOX JUMPED OVER THE LAZY YELLOW DOG 1234567890 TIMES" (the sentence containing all letters of the alphabet for those of you who just joined us), or IDs like "DE WA3AJR," it would be nice to have a circuit that could be set up to put that out. A block diagram of such a circuit is shown in Fig. 4. What we are going to do is encode what we want to send on a diode matrix, and then put it out using parallel-to-serial conversion. I know, you all are saying, "There he goes with that computer stuff again!", but I promise, no computer. Everything we will do will be with hardware, and I hope to explain it well enough that it is clear. If not, it's my fault! We'll get into it next month.

Turning to the *vox populi*, we'll take some overseas correspondence this month. Sgt. Gary Kohtala HL9TG/WA7NTF is looking for information in general on RTTY. Well, Gary, that's what we're here for. While you're stationed overseas, you may want to look into the MARS program. This has been a particularly fruitful source of RTTY gear for the ham in the service, and many a serviceman has come into amateur radio through contact with a MARS station. For those of you who don't know what I'm talking about, MARS is the Military Affiliate Radio System, and, while it is not as active as it was during the Vietnam "conflict," many hams still maintain regular net schedules to keep up the morale of our servicemen across the globe. Much of the traffic handled is on RTTY, only they call it RATT, and equipment is frequently available to the amateur willing to invest a small part of his time and get a big return—in more than one way.

Bernard Malandain 3D2BM writes that his Model 28ASR is equipped with downshift-on-space, a feature that is annoying when trying to copy groups of figures in weather broadcasts. Although he has studied the manuals, he states that he is unable to disable this function. Well, Fig. 5 is reproduced rather loosely from the Teletype Corporation's manual for the 28, Volume 1, Fig. 5-56. You can see that tightening the disabling screw will prevent the pawl from engaging the function lever and prevent downshifting-on-space. If this is not clear, at least I have pointed you in the right direction. Bernard also needs information on synch gears for the 28 to run on the 50-Hz current they have there, and the 84018 and 84019 gears for his Model 15 on the same current. Readers with information may write me or send it to him, at Box 590, Suva, Fiji.

Several readers have written with questions regarding the new Microlog RTTY units. The October, 1978, issue of *73* carried a nice review by K3CMY of his unit, and I will refer you all to that article for details. I met with the makers of the unit about a month back and had a chance to see it In action. Very impressive! Unfortunately, the data they were going to rush me has not materialized as yet, so I can say little other than what I have gathered by talking to users of the system. One problem that has cropped up in one station was rf overload of the device, shutting it down when the transmitter was keyed. I don't know if this is swr- or frequency-dependent, but I would be on the lookout for this sticky wicket.

Next month, we will look into the circuit for sending that RY or BROWN FOX painlessly, and maybe even understand how it works. Meanwhile, I look for your input to tell me what you want to see in RTTY Loop!

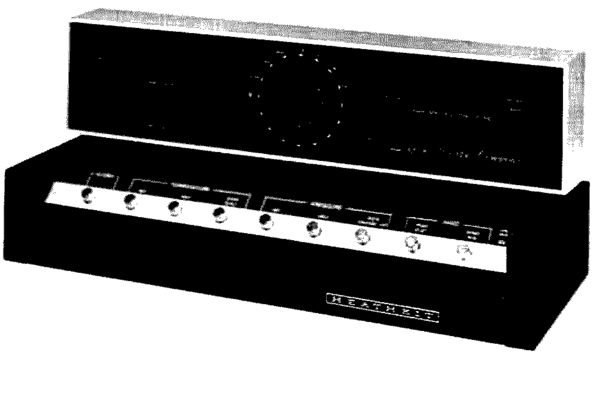
HEATH ANNOUNCES FIRST COMPUTERIZED WEATHER STATION

Heath Company, the world's largest manufacturer of electronic kits, announces the availability of its new ID-4001 computerized weather station. The microprocessor-based ID-4001 indicates time, indoor and outdoor temperatures, wind speed and direction, and barometric pressure on an upright display panel utilizing large LED readouts. It will also display average wind speed and automatically calculate wind chill factor as well. The ID-4001's memory allows instant recall of date and time of maximum and minimum temperatures, date and time of wind gusts, and the date and time of maximum and minimum barometric pressure. It can even indicate the barometric pressure's rate of change per hour and tell if it is rising or falling. The ID-4001's 6-digit time/date display shows time in hours, minutes, and seconds, and the date in month and day. The time/date can be displayed alternately, or either may be displayed continuously. The 12-hour time format has an am-pm indicator. A 2-digit display shows wind speed in mph, kph, or knots. A 16-indicator wind vector display identified by compass points and radial degrees indicates wind direction. The thermometer display indicates indoor or outdoor temperature in degrees F or C with + or − signs. A 4-digit display shows barometric pressure in inches of mercury or millibars. Separate indicators show rising or falling pressure. Kit and assembled versions of the ID-4001 are available.

For more information about the ID-4001, send for a free copy of the latest Heathkit catalog. Write *Heath Company, Dept. 350-730, Benton Harbor MI 49022.* Reader Service number H5.



First computerized weather station from Heath.

NEW 2 METER FM MOBILE TRANSCEIVER WITH MEMORY FEATURES OPTIONAL MICROPROCESSOR CONTROL UNIT

The TR-7600 2 meter FM mobile transceiver with memory, and an optional RM-76 microprocessor control unit, which provides six memories and various scanning functions, have been introduced by Trio-Kenwood Communications, Inc.

The TR-7600 provides full 4-MHz coverage (800 channels) on 2 meters and includes a memory channel. It operates on simplex (same transmit and receive frequencies) or repeater (plus or minus 600-kHz transmitter offset) modes. Furthermore, the memory can be used to provide a transmit frequency for accessing a repeater with a nonstandard frequency pair.

The TR-7600 also features a digital frequency display with large, bright, orange LEDs. Another LED, called an "unlock" indicator, shows transceiver protection when the frequency selector switches are improperly positioned or the PLL has malfunctioned. Selecting frequencies with the TR-7600 is fast and easy with its dual concentric knobs, 5-kHz offset switch, and MHz selector switch.

Power output is switchable between 10 Watts and 1 Watt (adjustable from 1 to 10 Watts). The TR-7600 is ideal for mobile use and comes with the MC-30S noise-canceling dynamic microphone. The compact transceiver measures only 6-7/16 inches wide, 2-7/16 Inches high, and 9-3/16 inches deep.

The optional RM-76 microprocessor control unit allows the TR-7600 to perform many interesting new functions. Using the RM-76 keyboard, the amateur can select any 2 meter frequency (including MARS on 143.95 MHz simplex), store frequencies in six memories, automati-

Jan 1979

The Kenwood TR-7600 2m mobile transceiver.

cally scan up the band in 5-kHz steps, manually scan up or down in 5-kHz steps, set lower and upper scan frequency limits, scan for busy or open channel, reset scan to 144 MHz, stop scan, cancel scan (for transmitting), and select repeater mode (simplex, plus or minus 600-kHz or 1-MHz transmit frequency offset, or one memory transmit frequency).

The RM-76's digital display indicates frequency (even while scanning) and functions (such as autoscan, lower scan frequency limit, upper scan limit, error, and call channel).

The TR-7600 was scheduled to be available by late November, 1978. The RM-76 microprocessor control unit will be available by the end of January, 1979. *Trio-Kenwood Communications, Inc., 1111 West Walnut Street, Compton CA 90220.*

MIRAGE B108 VHF POWER AMPLIFIER WITH BUILT-IN RX PREAMP

Mirage Communications is proud to introduce its new 2 meter solid state amplifier—the B108.

The B108 represents a new generation of all-mode amplifiers for VHF use. It incorporates operation features that have not been available before in a single amplifier.

The B108 is designed to operate on AM, FM, SSB, or CW, with a power output of at least 80 Watts for 10 Watts input.

A built-in receive preamp is standard. The preamp utilizes a J310 FET in the latest low-noise circuit design. It provides at least 10 dB of gain and a 2-2.5 dB noise figure. The preamp may be operated with or without the power amp being turned on.

Also standard is a rear panel connector, providing remote control operation. An optional remote head, the RC-1, is available with either a 6-foot or 18-foot cable.

Keying is provided by the internal rf sensing circuit, or the unit may be keyed from the external transmitter.

For SSB operation, the relay dropout delay is fully adjustable.

The B108 will strengthen the transmitter output, providing crisp, clear communications. The built-in receiver preamp will really help pull in the weak signals.

For further details, contact your local dealer or *Mirage Communications, PO Box 1393, Gilroy CA 95020, (408)-847-1857.* Reader Service number M75.

Mirage's B108 VHF power amplifier.

TELE-TOW'R BREAKOVER MODEL 55 TOWER

My impression at first sight of the Tele-Tow'r Breakover Model 55 can be expressed in one word:unprepossessing. And that's precisely what I was looking for!

While it may be mighty nice to have a couple of 120-footers with big monobanders on top in the backyard, I've never been fortunate enough to live where I could get away with putting up anything like that. For me, reality has meant striking a compromise between what the zoning laws, neighbors, and my budget would permit, and the performance I would like to have.

Actually, during the first few months after moving to New Hampshire, I did quite well with a variety of dipoles and random wires. But I knew that if I was going to be able to take advantage of improving conditions on 10, 15, and 20 meters, I'd need beams and a good tower to hold them. I also needed a tower to be able to properly evaluate occasional antennas and other items for *73*'s New Products column.

Surveying my present location, I concluded that I could probably maintain a reasonable state of peace with my neighbors and still attain a useful degree of performance with a tower in the 40- to 60-foot range. Another requirement would be that the tower be as inconspicuous as possible. The tower should be of the telescoping, tiltover type, so that work on it or the rotor and antenna could be done from the ground. It should also be fully self-supporting.

After looking over various manufacturers' ads and literature, I decided that the Tele-Tow'r Breakover Model 55 would definitely bear further investigation. A careful study of the literature and a phone conversation with one of the owners of Tele-Tow'r convinced me that the Breakover Model 55 was just what I was looking for. And if I had any lingering doubts, they were dispelled at my first sight of the tower as it was being unloaded from the freight truck.

The Breakover Model 55 may be quite unprepossessing in appearance, especially at first glance, but behind its slim, clean lines lie lots of engineering skill and design innovations—as well as quality materials and workmanship. One of the most attractive things about the tower is that it comes truly complete and ready to install—nothing else is needed.

Tele-Tow'r does offer one accessory item that, while not required for a complete tower installation, can be mighty convenient—particularly if there's a possibility you may want to move your tower at some future date. The item is a tubular steel sleeve into which the tower's base, or breakover riser section, can be slipped instead of setting it directly in concrete. By using the mounting sleeve, you can simply lift the riser section out and carry it away to another location. Otherwise, you're stuck with the choice of digging it out of a 2' x 2' x 3' block of concrete or of leaving it behind and buying a new section.

Try lifting the riser section or the telescoping main part of the tower and you'll instantly gain an appreciation of the solid, rugged construction of the Breakover Model 55. The main part of the tower weighs 300 pounds and is made of three different-sized sections of steel pipe and tubing. The largest section is steel pipe with an outside diameter of 4 inches and .234-inch wall thickness. Next comes a section of steel tubing with an outside diagonal measurement of 2½ inches and a wall thickness of .188 inches. The third section is 10-gauge steel tubing with a 2-inch outside diameter. The winches, the 3/16-inch aircraft control cables, and other fittings are all of excellent quality and workmanship, and are capable of providing years of troublefree service.

The toughest and most time-consuming part of installing the Breakover Model 55 was digging the hole and pouring the concrete for the base. In my own case, I quickly discovered why New Hampshire is called the Granite State. Everywhere I attempted to dig in the area I had chosen for the tower, I ran into stones and small boulders. Eventually I got the job done, but I came away with some beautiful blisters from swinging a pick for the better part of an hour.

Once the hole was dug, things proceeded very smoothly. I had decided to use the accessory mounting sleeve, so it was slipped onto the breakover riser base section and the assembly was placed in the hole. After pouring the concrete, I used a carpenter's level to check that the riser section was level, and left it for a couple of days while

The model 820 portable digital capacitance meter from B&K Precision.

the concrete set.

With the breakover riser section in place and the concrete set, completion of the installation took 15 minutes or less. The first step was to position the tower with winch downward and base against the riser section. The tower was then secured to the riser with a ¾ x 6-inch bolt and nut. Next, the pulley was removed from its housing near the bottom of the tower, the winch on the riser section was released, and the cable was looped over the pulley. The pulley was then reinstalled in its housing and the pulley shaft bolt tightened securely. The tower was then cranked into the upright position and a 3/8-inch U-bolt was installed just below the level of the winch on the riser section, securing the tower to the base.

Fully extended, and without an antenna, the Breakover Model 55 looks more like a flagpole than an antenna tower, something that can be a tremendous asset in a residential neighborhood. The towers come with a silver finish, but you can easily paint them another color or colors to help them blend more effectively with their surroundings, something quite a few owners are apparently choosing to do. In my own case, I think I'll paint the bottom section green, to blend with nearby evergreens, and make the upper portion sky blue.

The Breakover Model 55 is designed to withstand 60 mph winds with 50 pounds of rotor and antenna with a vertical area of 6 square feet when fully extended to 55 feet. With the same loading, the tower will withstand 70 mph winds when cranked down to 45 feet. And, of course, for added safety in high winds or icy conditions or simply when it is not in use, the tower can be cranked down to 23 feet. If you wish, coax and rotor cables can be run inside the tower. Just drill an appropriate-sized hole and feed the cables through, making sure they retract and extend with the tower.

The tower's designers have incorporated a number of interesting and innovative features, including the patented guiding and cable systems and safety stop. The use of round to square to round steel pipe and tubing also contributes to greater ease and safety of operation. While several of the tower's most interesting and important features are internal and of a proprietary nature, thus precluding any detailed description, they clearly help to make the Breakover Model 55 a product of superior quality and performance. I'm mighty glad I chose one for my personal use.

Tele-Tow'r makes four different models. The Breakover Model 55 (extends from 23 to 55 feet) and the Breakover Model 40 (extends from 23 to 40 feet) are telescoping, break over at ground level, and are fully self-supporting. The Model 55 (extends from 21 to 55 feet) and Model 40 (extends from 21 to 40 feet) are telescoping and fully self-supporting. Prices are $618.46 for the Breakover Model 55 and $411.80 for the Breakover Model 40. The Model 55 sells for $442.97 and the Model 40 goes for $242.15. The accessory sleeve is $35.10 for the 40-foot models and $45.90 for the 55-foot models.

The towers and accessory sleeves are available from selected dealers or direct from *Tele-Tow'r Mfg. Co., PO Box 3412, Enid OK 73701, (405)-233-4412.* Reader Service number T52.

LOW-COST PORTABLE DIGITAL CAPACITANCE METER ANNOUNCED BY DYNASCAN

Dynascan Corporation has just announced the introduction of the B&K Precision model 820 portable digital capacitance meter. The 820 is a compact instrument capable of measurement over the wide capacitance range of 0.1 pF to 1 farad. Accuracy is said to greatly exceed the tolerance of most capacitors. The unit features a bright 4-digit LED display for easy reading in laboratories, product lines, or field applications.

The capacitance of virtually any capacitor can be measured quickly and accurately with the 820. Because the accuracy of this unit greatly exceeds the tolerance requirements of most users, required values can be "hand-selected." Matched capacitors can also be singled out for use in bridge circuits and other critical applications.

The 820 allows quick measurement of unmarked capacitors or verification that a capacitor is within tolerance. Virtually any type of capacitor can be measured, from miniature disks to pole-mounted power types. Even the small amounts of capacitance encountered in cable or switches can be measured.

For production line applications, the 820 is an excellent means of pretesting critical capacitors or accurately adjusting trimmer capacitors. The simplicity of operation allows even untrained workers to be quickly instructed in proper operation. To facilitate fast incoming component sorting and selection, slot-type front panel lead-insertion jacks are used. The slot jacks eliminate the time-wasting step of guiding a capacitor lead into the type of small lead-insertion holes commonly found on other instruments.

In classroom applications, the 820 can be used to verify capacitor network calculations by measuring the actual value of a network. The operation of a variable capacitor can also be demonstrated, as can the effects of heat or cold on a capacitor.

The B&K Precision model 820 comes with a 26-page detailed manual. Optional accessories include the BP-28 rechargeable battery pack, the BC-28 charger, and the LC-28 carrying case. The 820 is now available for immediate delivery at local B&K Precision distributors. For additional information, contact *B&K Precision, Sales Department, 6460 West Cortland Street, Chicago IL 60635, (312)-889-9087.* Reader Service number B45.

HAMTRONICS' VHF LINEAR AMPLIFIERS

One of the best and least expensive ways I know of getting started on VHF/UHF, or of expanding your capabilities if you're already active on those frequencies, is with the growing line of Hamtronics kits. Two of the more recent kits are the model LPA 2-45 and LPA 8-45 two-meter linear power amplifiers. The LPA 2-45 is designed to amplify the 2 Watts PEP output of the Hamtronics XV2 Transmitting Converter or the T50 FM Exciter or any other 2-Watt two-meter rf power source to 45 Watts PEP. As a linear, it may be used on any mode, including SSB, CW, AM, and FM. The LPA 8-45 is designed to boost the 8-10 Watt output of the popular two-meter multimode transceivers or other rigs in that power range to 45 Watts PEP. Both models use the same circuitry, with the exception that the first two stages are omitted in the LPA 8-45. Input and output impedance is 50 Ohms. Power requirement is 13.6 V dc at 8 to 10 Amps. The amplifiers may be tuned to any frequency in the 140 to 175 MHz range, and have a passband of 2 MHz.

One of the first things you notice when unpacking the kit is that the power transistors and PC board have been preassembled for you so that the proper spacing, heat-sink compound application, and transistor stud torque are taken care of for you. It's a nice touch and makes the project go more quickly and easily. The transistors are the latest, emitter-ballasted, high-gain types, and are operated well below their full output capability to remain in the linear range. Impedance matching is done with high Q, discrete coil-capacitor-tuned circuits to aid signal purity.

Construction is simple and straightforward. Although the instructions are not of the detailed step-by-step type, they are more than adequate for anyone who has done a bit of home brewing or kit building and who reads them over carefully a couple of times before starting. In fact, building the LPA 8-45 is very much like working from a well-written magazine construction article. Coil winding and special parts mounting procedures are fully detailed, and even I got through the process without any problems or delays. Either model makes an easy and enjoyable afternoon or evening project.

Alignment is very simple. Just connect the input to a two-meter rf source of the appropriate power rating. Connect a VTVM or VOM to the test point pad on the PC board and

The Message Memory Keyer from Trac.

apply moderate drive and B+. Then tune the six trimmer capacitors alternately for maximum output. Continue increasing the drive slightly and repeaking the capacitors until maximum output is achieved (about 10 Amps maximum current drain). Of course, during normal operation you would not drive the amplifier to its limit. However, for alignment, you want to tune for absolute maximum output to establish the proper load for the PA transistors for best linearity on SSB.

The amplifier has an rf output meter detector circuit that may, if desired, be used as an aid during normal operation. A VTVM or VOM, or even a sensitive panel microammeter, may be used to monitor output. An ammeter in the B+ line is another handy operating indicator.

T/R switching of the antenna is not provided for. If a single antenna is to be used with the amplifier and a receiver, some form of coax relay or other method of switching suitable for use in the 144-MHz range must be provided.

Current drain of the amplifier at full output is 8 Amps for the LPA 8-45. If the unit is used in a mobile application, or powered by anything other than a well-regulated and protected power supply, an outboard filter is recommended for hash and transient filtering and reverse polarity protection.

If desired, the amplifier may be mounted to a panel with screws in the left- and right-hand edges of the heat sink. It may be mounted with standoffs to clear the components, or a cutout can be made in the rear panel to clear the PC board and the heat sink then mounted flush to the panel. However the unit is mounted, the fins should be in free air to allow for good convection cooling.

The amplifier has not only given a big boost to my two-meter signal, but it's also provided the satisfaction of building a useful piece of equipment without the hassle of having to round up all the individual bits and pieces needed for such a project. And best of all, at $109.95 for the LPA 2-45 and $89.95 for the LPA 8-45, plus $2.00 per kit for postage, they're affordable. Both models are also available for 6 meters. Heavy-duty versions, rated for 100% duty cycle, are $15.00 more. There is also a 15-Watt amplifier for six and two meters and 220 MHz. The standard version, model LPA 2-15, sells for $59.95, and the heavy-duty version is $69.95, plus $2.00 postage per kit.

Hamtronics kits may be ordered by mail or phone. VISA and Mastercharge cards are accepted. A handy pocket-size free catalog describing all of the Hamtronics kits plus a useful selection of hard-to-find components, antennas, etc., is available on request. *Hamtronics, Inc., 65 Moul Road, Hilton NY 14468. (716)-392-9430.* Reader Service number H16.

TRAC MESSAGE MEMORY KEYER

Trac Electronics, Inc., has introduced a new completely CMOS state-of-the-art Message Memory Keyer. Containing all CMOS integrated circuitry, the Message Memory Keyer contains two-message capacity. Each message has expanded 512-bit memory capacity (50 characters, approximately). The keyer can record at any speed and the messages may be replayed at the same or any other speed. A unique repeat function allows the operator to repeat the message played, as in calling CQ. The heart of the Message Memory is a 1024 x 1 bit CMOS random access memory chip. The all-CMOS unit is virtually rf-proof. In addition to the dual message functions, the keyer contains both dot and dash memory keying, iambic keying, 5-50 wpm, speed, volume, tune, tone, and weight controls, as well as a sidetone with speaker. The unit keys both negative and positive keyed rigs. Available direct from *Trac Electronics, Inc., 1106 Rand Building, Buffalo, New York 14203,* or at most dealers throughout the U.S. and Canada. Reader Service number T18.

RADICAL NEW TOTALLY CONCEALED UHF ANTENNA INTRODUCED BY ANTENNA SPECIALISTS

A new UHF communications antenna designed for total concealment yet offering performance comparable to external mobile antennas has been announced by The Antenna Specialists Co., major producer of land mobile antennas and accessories. The new model ASP-1000 covert antenna is similar in design concept to antennas utilized for jet aircraft (A/S is also a major supplier of avionic antennas).

Producing a vertically-polarized radiation pattern, this cavity-backed slot antenna is constructed of rugged reinforced aluminum with an iridite finish. Included is a silver-plated matching network enclosed in a protective cover. Two screwdriver tuning adjustments allow for precise tuning of the antenna to the required operating frequency.

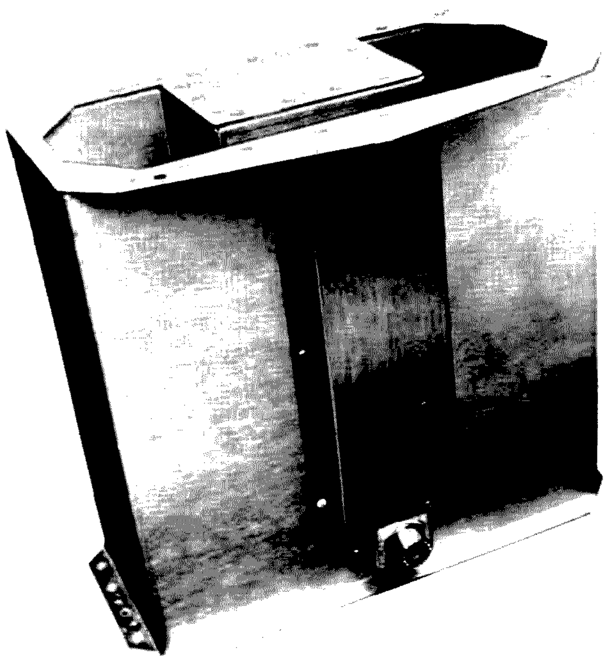
With performance comparable to an antenna mounted externally, the new **ASP-1000** is configured to fit precisely into the space inside an automobile trunk originally designed for mounting a 6" x 9" rear deck speaker. The antenna mounting holes mate with those provided for the speaker and the antenna matches exactly the 6" × 9" oval cutout.

Rf power rating is 125 Watts continuous, bandwidth is 5 MHz minimum, and nominal impedance is 50 Ohms. The ASP-1000 covers the 406 to 512 MHz range. For further information, contact *The Antenna Specialists Co., 12435 Euclid Avenue, Cleveland OH 44106.* Reader Service number A62.

WV-1 WILSON VERTICAL TRAP ANTENNA

No bandswitching is necessary with the new WV-1 antenna. It is an excellent low-cost 10-40 meter vertical that offers an electrical quarter wavelength and a low angle of radiation. Advanced design assures a low swr on each band.

For more information, see your favorite dealer, or contact *Wilson Electronics Corporation, Consumer Products Division, PO Box 19000, Las Vegas NV 89119.* Reader Service number W2.



New concealed UHF antenna from Antenna Specialists.

CONTESTS

from page 8

all DUF countries as per the diploma of the Union F List, 9 Belgian provinces (2 letters), DA2 STN/FBA (Belgian forces in DL), 22 cantons of Switzerland (2 letters), and all other Francophone countries—LX, 40, OD, 3B, 9Q, 9U, 9X, HH, VE2. French stations will give their department number after the call. Example: F6ZZZ/67 and FFA will give DA . . . /FFA. Final score is the sum of the QSO points times the sum of multipliers. Send logs and summary sheet to the REF Traffic Manager, 2, Square Trudaine, 75009 Paris, France.

CLASSIC RADIO EXCHANGE
Starts: 2000 GMT Sunday, January 28
Ends: 0300 GMT Monday, January 29

Sponsored by the Southeast ARC, K8EMY, Cleveland OH, the contest is open to all. Object is to restore, operate, and enjoy older equipment with like-minded hams. A classic radio is any equipment built since 1945 but at least 10 years old, an advantage, but not required in the exchange. Exchange your name, RST, QTH, receiver and transmitter type (home brew send PA tube, i.e., "6L6"), and other interesting pleasantries. The same station may be worked with different equipment combinations, and on each mode on each band. CW call is "CQ CX." Phone call is "CQ EXCHANGE." Non-contestants may be worked for credit. Suggested frequencies: CW—up 60 kHz from low band edges; phone—3910, 7280, 14280, 21380, 28580; Novice/Tech—3720, 7120, 21120, 28120. Listen to 10 meters on the quarter hour, 20 on the half hour, 15 on the three-quarter hour.

SCORING:

Add the numbers of different transmitters, receivers, states/provinces/countries contacted for each band. Multiply by total number of QSOs. Multiply that total by the Classic Multiplier: total years old of all transmitters and receivers used, three QSOs minimum per unit. For transceivers, multiply years old by two.

ENTRIES:

Please send logs, comments, anecdotes, etc., to Stu Stephens K8SJ, 2386 Queenston Road, Cleveland Heights OH 44118. Include an SASE for results and a copy of the *Classic Radio Newsletter*.

MINNESOTA—ST. LOUIS COUNTY AWARD

This award is issued for having contacts with three stations in St. Louis county, Minnesota, with no date, mode, or frequency restrictions. The award is also available to SWLs on a "heard" basis. Do not submit QSL cards; send log information, $1.00, and two 15¢ stamps to: Wilderness Ham Radio Operators, Certificate Manager, Ron Heruth WA0WNV, 321 Wyandotte Rd., Hoyt Lakes MN 55750.

BEATA OPERATION

A Dominican ham radio group affiliated with the Dominican Radio Club is concentrating its efforts on trying to offer its country and the world the possibility of working for the first time the HI1 prefix. Beata Island is a restricted area, a military restricted area under the administration of the Dominican Marine Corps. As of October 19, the activity was scheduled for January 25-28 and the group will include: Waldo HI8WPC, Max HI8MVF, Joe HI8JAG, Mike HI8MRF, Tim HI8MFP, and Carlos HI8XPT.

No stations other than the above-mentioned are authorized to work the HI1 prefix. If any call was made prior to the date of this DXpedition, it would not be valid. A weekly bulletin will be issued until the exact day of the DXpedition, containing interesting information about the island and the operation. Suggestions or information can be requested at: Beata Operation Public Relations, HI8MFP, Box 2191, Santo Domingo, Dominican Republic, West Indies.

THE 73 MAGAZINE 10 METER AWARDS

The return of vigorous solar activity means that 10 meters is once again a band to be reckoned with. Ol' Sol's 11-year cycle of sunspot production is about to hit a peak, with the result that QRP 10 meter DX is possible.

Now's the perfect time to convert that old CB rig to 10. American Crystal Supply makes a variety of simple and inexpensive conversion kits, or you can do-it-yourself from the articles in 73. True appliance operators can purchase ready-made rigs from Bristol Electronics or Standard Communications. To give you an added incentive, 73 is offering two nifty Certificates of Achievement for 10 meter channelized communications.

For domestic types, there is the 10-40 Award. This one should be pretty easy—just work 40 of the 50 states. The DX Decade Award goes to DXers who work 10 or more foreign countries with a channelized 10 meter rig. We have endorsement stickers, too—the whole bit.

To give everyone an equal shot at award #1, only contacts made October 1, 1978, or after will be valid.

Well, don't just sit there. Get out your soldering iron, order some crystals, and put that CB rig on 10. This is going to be fun, so don't miss out!

RULES

1) All contacts must be made in the 10 meter amateur band using channelized AM equipment. Both converted Citizens Band equipment and commercially-produced units may be used.

2) To be eligible for award credit, all contacts must be made October 1, 1978, or after.

3) The 10-40 Award is available to applicants showing proof of contact with stations in at least 40 of the 50 United States. A special endorsement sticker will be available to those working all 50 states.

4) The DX Decade Award is available to applicants showing proof of contact with at least 10 foreign countries. Endorsement stickers will be awarded for 25, 50, 75, and 100 countries.

5) A log of stations worked, with the date, time, and type of equipment used for each contact, must be submitted when applying for each award or endorsement.

6) Each application for an award or endorsement must be accompanied by a signed statement that all claimed contacts are valid. No QSL cards need be sent, but they must be in the possession of the applicant.

7) To cover costs, a fee of $5.00 must accompany each application for the 10-40 or DX Decade Award. The fee for endorsement stickers will be $2.00 each.

8) All award applications should be mailed to: Chuck Stuart N5KC, 5115 Menefee Drive, Dallas TX 75227.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

ATLANTA IN JUNE

Dayton is still the largest hamfest in the country, but Atlanta is undoubtedly the second largest—and closing in on Dayton. Atlanta has two major pluses and one minor plus which Dayton doesn't have. The biggest plus is the city of Atlanta, with its incredible variety of entertainment and restaurants. That in itself is worth the visit. The second big plus is the masterful planning and enthusiasm of Chaz Cone W4GKF, the magician who has put this show together.

Chaz, with the help of cochairman Bob Verlander W4BCD, has organized a fast-paced and well-run show. They get the best in exhibits and somehow manage to bring in standing-room-only crowds for the forums. Perhaps it is the number and quality of the prizes that are responsible for keeping the place packed, even on Sunday. This is the *only* hamfest I've ever seen where it is even more packed on Sunday than on Saturday.

The minor plus, at least to some of us, is that I have an opportunity to speak in Atlanta . . . which I don't at Dayton. Last year at Atlanta, I held one session on current events in amateur radio and another on current events in microcomputing. I expect I'll be doing the same this year.

My ham session might be a good place for ARRL cultists to come to discover what many amateurs already know . . . that I don't hate the ARRL. It may be time to bring this out in the open and talk about it. You know, it's funny about that . . . when I'm critical of the FCC, everyone nods in agreement, and I don't hear any cries of anguish about me being anti-FCC. When I'm critical of our government, I don't get anything but agreement. When I'm critical of the League, then I'm "slamming" them. Baloney. Why should the League be a sacred cow, with people having apoplexy at criticism? Is the ARRL a religion? Let's put these things into perspective and not let a cult mind rule out intelligent discussion of ham events.

Sure, I suppose I should be more political and not so direct. If you don't offend anyone, you have no enemies . . . but neither have you any share in the satisfaction of helping to improve the world a notch. When I see something wrong, I speak out and try to do something about it, a trait which makes politicians nervous. I speak out about the government, about the FCC, the ARRL, civil defense, and anything else where I see things going wrong. Yes, and I expect to get stoned for my trouble . . . though I don't enjoy it. Can you name one person who has spoken out who didn't make people angry?

One of the things I believe in is amateur radio. I believe that our hobby is one of the reasons why the United States is so outstanding in electronics and communications. Over a million of the people in this country have been hams at one time or another, and this personal spark of self-interest sets them aside from the strictly professional technician or engineer. A ham will usually go that extra distance to get something done, while the "professional" knocks off at 5:00 pm to go home and watch television.

Amateur radio has changed the lives of these million kids . . . and the course of events for our country. Just look at the amazing correlation between the development of foreign countries and the number of their hams listed in the *Callbook* . . . do you really think that is a coincidence? We all know that hams discovered and pioneered most of the presently-used radio techniques . . . and would have worked out a lot more if they hadn't had the FCC fighting them at every turn for years.

Whether amateur radio means rag chewing, building special projects, civil defense, emergency nets, contests, DXing, repeaters . . . whatever it means, I feel that amateurs are part of a special breed which is very important to the world. Before you put down the jerk who sits there clunking the repeater, remember that with the right motivation this fellow may suddenly get into some special interest in amateur radio and pioneer a whole new mode of communications. I try to provide as much of this spark as I can with the articles in *73*.

When I hear or read that I'm trying to tear down amateur radio, I wonder who could possibly believe such bunk. I've built most of my life around amateur radio for the last 25 years . . . and that *is* most of my life. I've made it my business to keep up with just about everything going on and the people involved. I've participated with enthusiasm in just about every phase of the hobby, starting out back in the 1930s with CW on 40m and 2½m VHF work. I've been into DXing, DXpeditioning, contests, RTTY, SSB, and SSTV, got into FM and repeaters in the 60s with my own repeater, and have a reasonable score via OSCAR in mode B (the hard one). No, I'm not about to tear down amateur radio.

Come to Atlanta, and let's get together to see if we all aren't

LETTERS

JONESTOWN

We believe that radio broadcasts were made from Guyana to San Francisco on the day before and the day that Congressman Leo Ryan was killed in Guyana.

Our office would appreciate your magazine printing a request for any ham radio operator who had contact with the People's Temple radio on November 17 and/or November 18, 1978, to contact the San Francisco District Attorney's Office at either (415)-553-1505 or (415)-553-1054 (call collect).

Thank you for your service.

District Attorney's Office
San Francisco CA

AMMUNITION

As I was stuffing my husband's numerous magazines in the usual 99% of the closet (headache of wives of all hobbyists), I happened to drop your Aug., '77 issue of *Kilobaud*. It fell open to an article entitled, "Sooo, You Want To Be An Author." With nothing else to read in the house but medicine bottles and vegetable cans, I read it. I cannot possibly tell you of my utter amazement at having my husband so perfectly described. The excuses used by your aspiring authors(?) were classic—he's used every one of them, several times, in fact.

Believe me when I say that I am sick and tired of being used as a sounding board for ideas, criticisms, and comments perpetrated by your magazines (he's an avid *73/Kilobaud* reader). My question is this: Why discuss these subjects with a totally unwilling victim when there are people out there who would be happy to hear them? You must realize that I haven't the faintest idea what he's talking about.

I have tried tactful suggestions like "Why don't you get off your backside and write down your ideas and send them in?" Well, the answer, of course, is obvious. Just look at the list given in that article.

I finally drew the line when an article appeared in your magazine this month. The author had the same ideas that my husband had four months ago. And you paid the man one hundred dollars for it.

Just this month, my husband was wishing that there was some way he could buy the computer he wanted so he could start sending in programs (he's a computer technician working for his BSEE). He has the knowledge and the intelligence, but he has no confidence in himself. So, like the dutiful and loving wife that I am, I exercised my right to nag him until he actually sat down and started to write. It's been two days since he started and it's almost finished. Though I am by far no expert, I think it's great.

So, Mr. Green, thank you for supplying the ammunition that was needed for a short but productive battle.

Be looking for a superb article written by a very proud WB0FGO.

Jean M. Johnson
Sioux City IA

WRONGLY POINTED?

I am an avid reader of *73 Magazine* and appreciate your many disclosures of vendors who do not live up to their claims. I do feel it my duty, however, to advise you when it appears the finger has been wrongly pointed. Reference the letter entitled "Skin Disease" on page 118 of the October issue: I sympathize strongly with Mr. Carver about his treatment from Kensco Communications. His accusations towards Southeastern Communications, while certainly understandable, are not warranted, however.

I have dealt with this firm three times in the last six months, each time with excellent service. Actually, this firm seems to go out of its way to please. Upon receipt of the first order of six crystals, which arrived one week after order, one crystal was bad (no one's perfect). It was mailed back on Thursday, and its replacement arrived the following Wednesday. The second order was back-ordered and then shipped special delivery at Southeastern's expense when they were advised of the urgent need. The third was requested on a Thursday evening by phone and arrived the following Tuesday.

I don't know what more to say. Hopefully, it will not be long before service such as this is recognized. It seems unfair that a company should acquire the reputation of another just because they buy their stock.

Thanks for the chance to put in a good word for a good company. I hope you'll print this so others can see both sides of the story.

Keep up the good work, Wayne. You certainly help make an already interesting hobby more interesting.

Joe Bushel N4ARJ
Orange Park FL

SEEING THE LIGHT

After years of putting down "Chicken Banders," the light suddenly dawned that I might be missing something. My unfair speeding ticket for 50 mph in a country "30 mph zone" was the final clincher. I couldn't help but notice, as the polite but firm officer was writing my summons, that all cars with CB antennas were leisurely proceeding through the speed trap at a mere 29 mph.

I muttered all the way home: "I just gotta get me a CB." My XYL only shook her head—she's used to my muttering.

A short time later, while wandering through a local hamfest flea market, I encountered an enterprising CB dealer who was selling new (outlawed) 23-channel CB radios, sans mike, as "CB monitors" for only $7.00 each. He assured me that there was no transmitter in the case, only the receiver. Hmm—perhaps he was "mistaken" about the "missing transmitter." My sporting blood said "buy," but my intuition does not always give me the best advice. For instance, the bumper sticker on my Edsel used to say "AM—YES, SSB—NO." You get the drift!

So I bought the $7.00 wonder and after further searching and dickering bought a microphone for $1.00 and a used Hustler mobile CB antenna for $2.00.

Not wanting to wait until I arrived home to test the rig, I nervously connected power leads to fuse block and ground, plugged in the dollar mike, temporarily connected my 5/8-wave 2 meter FM antenna, and turned on the switch. Immediately my car was filled with rasping, squawking CB signals! At least the receiver section worked. Now for the acid test. I turned the channel selector to a relatively quiet channel, squeezed the push-to-talk switch, and timidly requested a signal report. "Wall to wall and treetop tall" came back the report from a mobile station claiming to be eight miles from my location! Success! I had achieved "Good Buddy" status for only $10.00. Could have had it for only $8.00, if I hadn't bought the antenna! Say, wonder if the guy who sold me the $2.00 Hustler will take it back at next year's Syracuse Hamfest?

Palmyra NY

GOOD-BYE

I have received a notice that it is time to renew my long-standing subscription to *73 Magazine*. I have decided not to renew. Among the reasons for this decision, the following are the most pertinent.

The editorial policy of your magazine appears to promote unlawful activities and to encourage your readers to be scofflaws. I refer especially to your articles about radar jamming. Amateur radio does not need a spokesman who advocates this type of activity, and I certainly do not care to support the distribution of this type of material. Your proposal for the formation of a religious cult to further impede enforcement of the law borders on the ridiculous.

It would seem to me that if you would devote your talents to the enrichment of amateur radio instead of filling your editorial columns with attacks on the ARRL and the FCC, your magazine would benefit. One cannot build a desirable reputation by degrading others!

Your conduct is hurting not only amateur radio, but also your pocketbook, which, if I read between the lines correctly, is very near to your heart! It is my understanding that many others feel as I do and are not renewing their subscriptions. I was a charter subscriber to both *Byte* and *Kilobaud*, and when my *Kilobaud* subscription expires, it will not be renewed.

Mel Hart W0RV
St. Louis MO

MORE ON KM1CC

I was glad to read the article, "The KM1CC Story," in the October issue of *73 Magazine*. However, I should correct the statement made about the equipment loaned to KM1CC by RCA Global Communications, Inc. The reference to "a modern WCC inked-paper readout receiver" isn't quite correct.

First, the inked-paper re-

ceiver, more appropriately recorder, isn't a receiver as most of us would think of a receiver. Typically, when we speak of receivers in the amateur radio vernacular, we are talking about devices used to detect radio signals and convert them to a form of audio signal. The above-mentioned recorder does not detect radio signals; rather, it uses audio to control the deflection of a stylus, thus yielding an inked trace of the input audio.

Neither would I describe the equipment as *modern*, because it dates back before World War II and hasn't been used at WCC since about that time. Incidentally, the receiver loaned with the recorder was an old Radiomarine AR-67, an LF and MF band receiver used at WCC quite a few years ago and hardly modern.

The equipment loaned by WCC was to enable the non-amateur to observe a visual display of CW signals. In this case, the recorder and the AR-67 receiver were used to monitor the WCC 500 kHz, A-2, CW signal.

I felt these points should be brought out so that the astute reader doesn't get the impression that we (WCC) are still using the *old* inked-paper recorder and calling it *modern*.

PAINT RIP-OFF

This note is to notify your readers of a new rip-off. It's called "Paint falling off your car due to rf." This BS is being passed around to auto dealerships and auto paint shops—that rf makes paint fall off cars in the area of the antenna. In my case, my new '78 car's trunk lid is discolored and the paint is chipping off. The dealer says that my radios are making it do that and that they are not going to fix it. I have talked to several other radio ops and they were told the same thing about the paint on their cars.

If this happens to anyone else, call the local Consumer Affairs Office and raise hell. I did, and it worked.

Jacksonville FL

CODE SUCCESS

Your long-standing theory on teaching Morse characters at high speed while spacing them out to make 5 wpm is working out well for a class of prospective Novices I'm teaching. I explained that I was doing this in order to have them learn letter sounds instead of having them go through the double step of counting dots and dashes and then translating that to letters. They accepted the logic of this and seem to be having no trouble copying letters at 15 wpm, spaced to about 7.

Linc Thorner WDØCLB
Minot AFB ND

TOMBSTONE GAMBLING

"New Life for Old Transformers" in the January, 1978, issue was excellent, but one cringes when instructed to connect 110 volts to "what you suspect are the primary leads"! Gamble wrong and the author's address of Tombstone could become sadly appropriate.

A safe and constructive suggestion is offered: First, set the ac voltmeter to its highest range. Energize a separate 6.3-volt transformer and apply its low voltage to the unknown windings. When approximately 110 volts is measured across another winding, *that* is the primary, and the energized winding is a 6.3-volt winding. *Now* it is safe to apply 110 V ac to the primary and identify any remaining windings.

Gene Brizendine W4ATE
Hunstville AL

BOX-BUSTER

Well, Wayne, you have done it again!! Here I am looking at my nice new set of library shelf boxes and wondering how the heck I am going to get the December Issue of *73* into one of them which already contains the first eleven issues! Leave it to Green to sell you a product and then have such a thick set of magazines that you can't possibly fit a whole year's worth of mags into it. I didn't have any problem fitting in some of the other mags! Oh well, I guess I'll just have to put the December issue alongside the box when I get it! Keep up the good work, and keep those RTTY articles coming.

Robert J. Farrell Jr. WB2COY
Poughkeepsie NY

THE WORD FROM JEDDAH

My friend W9MXU receives current copies of *73 Magazine* here in Jeddah (costs $5.05 US to mail the copies to him each month). I would say you have a devoted subscriber indeed!!

What is great is that he shares *73* with me and now I want to be a subscriber—enclosed is my subscription for 3 years. Please send *73* to my home QTH in the USA.

There are many hams here in Jeddah from all over the world, as well as many from the U.S.A.—all we can do is listen to all those beautiful CQs on all the ham bands! I'm using a portable Toshiba RP-2000F receiver covering FM broadcast through 30 MHz; it also has a bfo for SSB and CW. It's a fine little receiver and I had not seen it in the U.S.A. before leaving for Arabia.

I hope when I arrive home I will have my first issue of *73*—that would be great. The very best to you and your organization on the outstanding job you do for amateur radio.

David O. Finnell W5LCL
Jeddah, Saudi Arabia

COMMON SENSE

My hat is off to Wayne Green and his magazine as the finest amateur radio publication on the market. Contrary to Merrill Eidson's comments that Wayne should stop attacking the ARRL and stick to improving *73*, I feel that Wayne is justified in his comments on the ARRL.

Merrill mentioned being a solid member of the ARRL for fifty years in his letter. This is indicative of quite a few members of the organization. Most are from the spark-gap era and the big guns running the organization operate it with this antiquated style.

I have been a ham for a number of years and feel that a magazine such as *73* is progressive and certainly represents the modern technology and operating practices of amateur radio. The only value I ever received from *QST* was who made DXCC, WAS, etc. As for technical articles of value, *QST* never did impress me.

The ARRL certainly needs to work more for the interests of all hams instead of trying to promote measures that will benefit the elite group. A more down-to-earth approach by the ARRL would restore my faith in the organization.

Wayne, keep up the good work. You have my full support. Your common-sense approach to amateur radio is needed to keep things in their perspective.

Dick Sullivan KØDQG
Des Moines IA

PETTING

Thanks to Paul A. Lilie for his fine article on the Commodore PET ("Look What Followed Me Home!", page 142, November, 1978). One of his "complaints" regarding the tape-handling system is the difficulty he experienced finding the end of program B on a tape when he wants to load a new program, A, on the same tape (he listens on an audio cassette deck for the end of the noise).

I have a better suggestion: Ask PET to VERIFY "B". PET will search for B, find it, compare it with A in memory and report a "VERIFY ERROR." No matter, you've found the *end* of B, which is what you need before asking PET to save "A". PET stops at the end of the VERIFY process.

The PET's implementation of the IEEE-488 bus makes it a truly professional machine, well beyond the mere "hobby video game" class.

How about some articles on the use of PET as a Morse/RTTY terminal?

Ham Help

We would like to swap club newsletters with other amateur radio clubs. If interested, contact:

Sterling-Rock Falls Amateur Radio Society
c/o Donald Van Sant WA9PBS
1104 5th Ave.
Rock Falls IL 61071

In the last few years, I have been looking for a list of the frequency bands and power limitations of amateur stations in foreign countries. It is my opinion that such data would prove valuable to many amateurs, both foreign and domestic. Most of the information on the American amateur bands is widely published and well-known, but that of many foreign countries is believed to be considerably restricted. Help in directing me to a source of this type of information would certainly be appreciated. Thanks for any information anyone may be able to provide.

Paul Wiegert W8TH
1205 East Franklin St.
Centerville OH 45459

I would appreciate (and pay reasonable expenses, if necessary) info on solid-stating (ICs?) a WWII-type BC-221-m frequency meter. If I build modular, why can't I use it for CW vfo? All responses acknowledged. Thanks.

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

THE WEST AUSTRALIAN 150TH YEAR CELEBRATION CONTEST

The aim of the contest is for amateurs on all continents to contact amateurs in Western Australia (VK6) on all bands using all modes, this being to commemorate the 150th year celebration of the foundation of Western Australia.

The contest will commence at 1600Z on 31 December, 1978, and end at 1600Z on 31 December, 1979.

All authorized amateur bands may be used between 1.8 MHz and 28 MHz using any of the modes appropriate to the regulations applying to the entrant. Operators are encouraged to operate both phone and CW.

The three highest scores from each continent for mixed and individual modes will receive a commemoration certificate. This contest is also open to SWLs.

For VK amateurs and SWLs, the three highest scores from each state will be eligible for a certificate, while VK6 participants who have more than 100 out-of-state QSOs will get an award.

SCORING:

One contact in each mode is allowed in each band every day with the same station, for which the following scores and multipliers will apply: CW—5 points per contact; phone—3 points per contact; RTTY—6 points per contact. Multipliers: One point per band used, provided that 30 QSOs are obtained on that band, except for 1.8 and 3.5 MHz, where 1 QSO will count. Final score = total points × total multipliers.

LOGS:

Contest logs should show date, time, call, band, mode, RST out, RST in, points scored, and include a running total. The log should bear a front cover sheet bearing the following: call, address, claimed score, and signature. Contest logs are to be forwarded to: The Contest Manager, 150th Celebration Contest, PO Box 6250, Hay Street East, Perth 6000, Western Australia.

NEW HAMPSHIRE QSO PARTY
2000 GMT February 3 to 0500 GMT February 4
1400 GMT February 4 to 0200 GMT February 5

The contest is sponsored by the Concord Brasspounders, Inc., W1OC, to promote the Worked New Hampshire Award. Stations may be worked once per band per mode. NH stations may work each other.

EXCHANGE:

NH stations send RS(T) and county, others send RS(T) and ARRL section or country.

SCORING:

NH stations score 1 point per QSO times the number of ARRL sections plus countries plus NH counties. Others score 5 points per NH QSO times the number of NH counties.

FREQUENCIES:

CW—1810, 3555, 7055, 14055, 21055, 28130; Phone—1820, 3975, 7235, 14280, 21380, 28575; Novice—3730, 7130, 21130, 28130; VHF—50.115, 145.015, FM simplex (no repeaters!).

AWARDS:

Top scorer in each NH county and top scorer in each state, province, and country (50 points min.). Additional certificates available for confirmation of all 10 NH counties. Send logs, summary, and checksheets to: Concord Brasspounders, Inc., C. Halloway, 9 Via Tranquilla, Concord NH 03301. Mailing deadline is March 12. Include a business size SASE for results and/or award.

TEN-TEN INTERNATIONAL NET WINTER QSO PARTY
0000 TO 2400 GMT on February 4 and February 11

The contest is open to all amateurs, but only members are eligible for awards. All contacts must be made on 10 meters. Classes of operation include: single-op, multi-op, and QRP (20 Watts PEP or less). A station may be counted only once; all logs must be in GMT. Stations with new calls must list old callsign. All QRP stations must list equipment used.

THE 73 MAGAZINE 10 METER AWARDS

The return of vigorous solar activity means that 10 meters is once again a band to be reckoned with. Ol' Sol's 11-year cycle of sunspot production is about to hit a peak, with the result that QRP 10 meter DX is possible.

Now's the perfect time to convert that old CB rig to 10. American Crystal Supply makes a variety of simple and inexpensive conversion kits, or you can do-it-yourself from the articles in 73. True appliance operators can purchase ready-made rigs from Bristol Electronics or Standard Communications. To give you an added incentive, 73 is offering two nifty Certificates of Achievement for 10 meter channelized communications.

For domestic types, there is the 10-40 Award. This one should be pretty easy—just work 40 of the 50 states. The DX Decade Award goes to DXers who work 10 or more foreign countries with a channelized 10 meter rig. We have endorsement stickers, too—the whole bit.

To give everyone an equal shot at award #1, only contacts made October 1, 1978, or after will be valid.

Well, don't just sit there. Get out your soldering iron, order some crystals, and put that CB rig on 10. This is going to be fun, so don't miss out!

RULES

1) All contacts must be made in the 10 meter amateur band using channelized AM equipment. Both converted Citizens Band equipment and commercially-produced units may be used.

2) To be eligible for award credit, all contacts must be made October 1, 1978, or after.

3) The 10-40 Award is available to applicants showing proof of contact with stations in at least 40 of the 50 United States. A special endorsement sticker will be available to those working all 50 states.

4) The DX Decade Award is available to applicants showing proof of contact with at least 10 foreign countries. Endorsement stickers will be awarded for 25, 50, 75, and 100 countries.

5) A log of stations worked, with the date, time, and type of equipment used for each contact, must be submitted when applying for each award or endorsement.

6) Each application for an award or endorsement must be accompanied by a signed statement that all claimed contacts are valid. No QSL cards need be sent, but they must be in the possession of the applicant.

7) To cover costs, a fee of $5.00 must accompany each application for the 10-40 or DX Decade Award. The fee for endorsement stickers will be $2.00 each.

8) All award applications should be mailed to: Chuck Stuart N5KC, 5115 Menefee Drive, Dallas TX 75227.

* = described in last issue.

Stations can credit any chapter with their score as long as they hold a certificate from that chapter.

EXCHANGE:

Call, 10X number, ARRL section, and name.

SCORING:

Continental USA contacts are 1 point, 2 points if 10X member. DX (outside continental USA) are 2 points or 3 points if 10X member. QRP contacts are 2 points or 4 points if 10X member.

ENTRIES:

Members only send logs to Robert C. Mugherini WA1AKS, PO Box 169, Randolph MA 02368. Logs must be received no later than March 11. Results will be published in the 10-10 Net spring bulletin.

AWARDS:

For each class, 1st place certificate to each US district, KL7, KH6, and other US Pacific Islands; each VE district, Central America, and Caribbean; So. America; Europe; Africa; and So. Atlantic, Asia, Australia, New Zealand, and So. Pacific.

QCWA MEMBERSHIP QSO CONTEST

CW:
0001 GMT Saturday, February 10 to 2400 GMT Sunday, February 11
Phone:
0001 GMT Saturday, March 10 to 2400 GMT, Sunday, March 11

Historically, the QCWA membership contest has been held on a single weekend for both modes of operation. For greater participation in 1979, the contest will be held on two weekends separated by one month. For additional interest and point-scoring purposes, three global areas have been established. Frequencies, confirmation texts, and related contest rules and guidelines are available in the *QCWA News.*

TWO-LAND QSO PARTY

2100 GMT Saturday, February 17 to 0700 GMT Sunday, February 18
1300 GMT Sunday, February 18 to 0300 GMT Monday, February 19

This is a new contest organized by the South Jersey Contest Coalition. There is no operating time limit within the contest periods, but there is a mandatory 6-hour rest period from 0700 to 1300 on Sunday. The same station may be worked once per band and mode, and mobiles and portables may be worked each time they change counties. The states of New Jersey and New York, with 83 counties, will try to work the world and vice versa!

EXCHANGE:

RS(T), county, and state for Two-Land stations. RS(T) and state, province, or country for others.

FREQUENCIES:

CW—1805, 3560, 7060, 21060, 28060; SSB—1815, 3900, 7230, 14280, 21355, 28600; Novice—3725, 7125, 21125, 28125.

SCORING:

Each QSO counts 2 points. For Two-Land stations, the multiplier is the number of states, provinces, and DX countries (by DXCC) plus the number of Two-Land counties. For all others, the multiplier is only the number of Two-Land counties (83 max.).

AWARDS:

Certificates to the top scoring station in each Two-Land county, each state, province, and DX country. Second- and third-place awards will be issued where justified. Awards also for top mobile, portable, multi-operator, Novice, and club.

ENTRIES:

Logs with over 200 QSOs should include a dupe sheet. Indicate each new multiplier as worked. Also, include a summary sheet and usual declaration. For results, include a large SASE; DX stations include a large SAE. Send entries to: South Jersey Contest Coalition, c/o AB2E, Darrell Neron, 322 S. Cummings Avenue, Glassboro NJ 08028.

THE UNIVERSITY OF CAPE TOWN FESTIVAL AND AWARD, 1979

To commemorate the 150th anniversary of the University of Cape Town, Cape Town, Republic of South Africa, the Cape Town branch of the SARL will operate a special festival station with call ZS1UCT (ZS1-*U*niversity of *C*ape *T*own) and issue an award.

The University of Cape Town Festival Station will operate Saturday, February 17, to Sunday, March 4, 1979, Saturdays and Sundays 0600 to 2000 GMT, and weekdays 0700 GMT to 1000 GMT, 1500 GMT to 2000 GMT.

FREQUENCIES:

Use for calling. Actual frequency will depend on QRM. 40 meters—7.050 MHz. 20 meters—14.210 MHz. 15 meters—21.200 MHz. 10 meters—28.580 MHz. 2 meters—145.500 MHz.

TRANSMISSION MODES:

SSB, CW, RTTY, and FM.

SARL Bureau, P.O. Box 3037, Cape Town 8000, Republic of South Africa.

RULES AND AWARDS:

The award is open to all licensed amateurs and shortwave listeners (SWLs). DX stations and SWLs must log **ZS1UCT** plus two **(2)** other ZS1 stations (ZS1 contacts to be logged between February 15 and March 15, 1979). ZS and ZR stations log ZS1UCT plus 5

Five-Chip Auto IDer

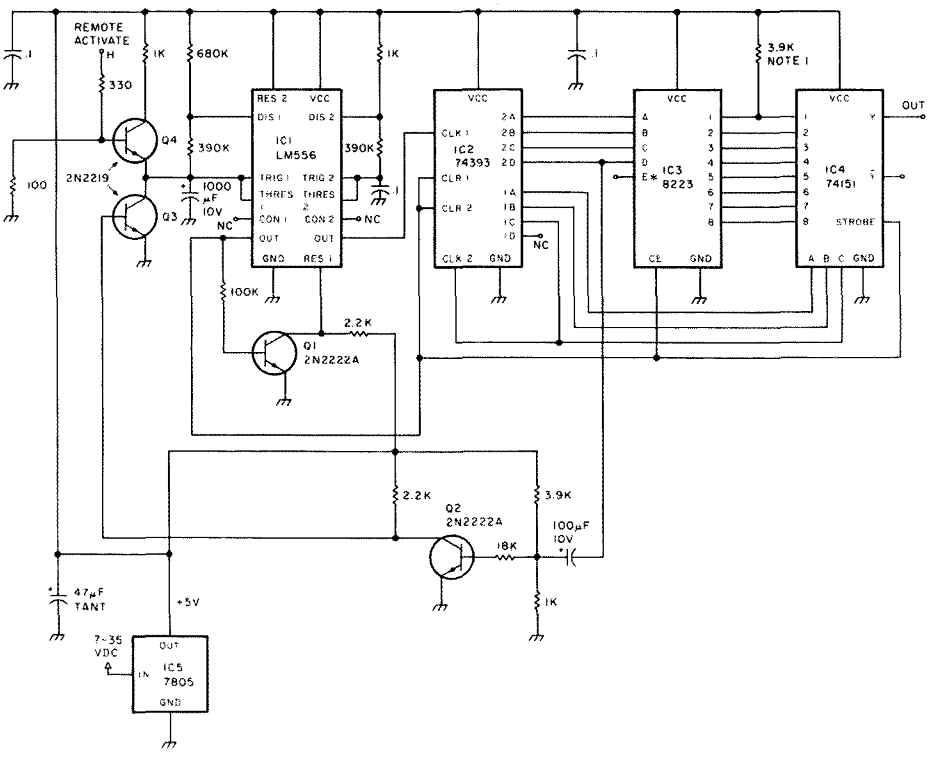
—in case you forget

You don't have to speak TV to use this one.

Richard Bartholomew
Box 300 Butler Terrace
Freeland PA 18224

Having seen several articles pertaining to automatic code identification, all using diode matrices or one-shots, I thought I'd share a circuit I developed for TV translators requiring much the same thing. This particular circuit uses only five ICs, three TTLs (cheap), one 5-volt regulator, and one 256-bit ROM (read only memory). There are also four transistors performing housekeeping chores such as inversion and pulse generation.

Referring to Fig. 1, the circuit operation can be explained as follows: IC1, an LM556 dual timer uses half of its internal circuitry to provide a 30-minute timer. The output of this timer is normally high. After timing-out, it goes low which turns off Q1 and forces the reset pin on the second half of the timer to go high. This enables the astable oscillator, and a clock stream, at about 8 Hz, toggles IC2, a dual 4-bit binary counter. This counter performs two functions. First, it addresses IC4, an 8-line-to-1-line multiplexer, which causes IC4 to selectively scan its inputs for a signal. Going back to IC2 now, it also addresses IC3, a 32 word, 8 bit/word ROM. The output of the first counter also drives the clock input of the second counter at a speed 8 times slower than the first half. This causes the multiplexer to scan each of its 8 inputs before the ROM address changes once.



The ROM is programmed as shown in Table 1. I always allow the first three bits at address 00000 to be 0. This allows for any clearing operations of the counters to com-

*Fig. 1. Schematic diagram of automatic code ID circuit. *Tie high or low depending on*

used the letters "DE W79QY7." I allowed 3 consecutive 1s for a dash and one 1 for a dot. Spacing between letters is three 0s and spacing between words is seven 0s. The table is read from address 00000, A through H, then address 00001, A through H, and continuing down through binary address 01111. As can be seen, the ROM outputs 8 bits at a time to the 8 inputs of the multiplexer. This is the reason for running the multiplexer 8 times faster than the ROM. As each 8 bits appear on the inputs to the multiplexer, the inputs are scanned and converted to serial data at the Y output.

At the completion of binary count 16, the negative-going edge on the 2D output of IC2 turns off Q2 for a period of about 100 ms. This causes its collector to go high. This high voltage on the base of Q3 forces it into heavy saturation, discharging the time-out capacitor at TRIG 2 on IC1. This causes the timer to reset to zero and start timing out 30 minutes, when the sequence will repeat. Q4 was added to allow remote triggering of the timer. This is accomplished by either a logic 1 at the remote activation input or tying this point to +5 volts.

IC5 is simply a 5-volt regulator which takes anywhere from 7 to 35 volts input and converts it to 5 volts for the rest of the circuity.

This circuit can be programmed to provide two separate 128-bit messages, selectable at the flip of a switch. Input E on IC3, which is shown open on the schematic, can be tied to an SPDT switch which has one side grounded and the other tied to +5 volts. When switched to ground, the address to the ROM will start with 00000 and when switched to +5 volts, it will start with 10000.

Being a computer freak and not a ham, I am not sure if this circuit will be an aid to anyone, but if so, I would like to hear from you regarding your uses and any changes you might have made. (For amateur use, the 30-minute timer sequence would have to be shortened to 10 minutes. The sample call sounds like a rare one.—Ed.) ■

The Vacationer

—B&W's portable antenna

Steve Schwartz WA2ALT
2770 West 5 St. Apt. 18A
Brooklyn NY 11224

If you travel a lot or live in an apartment, there's a great little antenna for the low bands. B&W makes a low-band antenna covering 2-40 meters and it virtually takes up no space. The antenna is about 4½ feet long. When the antenna is disassembled, it can fit in a small suitcase with all your clothes. This antenna is the Vacationer™.

The antenna comes with four coils and a shorting bar for 6 and 2 meters. The Vacationer also comes with coax, counterpoise, and all mounting hardware.

Changing coils is a breeze. To change a coil, all you have to do is loosen two screws and the coil slides right off. Tuning the antenna is just as easy. The whip itself does not have to ever be touched (except on 2 meters). Tuning is done by adjusting the length of the counterpoise. The counterpoise can hang out the window or lie along the floor in the room.

There's nothing else to buy for the antenna. The antenna mounts on the window via a vise-type mechanism. It's also great for you apartment-dwellers who can't put up antennas.

The only "tool" needed for assembly and disassembly is a flat screwdriver.

The Vacationer antenna can be ordered from any store which stocks B&W parts. The number of the antenna is the Model 370-10. The antenna lists for approximately $32.50.

There is a previous model, number 370, which is less in price and does not include 40 meters. If you would like the specifications, write to Barker and Willamson, Inc., 10 Canal St., Bristol PA 19007.

It's a great little antenna and the swr is adjustable to 1.1:1. ■

Tone Decoder Improvements

—another step toward perfection

With a signal conditioner and valid-digit recognizer, you can't go wrong.

Rick Swenton WA1LMV
19 Allen Street
Bristol CT 06010

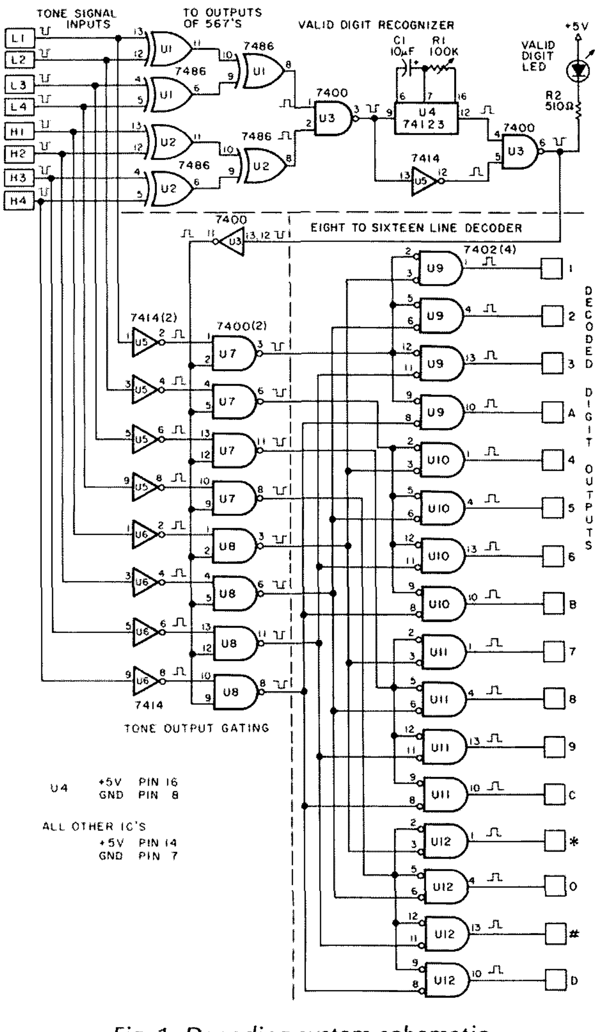

Fig. 1. Decoding system schematic.

The Signetics NE567 is my favorite toy. I'll never give it up. After working on several old telephone company decoders, I realized that they definitely leave something to be desired—especially if you were to attempt to build one from scratch! Also, after experiencing several commercial-quality state-of-the-art DTMF decoders, I realized that while they are terrific decoders, their price is out of sight. That leaves the NE567.

Mr. Everhart* described the limitations of the 567 in a very thorough presentation. However, its limitations can be worked around to yield a high quality, superior performing decoder. The 567 cannot stand alone without conditioning its output. The circuitry presented here is a sophisticated signal conditioner and valid-digit recognizer. It is an improved alternative to separate delay networks on the outputs of all eight 567s. (See Fig. 7 in referenced article.)

The block diagram of this system is in Fig. 2. It consists of two bandpass filters, one for the low-group tones, and one for the high-group tones, two limiters, eight frequency decoders, a valid-digit recognizer/signal conditioner, and an eight-to-sixteen-line decoder. To build your decoder, see Everhart's article for information on building the bandpass filters, limiters, and 567 decoders. The outputs of the eight 567 decoders are then fed into the valid-digit recognizer, Fig. 1. The valid-digit recognizer consists of U1 and U2 (7486 exclusive OR gates), U3 (7400 quad two-input NAND gate), U5 (7414 hex inverter), and U4 (74123 monostable multivibrator).

The function of U1 and U2 is to determine if the 567 decoders are sending only one low-tone signal and only one high-tone signal. The outputs of U1 and U2 are ANDed together by U3 so that the output of U3 (pin 3) goes low only when the following conditions are met: You

*J. H. Everhart WA3VXH, "Toward a More Perfect Touchtone Decoder," *73 Magazine*, November, 1976, pages 178-181.

must have only *one* low tone *and* only *one* high tone.

The next section of the valid-digit recognizer is the delay circuit consisting of U3, U4, and U5. R1 and C1 determine the time delay. The output of the valid-digit recognizer circuitry is U3, pin 3. Pin 3 of U3 goes low only when one low tone AND only one high tone are present and they must remain uninterrupted for the time duration set by R1 and C1. Optimum setting of R1 is from 0.25 to 0.5 seconds. This setting may vary for your particular setup. As a rule of thumb, set R1 to be fast enough for your signaling requirements, but slow enough to reject erratic pulsing. Remember that a condition could exist where a certain voice may be decoded as two tones which happen to be two touchtone™ frequencies. This would meet the requirements of only one low and only one high tone, but would not be decoded if R1 were set correctly.

Next, we use the output of the valid-digit recognizer to gate the outputs of the 567s into the eight-to-sixteen-line decoder. U5 and U6 are 7414 Schmitt triggers. They will further condition the outputs of the 567s and shape the output waveform. U7 and U8 (7400 NAND gates) provide the gating of the 567s to the sixteen-line decoder. Thus, no tone decoding can take place without valid-digit recognition because the outputs of the 567s are not being applied to the sixteen-line decoder unless valid-digit recognition has occurred. The outputs of the sixteen-line decoder, U9-U12 (7402s), are normally low and go high when the digit is decoded.

The system described here is in use at three repeaters in the Hartford CT area (WR1ABM: .28/.88 and 442.85-447.85 and WR1AFU: .75/.15) as autopatch and control decoders and are working well without any problems. With a 0.5-second response time, there has never been a false activation of any function. ■

The All-Wrong Power Supply

—works in spite of itself

Power to the junk box!—and from it.

Usually when one builds a power supply, one takes a currently vogue circuit and uses it verbatim. For solid-state rig advocates, the present norm is using a transformer, a diode-bridge rectifier, and a series pass transistor. While I have no qualms about this circuit, I know many hams who spend time and money looking for the "proper" parts when, in reality, they can use junk box parts in an equivalent circuit.

The circuit in Fig. 1 is the power supply I have been using for my Icom IC-230. It delivers about 3.5 Amps at 12 volts. When one looks at the schematic, however, the circuit *looks* wrong. First, the transformer voltage is too high and everyone *knows* there are four diodes in every power supply worth mentioning. How can it work?

First, consider the transformer, rectifier, and filter capacitor combination. The output voltage with transformer secondary voltage V_t, load current I_l, and capacitor C connected in a half-wave circuits is: $V_{out} = 1.4V_t - I_l/120C$. The ac ripple on this voltage will be: $V_{ripple} = I_{out}/210C$. Inserting our values we find the following: $V_{out} = 1.4(28V) - 4\ \text{Amps}/(120 \times 4 \times 10^{-3}\ \text{Farad}) = 30.87$ volts and $V_{ripple} = 4/(210 \times 4 \times 10^{-3}) = 4.76$ volts. Thus, the output is a dc level of 30.87 volts with a 4.76 volt ac voltage impressed upon top of it. Therefore, we have a varying voltage from 26 to 36 volts at the input to the regulator.

We have just shown why we are using a higher voltage transformer with a half-wave rectifier. The transformer chosen was a surplus one with a 28 V, 4 A secondary, bought for $1.00. This is in contrast to the 18-volt types usually chosen for a similar supply, then operated with a bridge rectifier.

Practically, what these equations show is that if our regulator can follow an input voltage from roughly 25 to 36 volts, we can use this circuit to make a regulated power supply at a variety of voltages. Before slapping a three-terminal regulator on the output and going to look for a "cold 807," one must do a little more designing.

Returning to the voltage output equation, we note that at zero current our voltage across the filter capacitor is 1.4 × 28 or 39.2 volts. This value is the maximum voltage across the capacitor. Then a capacitor with a working voltage of at least 60 volts should be used.

The standard three-terminal regulators have a maximum input voltage of about 35 volts. Therefore, one might damage or destroy the regulator if it were connected directly to the rectifier output. The zener diode (Z) and the resistor (R) in the schematic take this into account. The zener was chosen from the junk box and almost any power-type zener can be used as long as the regulating voltage is below 35 volts.

The value of resistor R can be easily found. The current through the regulator is roughly the base current of the transistor which is roughly the collector-emitter current divided by the gain of the transistor. Since a typical power transistor has a gain of about 50 and our maximum output current is about 3.5 Amps, we see that the base current is about 70 mA. Since our lowest voltage across the capacitor is about 25 volts, we want something like an 8-volt drop with 70 mA or about 100 Ohms.

Although the drop across the resistor is constant, the actual voltage input to the regulator will vary from 17 to 27 volts. This can influence the choice of zeners since a 25-volt zener will only draw power when the voltage is above 25 volts and, therefore, has a smaller duty cycle than would a 20-volt one. Maximum heating on a 25-volt zener would occur with no current drawn by the regulator. In this case, it would be about 10 mA, so a 1-Watt zener should do. The resistor will dissipate 10 volts at 80 mA, so a 2-Watt one will be fine.

The final bit of analysis deals with the diode (D2) on the ground leg of the three-terminal regulator.

This is used to raise the regulator voltage up by .7 V so a "12-volt" regulator will give a 12-volt output.

No analysis will be given of the power transistor since my only suggestions are to heat-sink it well, choose one with a gain of about 50, and a power of about 75 Watts. A 2N3055 is an inexpensive and usually safe choice. The small capacitor across the output is used for protection from oscillation. Although I have never had a supply oscillate, the capacitor is cheap insurance.

Parts List

D1	10A, 60 piv silicon diode
D2	1A, 15 piv silicon diode
U1	7812, 12-volt positive voltage regulator
Q1	2N3055 transistor
R,Z	See text

The supply was constructed on a piece of particle board with plywood sides and a U-shaped cane metal cover for ventilation. A little decorative stain made the XYL joyfully approve of the supply for use in the den instead of being hidden away.

The design of this supply is neither unique nor innovative, but it shows that one can build a power supply from the junk box that really works.■

The Hardhearted Rf Detector

—insensitive to harmonics

Over the years, the thermal, or calorimetric, wattmeter has remained the standard for all measurements of radio frequency power. Unfortunately, calorimetric power meters are very expensive and, therefore, are found only in the laboratory. Almost without exception, the front panel "power" meter found on a radio transmitter is really a peak-reading voltmeter calibrated to approximate a reading in Watts. Any harmonic energy from the transmitter due to misalignment or component failure can cause this meter to soar to a reading much higher than the true rms power output. The obvious solution has been overlooked. Every radio transmitter can be equipped with a simple power metering circuit offering accuracy and insensitivity to harmonics approaching that of a thermal-type meter.

In place of the usual detector followed by a capacitor input filter, the improved circuit will employ a choke input filter. This circuit, properly designed, will develop an output equal to the average dc level of the half-wave pulsating dc from the detector (resemblance to the choke input power supply filter is not accidental). An average reading voltmeter may be calibrated to read the true average power dissipated by a load. The ratio of average power to rms power remains relatively constant for extreme distortions of the sine wave, while the power, computed by the square of the peak voltage divided by twice the load resistance, may vary several decibels.

This simple high-accuracy circuit has but one special requirement. The input inductor must be chosen so that its effective inductance remains above the critical value required for voltage regulation to the average level over the frequency band of interest. Therefore, a choke approaching self-resonance at the operating frequency would not be suitable. The critical value is computed by: $L_{min} = (0.060/F)R_L$ henrys.

A typical circuit for use at a 50-Ohm termination, where $X_{c1} \leq 5$ Ohms and $X_{c2} \leq R_L/10$, is shown in Fig. 1, and the results from low-frequency (F = 40 kHz) test circuits (Figs. 2 and 3) are shown in Table 1. ■

Custom-Designed Power Supplies

—try the 723

Bargain-basement fanatics will love this new approach.

Carl S. Griebno K2GEJ
R.D. #2 Kline Drive
Pennellville NY 13132

LSI, microcircuits, mass production, and high component costs are but a few of the many reasons that are leading to the demise of amateur radio home brewing. In spite of this, there are plenty of well-documented circuits for you to select from that will not wind up costing a fortune to build (see any issue of *73*). Unfortunately, most of them require a power supply which can wind up with a price tag as large or larger than the rest of the project.

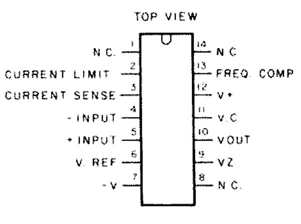

Fig. 1. Pin designation for the 723.

If you are considering bargain-basement electronics, you should also anticipate the problems associated with quality, reliability, and aesthetic appeal. There are precious few units I would let adorn my operating table.

This article will show you how to custom-design your next supply, featuring the widely used 723 IC regulator. This will allow you to have the supply best suited to your application and provide the quality, reliability, and features you desire. All this is at a surprisingly low cost. You should find the design calculations relatively easy and the assembly straightforward.

The 723 Chip

There are many features of the 723 IC, one of which is a temperature-compensated and amplified reference voltage output (Fig. 1, pin 6). This output voltage is typically 7.15 volts and capable of supplying up to 15 mA of current. Current-sense terminals (pins 2, 3) allow the user to select the upper current limit of the supply. Also, the 723 has a built-in error amplifier directly coupled to an "onboard" series pass transistor. This combination is capable of supplying up to 150 mA. The line and load regulation of the supply will be typically 0.1%. Some of the 723's other features are low current drain, low temperature

drift, and high ripple rejection. Another good feature is the $.35 to $.50 price tag in single quantities. It is, in fact, uncommon not to find a 723 stuck somewhere in an OEM industrial supply.

External Components

Before we get into the design calculations, take a look at Fig. 2. T1, C1, and Q1 (or Q1 alternate) are the only external components needed for this supply, the remainder of the components being mounted on the PC board. Looking at T1, you can see I have drawn a center-tapped transformer. If you have this type of transformer, diodes D1 and D2 are used in a full-wave, center-tapped configuration using pads C, D, and E on the PC board. If your transformer has no center tap, use diodes D1 through D4. Connect the transformer leads to pads C and D on the board and you have a full-wave bridge configuration. I have found that a 12-volt filament transformer with a bridge rectifier works extremely well for output voltages from 2 to 7 volts and a 24-volt control type transformer with a bridge rectifier is an excellent choice for output voltages of from 9 to 25 volts. Make sure the transformer secondary current rating is high enough for your supply design. There will be some more comments about T1 later on.

Diodes D1 through D4 must be chosen to handle the current you design the supply for. The popular 1N4000 series diodes are excellent for current levels of up to 1 Amp. The 3-Amp epoxy "bullet" rectifiers are so inexpensive that I try to keep some on hand all the time (MR 500 series). If you are fortunate enough to be able to obtain some Motorola MR 751s, a 6-Amp device, these also may be used on the board. The diodes should have a piv rating of at least 50 volts. By using a glass-epoxy board material with 2 oz. copperclad, the runs on the board are easily wide enough to handle 6 Amps with less than 10° C temperature rise. For design currents higher than 6 Amps, the rectifiers, filter capacitor (C1), series pass transistors (Q1, alt.), and C3 may be wired externally with heavy wire. The circuit board can then be wired in as a control system for the regulated supply. (See Fig. 3.) If you use the board in this manner, do not use R7, which is the current-sensing resistor. Mount the fuseholder for F2 externally, instead of in the hole provided on the PC board, and fuse for the design current. Although not shown in Fig. 2, it is a good idea to wire diode D6 at the output terminals of the supply. This is a "free-wheeling" diode that will protect the regulator board from any inductive transients coming back to the supply from the load (e.g., a T-R relay). A 3-Amp, 200-piv device is suitable for D6.

At this time, it is worth mentioning that Q2 (Fig. 2) will require some heat sinking at the higher current output levels. To do this, you might even wire an externally mounted 2N3053 or 2N3055 to the Q2 pads located on the PC board.

Unless you have a river flowing nearby to cool Q1, a bit of caution must be exercised in what is done here. A 2N3055 has a power dissipation specification of 115 Watts if you can keep the case temperature at 25° C (77° F). Following a derating curve for this transistor, Q1 can dissipate up to 63 Watts at a case temperature of 100° C (212° F). What this translates to is approximately 4 Amps of current with a 15-volt drop from collector to emitter. Allow one 2N3055 for every 4 Amps of output current and, by all means, heat-sink them! Also, if you sink Q2 well, it is capable of driving up to four 2N3055s connected as shown in Q1 (alt.). The other alternative, as previously mentioned, is to externally mount Q2 and wire it into the board. The bottom line here is to keep

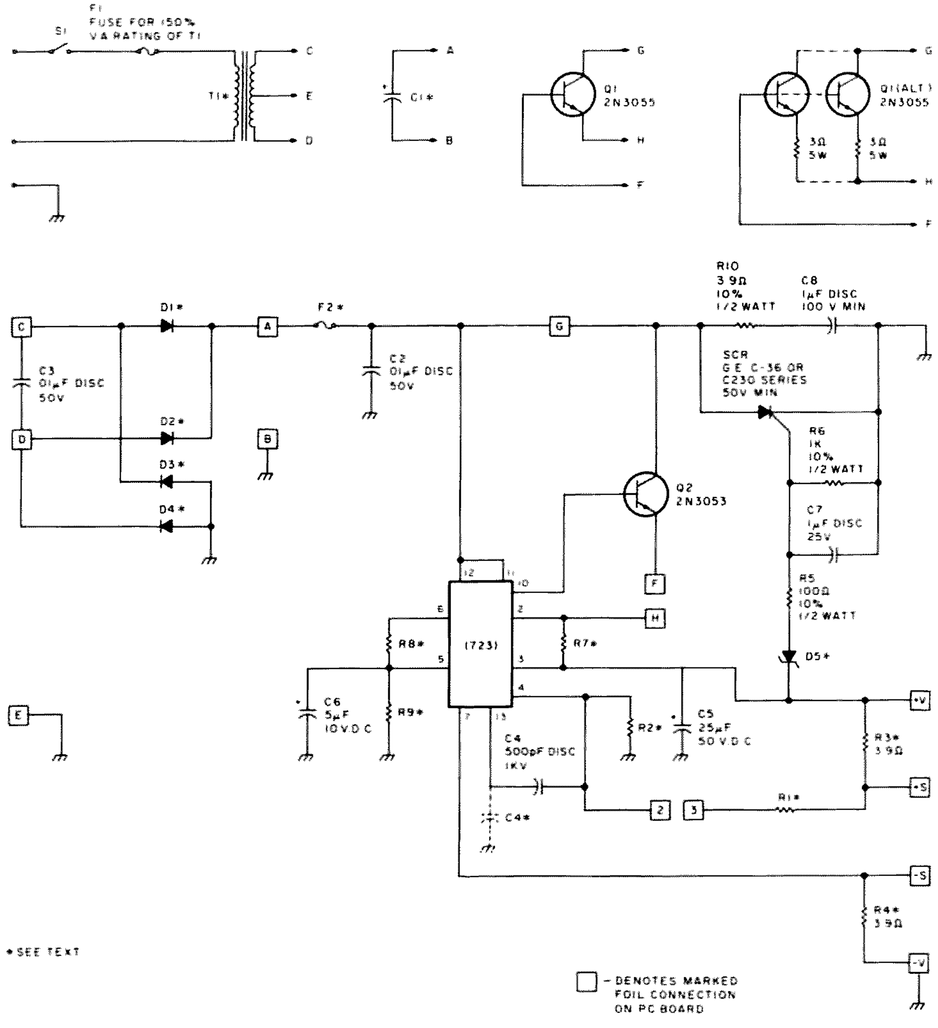

Fig. 2. Power supply schematic diagram.

the Q1 and Q2 case temperatures below 100° C to achieve the best reliability.

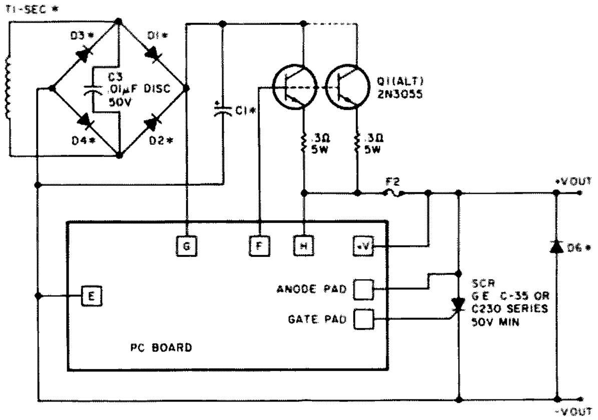
There will be a special section on C1 later on in this article.

Overvoltage Protection (ovp)

The ovp circuit, an SCR crowbar-type, is optional in that it has no effect on the operation of the regulator. If, in fact, you opt for a variable supply, it can be a nuisance. But, if you have a nice new SSB rig, it can save you a bundle. The circuit consists of an SCR, C8, R10, C7, R6, D5, and R5. The only variable in the circuit is zener diode D5. The zener should be rated 2 to 3 volts higher than the regulated output voltage and have a 5% tolerance. The ovp circuit operates as follows: Any rise in the output voltage above the rating of D5 will fire the SCR. After firing, it will remain in the on state until fuse F2 blows, thereby protecting the load from a gross overvoltage. Choose a rating for F2 approximately 20% above the design current. Resistor R6 prevents any anode-gate leakage current from inadvertently firing the SCR. Capacitor C7, along with R5, acts to prevent any power line switching transients from firing the SCR. This is especially true under no-load conditions. C8 and R10 form a dv/dt (voltage change to time change) network that prevents the SCR from turning itself on due to high rate-of-rise voltage excursions across the device. There are anode and gate pads for the SCR clearly marked on the board. Also, there is a hole drilled in the common foil, just below the SCR mounting hole, for the cathode connection. When mounting the SCR, use the insulating washer that usually comes with the device. The stud is the anode connection and, without the washer, the mounting nut will come in contact with the common foil. If there is no insulating washer with the SCR, one can be easily fabricated by peeling the copper from a small piece of circuit board material. The unclad material may then be used as the washer.

Remote Voltage Sensing (rvs)

Rvs, a feature of this supply, is seldom discussed in literature. To better understand the value of rvs, let's take a look at what can happen when it isn't used. All electrical connections are imperfect, as they have some resistance associated with them. The same holds true for wire. Consider a connector resistance of 50 milliohms and a power lead resistance of the same magnitude. That is like putting a resistor with a value of 0.15 Ohms (two terminations and a conductor) in each lead of the power cable. This comes to a total resistance of 0.3 Ohms. That doesn't sound like much, but, when multiplied by 10 Amps, the resultant voltage drop in the cable is 3 volts. Not good! Now, if we could sense voltage out at the load, the cable drop would still be there while the regulator is being "fooled" into putting out enough extra voltage to compensate for this drop. With this supply design, all that has to be done is to run two small wires in parallel with the power cable wires. Tie them together at the remote load location and you have rvs. (Connect the +S and the +V wires together, also the −S and the −V wires.) The reason you may use smaller wires is due to the fact that only a few milliamps of current are required to drive the error amplifier in the 723. Remember, the higher the current levels that you work with, the more important it becomes to use rvs. R3 and R4 are shown to be 3.9 Ohms. Any value you happen to have between 2 and 10 Ohms will be satisfactory here. If you do not wish to use remote sensing, a jumper may be installed in place of R3 and R4.



NOTES ☐ - INDICATES MARKED FOIL CONNECTION

*SEE TEXT

Fig. 3. Wiring arrangement when the 723 is used as a control system for an external regulated supply. Run rvs wires from PC board. Do not use jumper (Fig. 4).

Let's Regulate

The regulator portion of this supply consists of C2, R8, R9, C6, the 723 IC, C4,

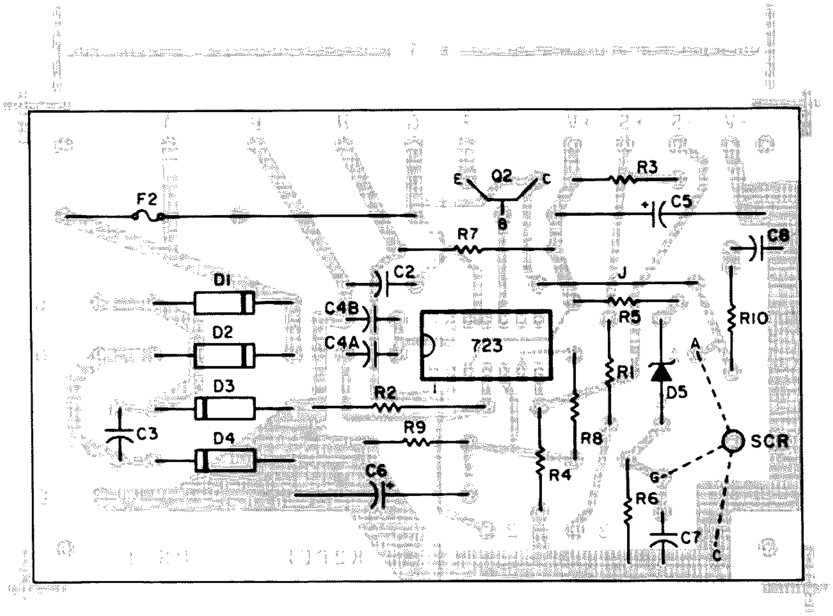


Fig. 4. Component layout.

Q2, Q1, R7, C5, R2 and R1 (Fig. 2). The circuit, when constructed with a jumper between pins 5 and 6 of the IC (in place of R8), is for output voltages of between 8 and 24 volts. Do not use R9 and C6 in this case. Remember our reference voltage (V_{ref}) output of 7.15 volts? In this connection, the reference voltage is applied directly to the (+) input of the error amplifier. Therefore, the (−) input of the error amplifier *must* be 7.15 volts in order for the 723 to be in a stable condition at V_{out}, pin 10. Let's go through a simple calculation and see how we can design for an output voltage of 13.5 V dc so that you can run your new 2 meter rig or maybe a mobile unit brought in for the winter. Looking at the schematic, we see that the voltage at pin 4 of the IC, the (−) input of the error amplifier, is derived from a voltage divider R3, R1, pads 2 and 3, and R2 and R4. R3 and R4 are very low value resistors that allow for rvs and, therefore, have no effect on our calculation. Pads 2 and 3 allow for an external voltage adjustment if desired. So now we're down to two resistors, R1 and R2. The value of R2 is not critical (somewhere between 1k and 3k is fine), but must be chosen first. Let's say a 2k resistor is handy for R2. The voltage across R2 must be equal to our reference supply, again 7.15 volts. Our supply is supposed to operate at 13.5 volts, so the voltage across R1 will be 13.5 volts minus the drop across R2 (7.15 volts). A proportion will give us the value for R1. The equation is as follows:

$$\frac{R1}{V\,R1} = \frac{R2}{V\,R2}$$

Solve:

$$\frac{R1}{13.5 - 7.15} = \frac{2k}{7.15}$$

$$7.15 \times R1 = 6.35 \times 2k$$

$$R1 = \frac{6.35 \times 2k}{7.15} =$$

1776 Ohms.

Use 1800 Ohms, 5% tolerance, 1/4- or 1/2-Watt.

This will give you an output voltage very close to 13.5 volts. If you would like to trim V_{out}, use a 1300-Ohm resistor for R1 and wire a 1k variable resistor to pads 2 and 3. This will give you 13.5 volts output at approximately 50% of pot rotation, giving you plenty of trim range. Otherwise, don't forget to jumper pads 2 and 3 if you use a 1.8k resistor for R1. When using the 8-through-24-volt connection, place C4 at C4A, Fig. 4. C4 is the compensation capacitor and provides a high-frequency breakpoint in the error-amplifier circuitry, preventing unwanted oscillations.

In order to use the supply for voltages of less than 7 volts, only minor changes need be made. Resistor R2 will *not* be used. Place a jumper in pads 2 and 3 and also in place of R1. In doing this, the output voltage will be placed directly on the (−) input of the error amplifier. Let's say we want 5 volts output for some TTL circuit we have or maybe that new microcomputer the UPS man just delivered. All that has to be done is to divide the 7.15-volt reference supply down to 5 volts. This calculation will be the same as the previous one. Choose R9 (any value from 1k to 3k). Let R9 = 1k. This time the equation is:

$$\frac{R9}{V\,R9} = \frac{R8}{V\,R8}$$

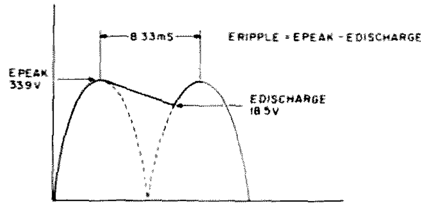
Solve:

$$\frac{1k}{5} = \frac{R8}{7.15 - 5}$$

$$R8 \times 5 = 1k \times 2.15$$

$$R8 = \frac{1k \times 2.15}{5} =$$

430 Ohms.



A

CAPACITOR DISCHARGE TABLE

% DISCHARGE	TIME
80	0 25 RC
60	0 50 RC
50	0 75 RC
37	1 00 RC

B

Fig. 5. C1 calculations.

Use a 5% tolerance, 1/4- or 1/2-Watt resistor. Now we have the R8 and R9 values we need for our 5-volt supply. Capacitor C6 is used to filter out any "white noise" present in the V_{ref} output and in R8. Also, place C4 at C4B, Fig. 4.

For output current levels of 6 Amps or less, R7 must also be calculated. R7 is the current-sense resistor and its value will set the *maximum* output current of the supply. When the R7 voltage reaches 0.6 volts, the 723 will start reducing the output voltage in an attempt to keep the output current constant. This calculation is the Ohm's Law relationship R = E/I, where R is the value of R7, E is 0.6 volts (the specified CL − CS voltage), and I is the supply current limit. The calculation for R7 is as follows: R = 0.6/2 Amps = 0.3 Ohms. Don't forget the power dissipation in R7. That calculation is as follows: P = E × I = 0.6 × 2 = 1.2 Watts. At the risk of not having current limiting, or waiting until you can procure this low value resistor, a jumper may be used in place of R7. As long as R7 is in place, the supply can even stand intermittent short-circuit conditions at the output terminals with no resulting damage.

If you've read this far, it's time to get a cup of coffee or maybe a nice cold 807. We still have a little more to go.

C1 Calculations

There are various ways to find a value to be used for C1; most of them use higher mathematics. To me, that is an exercise in futility. What I will explain here is a simple method that works very well, and can be easily verified if you have access to an oscilloscope. Again, for the sake of numbers, let's work on a 13.5-volt, 2-Amp supply design. I will assume you have found in your junkbox a 24-volt center-tapped transformer. The first step is to add 5 volts to your design output voltage. The reason for this is to make absolutely sure that there is enough voltage to overcome the base-emitter drops (V_{be}) in the regulator transistors, and give the series pass transistors some "operating room." Adding 5 to 13.5 volts gives us 18.5 volts. This value is placed at the point labeled E DISCHARGE, Fig. 5. Now, suppose you would like to use the full-wave, center-tapped connection as previously mentioned. Divide the 24-volt rating by two. The reason this is done is that you are only using half the transformer winding by connecting the center tap to common. This will give you 12 volts, which is an rms value. To find E PEAK, the value C1 will charge to, multiply 12 volts by 1.414 (E PEAK = E RMS × 1.414). This value, 16.97 volts, does not meet the minimum value of 18.5 volts required by the supply design. E PEAK should be a minimum of 5 volts higher than E DISCHARGE, or the filter capacitor (C1) will become very large (ex-

pensive). This dictates the use of the 24-volt transformer in a bridge rectifier configuration. It also means that you have to come up with two more diodes. The value for E PEAK will now be 24 × 1.414 or 33.9 volts. Now we have 15.4 volts before we're down to the E discharge value. The next step is to find out what percent 18.5 volts is of 33.9 volts. Divide E DISCHARGE by E PEAK. 18.5/33.9 = .5457 or 54.57%.

Now go to the capacitor discharge table in Fig. 5 and find a percentage value closest to the above calculation, in this case 50%. Across from this you will find 0.75 RC. What this means is that in the 0.75 time constant, the capacitor will discharge to 50% of its initial value, E PEAK. Now R × C is a formula we can work with to find the value for C1. Remember t = RC? To find a value for t to be used in this formula, solve the equation 8.33 milliseconds = 0.75t. The time value, 8.33 milliseconds, does not change, as it is the period between the pulsating dc peaks that charge C1 (60 Hz line frequency). 0.75 is the table value reached by the E PEAK, E DISCHARGE calculations. Solving the equation, we get: t = 8.33/0.75 = 11.1 milliseconds.

We now need a value for R to complete our C1 calculation. This value can be found from R = E/I where E is the E PEAK value and I is the supply current design value, or 2 Amps. Solving this equation, we get R = 33.9/2 = 17 Ohms.

To find the value of C1, use t = RC. Solving this, we get: 11.1 milliseconds = 17 Ohms × C. C = 11.1/17 = 0.652. To get uF, multiply 0.652 × 1000 = 652 uF for C1. Now 652 uF is the minimum value. Any capacitor of this value or larger is suitable. The voltage rating for C1 has to be greater than E PEAK. In this case, a 50 V dc unit should be used. This method is a bit arduous, but, nonetheless, it's a lot easier than some other methods.

Potpourri

I would like to make some more comments about T1 at this time. Transformers with secondary current ratings of two to three Amperes are very reasonable. If you would like to design a 12-volt, 10-Amp supply, the transformer cost may become quite high. Remember the older tube-type TV sets? The power transformer used in these sets is good for 350 Watts continuous duty. In the *Radio Amateur's Handbook*, in the power supply section, there are excellent instructions on rewinding transformers. Also, in the section on construction practices, you can find a copper wire table that will guide you in selecting the right size wire for your new secondary winding. Rewinding is not difficult and your efforts will be well rewarded. Another advantage is that rewinding enables you to keep the Q1 power dissipation down by reducing the E PEAK (Fig. 5) value to a reasonable level for your supply design.

At no place in this article have I mentioned tying common (−V) to the chassis. Also, on the PC board artwork (Fig. 6) you will not find any mounting holes in the common foil. This is done for two good reasons. The first is safety! Connect that third wire (green) in your power cord to the chassis. All of your equipment should be well grounded. The second reason is for convenience. With a floating supply, the positive and negative connections may be treated just like a battery. Remember that microprocessor the UPS man just delivered? Just found out you needed a negative supply for some PROMs? Build two of these supplies. Tie the positive output of one to the negative output of the other and you have a plus/minus supply. The applications are unending.

In Summary

I believe an outline of the steps you need to go through in designing this supply is in order. First, the regulated output voltage and rated current must be selected. If the voltage is above 8 volts, calculate the values for the R1 and R2 voltage divider. If the voltage is 7 volts or less, calculate the R8 and R9 voltage divider. If R7 is used, calculate that value. Select zener diode D5 in the ovp circuit if used. Select resistors R3 and R4 if rvs is to be used. Decide on the number of transistors to be used at Q1 or Q1 (alt.), and select the correct diodes for D1 through D4. Finally, run through the T1 and C1 calculations.

This sounds like a lot, but many of the above steps are quick and easy. The remainder of the components mounted on the PC board are common to all designs.

The 723 is a great IC. Give this supply your best shot and I'm sure you'll be very happy with the results. For those of you who wish, I can supply a high-quality predrilled circuit board for this article. The cost is $4.50 postpaid. An SASE will bring an answer to any questions you may have. ■

A Touch of Class

—nifty $35 operating console

For comfort and convenience, this bench can't be beat.

Horace M. Lewey, Sr. WA4CUD
2405 Cyprus Street
Greensboro NC 27405

Console design can make a world of difference in your enjoyment of ham radio. Comfort, convenience, and ease of operation were the criteria set for the construction of this operating bench. The finished product provides all that and is very strudy as well.

Figs. 1, 2, and 3 show how everything goes together. The parts list gives all the materials you will need.

You should countersink all holes for the bolts and screws, fill them with plastic wood, and sand them smooth before painting or staining. This will give you an attractive finish. Leave a one-inch overhang on the sides of the top shelf and the desk-top, as you can see in the photo. ■

How To Bury Coax

—the garden cultivator technique

Ye keep what ye sow.

Max Holland W4MEA
Rt. 3, Rawlings Lane
Madisonville TN 37354

A ground plow is often used to bury coax cable. This special device usually is attached to the rear of a tractor and can put the cable down 8-12 inches in the ground. See *Ham Radio*, May, 1970, page 66, for procedure.

Having no access to a ground plow, I had to use the Armstrong method. It is difficult to bury 100 feet of coax cable in this manner. Using the tip of a chain saw to cut a slot in the ground is dangerous and is hard on the chain.

My neighbor, WA4KJA, has a garden cultivator which has been in his family since the 1930s. By changing to a narrow plowshare which was made from a piece of band iron 1½ inches wide, we were able to make our own ground plow.

The work is still hard, but it is easier than using a shovel. The narrow cut in the lawn disappears after several weeks.

The garden cultivator is a Planet Jr. made about 1935. Over the past 50 years of amateur radio, people have operated mobile from cars, airplanes, boats, bicycles, balloons, lawn mowers, go-carts, and tractors. To the best of my knowledge, this is the first time anyone has operated from a garden cultivator. The rig is a TR-22 with 1-Watt output. The antenna is a 5/8-wave whip. The antenna pattern will change depending on the depth of the cut.■

Mobile Antenna Ingenuity

—cheap HF radiators

A Kool-Aid budget, a Champaign result.

George M. Ewing WA8WTE
P.O. Box 502
Cheboygan MI 49721

Four or five years ago, there was a terrific bargain at a northern Michigan hamfest. I unloaded a junky Hallicrafters S-38 for fifteen dollars, and spent the money immediately on a cardboard carton labeled "Mobile Stuff." Along with a lot of really useless junk, I found a Hustler mast, a bumper mount, three resonators for 80, 40, and 20, a desk mike, and twenty feet or so of good coax. The mobile antenna was bolted to the rear bumper of my trusty Barracuda right there in the hamfest parking lot, and, with an aging NCX-3 and a borrowed Heath HP-13 supply, I was on the air almost immediately and enjoyed several years of rewarding low-cost mobile operation.

Almost four years later to the day, while visiting some friends at a conference in Lansing, Michigan, I came out of a motel to behold a horrible sight: The mast, mount, and the eighty meter resonator had been ripped off, leaving the chrome bumper itself twisted like a pretzel! Fortunately, the rig itself was safe, still tucked under my pillow in the motel room, and I had purchased a spare resonator for a couple of dollars the year before. For the rest, I headed straight for my (former) auto insurance company, Divestiture & Bombast Mutual.

Following lengthy negotiations, I left the insurance office with ten measly dollars in search of a new antenna and insurance carrier. One look in a catalog, which listed the mast section itself for over twenty dollars, was so discouraging that I shelved the whole project, resolving to limit my mobiling to VHF until another hamfest bargain came along.

Several years more went by, and I replaced the venerable Barracuda with the bent bumper because I could no longer stand 10 miles per gallon on premium gas. A long Thanksgiving vacation trip to a science fiction conference in Champaign, Illinois, was coming, and, while I now had a good 2m FM rig, I would be out of range of repeaters for a good part of the journey. I decided to try and build a replacement for the missing Hustler. I had managed to come up with a spring similar to the one on the original bumper mount for a dollar from a CB friend. This left about nine bucks in the fund, no machine shop facilities at hand, and a few days left before Thanksgiving. Could it be done? Of course!

The Mast

After some thought about aluminum or steel conduit, a helically-wound PVC pipe, and other substitutes, I decided to go with a rigid copper pipe for the mast. It was sturdy, not too expensive, and an excellent conductor. Two sizes were available at the local hardware store, ½" and 3/4". The trick would be to come up with fittings to match the 3/8" × 24 threads on the remaining resonators, using only simple hand tools and hardware available in a small-town corner store the Wednesday before Thanksgiving.

The 3/4" tubing was sturdier, heavier, and required two fittings less than the ½" size. It would also have a slightly lower resistance loss at rf frequencies. On

Changing resonators.

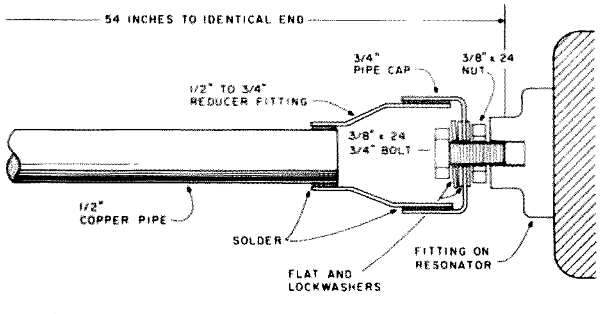

Fig. 1. ½"-pipe version. Mast-to-resonator fitting.

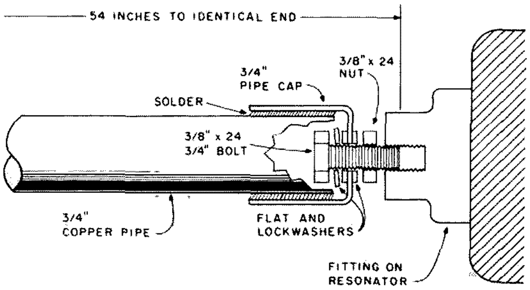

Fig. 2. 3/4"-pipe version. Mast-to-resonator fitting.

the other hand, its larger cross section and wind resistance might make it "whippier" in crosswinds on the freeway.

The ½" tubing was chosen because it was lighter, cheaper, and more closely matched the dimensions of the original Hustler chromed-brass mast. Cost was about 45 cents per foot, or close to $2.50 for a 54-inch length. Had time allowed, used copper pipe could have been obtained for about half this amount, but it would have required extensive cleaning.

Mast-to-resonator and mast-to-spring adapters were made up using store-bought plumbing parts (see Fig. 1). The same design would work for a 3/4" mast, simply by omitting the ½"-to-3/4" reducer fittings (see Fig. 2). The 3/4"-diameter ends are needed for clearance for the hardware.

Making the Adapters

Clean the tubing and fittings carefully with a rag and automotive rubbing compound or some other mild abrasive. Salt and vinegar will also clean the copper chemically, but I found the rubbing compound much faster. Clean the residual abrasive, fingerprints, etc., off the parts with a solvent like alcohol, acetone, or carburetor cleaner. Do this outdoors or in a well-ventilated area, and keep the solvent away from sparks and flames. Handle the parts with gloves or a clean rag, and you'll be able to solder them easily with ordinary rosin-core solder.

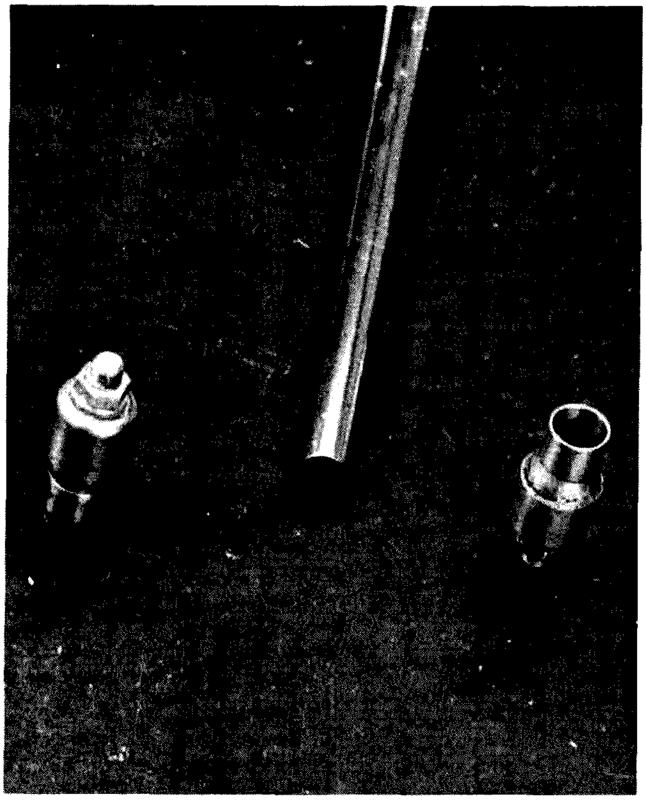
Center-punch the 3/4" end caps and drill them with 3/8" holes to assemble the fittings. Assemble the bolts, nuts, and lockwashers before you do the soldering. Assemble the hardware as per the diagram, and then solder with a small propane torch, gas stove burner, or large (250 W+) iron.

After you have assembled the mast, clean it again with the rubbing compound and the solvent, especially the areas discolored by soldering, and then give it several coats of clear spray lacquer or urethane varnish to protect it from corrosion.

The total cost for the pipe, hardware, and fittings was just under five dollars, well within my cost goal.

The One-Dollar Bumper Mount

Refer to Figs. 3 and 4. The trusty Barracuda had been replaced with a '75 Chevy Monza hatchback which got better gas mileage but featured an odd rubber-covered bumper that made mounting difficult. The base for the mount was made from a piece of ½" marine scrap plywood, but almost anything will do if it's sturdy —sheet metal, Masonite, etc. The brackets were sawed off of the front panel from a TD-2 microwave bay that happened to be lying in the station junk box. An aluminum channel from a busted storm door or more scrap plywood would be just as effective. The insulating plastic plate is the only tricky part, as it has to be very strong mechanically. I used a piece of heavy phenolic from the fuse block in a piece of surplus equipment. A scrap of heavy Plexiglas™ or several pieces of scrap circuit board epoxied togeth-



3/8" × 24 adapters for the ½" copper mast.

Impedance and Other Ogres

—another look at swr

You will now understand standing wave ratio.

The subject of understanding the effects of swr (standing wave ratio) has been explained in various articles a dozen times over in recent years. Still, many amateurs look at the "percent power reflected" markings opposite the swr values on an swr meter and are confused. For instance, next to an swr value of 3:1 there is marked "25% power reflected." The usual belief is that 25% of the total power which the transmitter is groaning to put out never makes it to the antenna to be radiated. Instead, it is rejected (reflected at the transmission line/antenna junction) and goes bouncing endlessly back and forth between the transmission line/antenna and transmission line/transmitter junctions. In other words, it is consumed or lost in the transmission line and/or plays all sorts of havoc with the transmitter output stages. This is not the case, of course, but the "percent reflected" scale of an swr meter does produce an image in one's mind that is hard to alter.

Rather than start talking about transmission lines, mismatched loads, etc., there is something much more fundamental than that which one should understand to have swr become clear. It has nothing to do with electronics and just goes back to basic ac electrical circuits. Understanding it (and not just skimming over the idea) will make the whole subject of swr and its effects in radio applications clearer.

Normally one thinks of power as just being the product of voltage times current, and indeed it is, except that one has to put a little "extra" into the formula when speaking of ac circuits. In Fig. 1, a sine wave of voltage and current is shown as it appears across a resistor. The power dissipated at any *instant* is the product of the voltage and current at that *instant*. In the example, the voltage has a peak value of 30 volts, and the current a peak value of 20 Amperes, so the peak power is 600 Watts. When both the voltage and current go into the negative half of their cycles, you have -30×-20 (at the peak negative excursion), so the peak power is still a positive number. By going back to the ac textbooks, one can confirm that by multiplying the rms values of voltage and current, the resultant obtained is average power. But, that is not important at the moment; the only important point is that one multiplies the voltage and current at any instant to get instantaneous power.

In Fig. 2, the voltage and current waves have their same peak values, but because they appear across a reactive load, not a pure resistor, the waves are displaced in time. However, the power formula still holds true at any *instant* (voltage times current). So, if the voltage and current are multiplied at every instant, the dotted peak power line shown will result. The interesting thing about this power wave is that is goes negative. So, the actual overall power

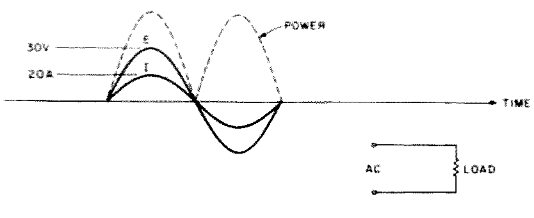

Fig. 1.

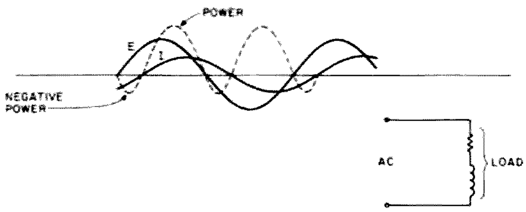

Fig. 2.

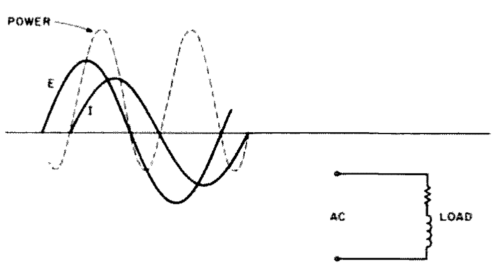

Fig. 3.

absorbed by the circuit is the net "positive" power minus the net "negative" power. This idea of negative power is where our little gremlin comes into play. The concept is that this negative or imaginary power represents power which the load will not accept. Therefore, although the source of power is able to supply power to the load as shown in Fig. 1, when the load is not purely resistive it cannot accept all of the power the source is capable of supplying. Said another way, during the portions of the voltage and current waves when they are both positive, the source is delivering power to the load. During the portions of the voltage and current waves when *either* one of them is negative, the load is returning power to the source that it could not absorb. Where is this power in between the time it is "offered" and then "rejected"? It's in the electromagnetic or electrostatic fields associated with reactive elements—inductors or capacitors. It doesn't bounce around like a Ping-Pong™ ball between the source and the load.

To obtain the net average power a load takes, one has to take into consideration not only the voltage and current values, but also the time displacement between the voltage and current waves. In basic ac circuits, the power formula then becomes $P_{AV} = E_{RMS} \times \cos \phi$. $\cos \phi$ is, of course, what electrical power people refer to as the "power factor."

There are three simple things one can learn from the simple ac circuit before going on to the radio applications of the idea presented. Note in Fig. 1 that the resistor absorbs a certain amount of power. Remember that only resistors can absorb and dissipate power. Now, if we have the load of Fig. 2 and we want the resistor part of the load to absorb the same amount of power as the resistor in Fig. 1, we have to do something. One thing we can do, so that the net power in Fig. 2 comes out the same as the net power in Fig. 1, is raise the voltage across the load and hence the power "offered" to the load. The load will reject the same proportion of the total power as before, but if we "pump" enough power into the load, we can get the resistive element of the load on Fig. 2 to absorb the same power as the load of Fig. 1. This means increased input power and greater voltages and currents in the circuit as shown in Fig. 3.

The other approach is to "match" the load. That is, if we cancel the inductive reactance in the load of Fig. 2 by a series capacitance reactance of the same value as shown in Fig. 4, the voltage and current wave across the combined resistor/capacitor/inductor load will again become as shown in Fig. 1. Since the reactive elements cannot dissipate power, the circuit becomes the equivalent of Fig. 1, and no extra power need be pumped into the load to have the resistor dissipate the same power as in Fig. 1. This is all true, however, only at one frequency.

The loads in Figs. 1-4 are shown as being connected directly to a source of power. However, what if the load is connected to the power source over a long pair of wires, each side of which has some resistance, as shown in Fig. 5? If the load is a resistor, it doesn't take too much exercise of Ohm's Law to see that the power available from the source will be divided between the resistance of the load and the resistance of the wire pair in a manner depending on the relative value of the resistances. Let's assume that the resistance of the wire pair is a small fraction of the resistance in the load. If the load now becomes a combination of resistance and reactance *and* the power source is increased to maintain the same power in the load resistor, the power lost in the wire resistance will also increase. But, this is only because more current must flow in the entire circuit as per Fig. 3. The wire resistances will absorb *slightly* more power, but they do not absorb the rejected or reflected power because of the combined resistive/reactive load. Again, only resistances can dissipate power. So, even if the load becomes reactive, as long as the resistance in the load is large in value compared to the resistance of the wire pair, the power lost in the wire pair is not going to become significant.

When the foregoing simple circuits are "elevated" to radio frequencies, none of the fundamentals described really changes. Some new elements are introduced, of course. The wire pair is now a transmission line with a characteristic called impedance, and a *time* element is introduced. That is, power cannot instantaneously go from the source (now a transmitter) to the load (the antenna). This time factor, of course, is very short, but, nonetheless, it does exist. That is why transmission lines have, besides impedance, a characteristic called velocity of propagation. So, one has to speak about power traveling along a transmission line. For instance, in Fig. 6(a) we will assume that we have a "matched" system. That is, the transmitter is designed for 50 Ohms output, the transmission line has 50 Ohms impedance, and the line is terminated in a 50-Ohm antenna. The transmitter is turned on only long enough to generate one cycle of sine wave current, which we'll call the incident, or forward, wave. Since everything is matched, the load completely accepts the power. If we leave the transmitter on continuously, we will have a continuous string of current waves traveling down the line and delivering power to the antenna. Note that although the current waves pass current down the line, when there is a continuing series of waves they will appear to stand still along the trans-

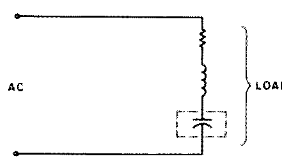

Fig. 4.

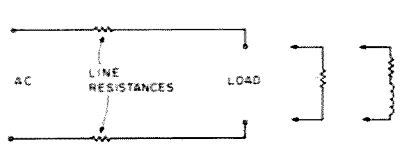

Fig. 5.

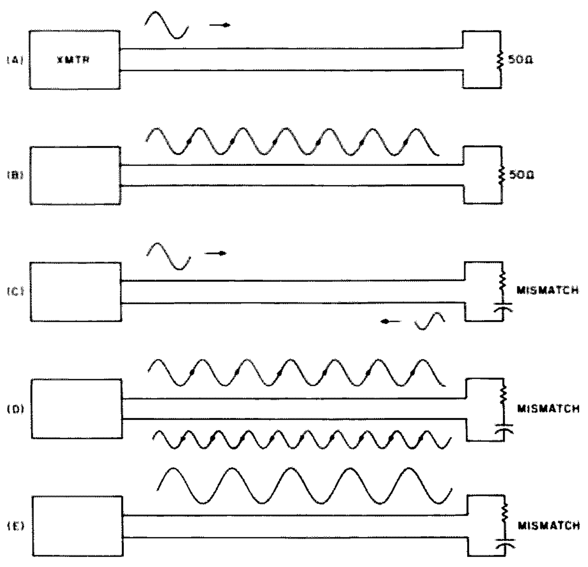

Fig. 6.

mission line.

If in Fig. 6(c) we have a mismatched load and again send a single current wave down the line, we are going to get back from the load a reflected wave. If continuous power is applied to the line, there will be continuous strings of incident and reflected waves. Since the strings are continuous, some incidental waves will always be present at any given point along the line. Therefore, at any given point and at any given instant, the resultant wave will be formed from the combination of the values of the two waves. At some points they will reinforce each other, and at some points they will subtract from each other. One probably thinks of various optical effects where two light sources interact to produce a seemingly stationary light interference pattern. Much the same thing happens on a transmission line. The result of the traveling incident and reflected wave is a resultant stationary wave. Stationary, that is, in respect to its position along the transmission line. Since the resultant stationary wave stands still, it is referred to as a "standing" wave. For example, the resultant of the wave shown in Fig. 6(d) might look something like the standing wave of current shown in Fig. 6(e).

If one can grasp this basic concept of a standing wave, the rest of the ideas surrounding standing waves, what to do about them, how to interpret swr meter readings, etc., will not be difficult. If the ideas presented so far seem a bit unclear, one might go back over them a few times. Particularly, one should understand the simple ac circuit mentioned at the start of the article and be sure that one understands what rms values mean for voltage or current values.

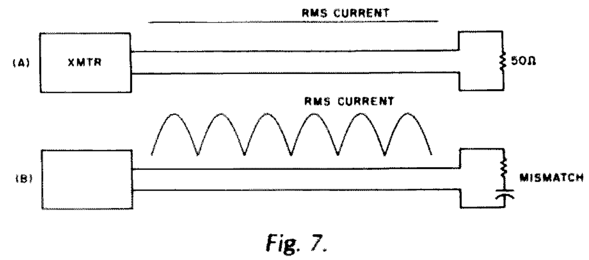

Fig. 7.

If one now feels comfortable about the basic idea of a standing wave, one can accept the information presented in Fig. 7. Instead of dealing with instantaneous values of a current wave, these figures represent the rms current, or the current that one would read along the line with a regular rf ammeter. In the case of Fig. 7(a), the current is the same at any point along the line since the system is matched throughout and there is no reflected current wave. In Fig. 7(b), where a mismatch exists, the current will be found to have different values at different points along the line. Depending on how bad the mismatch is, the current variation will be relatively small or the current variation pattern can approach the half sine wave shown. The swr on the line is defined as the ratio of the maximum current value to the minimum current value. In the case of Fig. 7(a), the ratio is 1:1 and the line is referred to as being "flat." In Fig. 7(b), if the maximum current were 3 Amperes and the minimum current 1 Ampere, the swr on the line would be 3:1.

One can actually measure the current along a line to determine swr. It is done this way in some high-power transmission lines. However, it is usually more convenient to measure voltages proportional to the value of the incident wave and to the value of the reflected wave. A directional coupler is used for this purpose, usually of the type shown in Fig. 8 (for a coaxial line). Two pickup wires are placed near the center conductor. One has a voltage inducted in proportion to the value of the incident wave, and the other a voltage proportional to the value of the reflected wave. The ratio of the two voltages is the swr, the same as the ratio of the currents previously described. As one might imagine, there is no perfect discrimination in the pickups between the incident and reflected waves. But, this type of instrument suffices for most needs. In a practical instrument, one usually "sets" the forward or incident voltage reading for full-scale deflection on a meter. Since the attenuation used remains in the circuit when the meter is switched to measure reflected voltage, the *ratio* of the two voltages is not upset. Therefore, the meter scale when reading reflected voltage can be calibrated in swr.

Since an swr greater than 1:1 indicates the load is taking less power than it could if it were matched, there is, as one might imagine, a mathematical relationship between swr and the percentage of power the load cannot accept. This formula is used to derive the "percent reflected power" one often sees marked along the swr scale on a meter.

How bad is it to have an swr of greater than unity on a line? What can one do about it? Part of the answer to the first question can be answered by going back to the simple ac circuit, and part of that answer requires a more careful look at the effects of a transmission line at radio frequencies. If the load is not matched to the line, maximum power will not be transferred to its resistive component, as in the case of the simple ac circuit. We can try to get more power out of the source (transmitter). This, of course, means loading the transmitter more heavily, with consequent heat dissipation problems, etc. But, it can be done if the transmitter can take it and if one is willing to waste input power. So, if the swr meter reads 3:1 (25% reflected power), it means that the

load could accept 25% more power if the system were matched. One could make up, approximately, for the swr by putting 25% more power into the system.

When dealing with a real transmission line, there are also a few other factors to be kept in mind, although their significance is usually a bit overstated for the normal HF installation. Any transmission line has an inherent loss due to its ohmic losses, and also rf losses, because of the dielectric material between the conductors. For instance, RG-58 coax might have a loss of about 1.2 dB for a 100-foot run on 20 meters. So, this means that even if the transmission line system were perfectly matched, a 100-Watt output from the transmitter would end up as about 78 Watts at the antenna. There is nothing that one can do about this except use a cable with a lower inherent loss at the frequency—such as RG-8. If the RG-58 line were now not "flat" but had an swr of 3:1, there would be some additional loss in this line. This is only because the reflected current wave travels along the line as well as the incident current wave. So, one suffers line losses coming and going. These losses can be obtained from a number of graphs in antenna manuals, but they are not as surprising as one might imagine. For instance, in the example given, the swr of 3:1 causes the *total* line loss to increase only to about 1.6 dB. Therefore, if we can still get 100 Watts into the line, the total loss would rise to about 31 Watts instead of the 22 Watts lost under matched conditions. Consequently, the swr has not caused any tremendous increase in the power lost in the transmission line. We are not burning up the transmission line because of the swr, but neither are we getting the available power where we would like to get it dissipated—in the antenna load. But, under some circumstances, one might accept the situation since even if a total of half the transmitter output power were not utilized due to a combination of line losses and inability of the load to accept a portion of the power, the radiated signal would only be 3 dB, or about one half an "S"-unit down. With a view toward doing something to overcome the effects of swr on a line, getting the power into the load may or may not involve doing anything about the swr. The cause of the swr on the line is the mismatch between the load and transmission line impedances. For instance, in Fig. 9(a) we have a 50-Ohm load and a 50-Ohm transmission line. No matter how long the line is, a transmitter is going to see 50 Ohms at the transmitter end of the line. In Fig.9(b), we have a complex load on the transmission line. At the junction of the line and the load there will be a mismatch. One cure for this problem is to do something at this juncture—insert an impedance matching device. This would eliminate the swr on the line, and the line would be "flat," with no more than its inherent losses.

This is usually the preferred solution, but not always a practical one. So, in lieu of this, we can tackle things from the transmitter output terminals. At this end of the transmission line there are two things we can do. One is to experiment with the length of the transmission line. A transmission line when it is not terminated in its characteristic impedance will present a complex impedance at its feed terminals. Depending on the frequency and length of the line, this complex impedance can be capacitive or inductive. So, by experimenting with the line or by doing some calculations, we can find a line length where a situation similar to Fig. 4 exists. The transmission line/load considered as a *whole* is matched. The only price we pay is the bit of increased loss on the line due to the swr. Of course, this sort of solution is only practical on one frequency. As the frequency changes, the antenna load impedance changes, the electrical length of the transmission line changes, etc. Therefore, the more common solution is to insert a tuning device at the transmitter end of the transmission line. The tuning device can handle the various complex impedances found at the end of the line on various frequencies and match the transmission line/load considered as *a whole*. It presents a constant 50-Ohm impedance to the transmitter output when properly adjusted. We haven't cured the cause of the swr, because the basic mismatch at the antenna terminals still exists. But, we will be able to get more power into the antenna and pay only a small price in terms of increased line loss due to the swr.

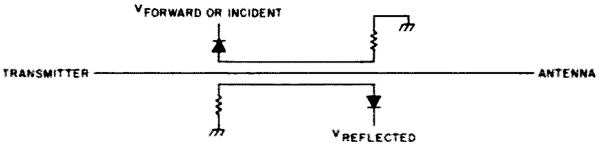

Fig. 8.

The foregoing was concerned with swr, its effects, and what may be done about it. But, to really "close the loop," we might consider if we are really getting anyplace by matching. That is, say we have the setup of Fig. 9(c). Our "super" tuning device is effective enough so that with the same antenna and transmission line on 80 through 10 meters, it presents a 50-Ohm impedance to the transmitter. The transmitter loads easily to produce a 100-Watt output, and an swr meter between the transmitter and tuner reads 1:1. The answer to whether we are getting anyplace depends upon whether we are trying to do something reasonable or not. Remember, in the discussion of the simple ac circuit it was mentioned that only resistances can dissipate power. So, if the resistance part of the antenna load is significantly higher than the rest of the resistive losses in the system (transmission line and tuner), we may be getting someplace. Most of the power will be dissipated in the higher value resistance. The resistance part of the antenna impedance is

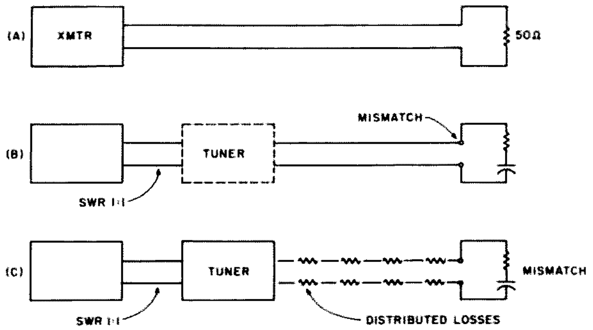

Fig. 9.

referred to as radiation resistance and can be found in antenna manuals for the usual types of antennas. For a ½λ dipole antenna, it might be on the order of 60 Ohms. So if the resistance losses in our matching system are just a few Ohms, essentially all of the power will be dissipated in the radiation resistance. Now, if we take that 10 meter ½λ dipole and try to operate it on 80 or 160 meters, the radiation resistance falls to around one Ohm or less. So, guess where all the power is going even though everything loads fine and the swr meter reading looks great? The use of tuning devices certainly has advantages in many applications. It provides more uniform loading to the transmitter across a band where the actual transmission line/antenna junction swr is changing. They also allow many amateurs to operate on bands they do not have proper antennas for by at least getting some power into the antenna for radiation. But, you can't beat the basics of power distribution in simple ac circuits, even when operating at rf!

This article has not tried to deal with every nuance of the swr question. Math has been completely avoided and a number of propositions have simply been presented without discussion, although they can be verified from antenna manuals. I feel, though, that if you try to relate the transfer of power in an rf application back, within reason, to the transfer of power in simple ac circuits, you will be able to feel more comfortable and understand more when looking at that swr meter. ■

The Active Filter Cookbook

—review of Lancaster's treatise

Canadian confirms composition's class.

Michael Black VE2BVW
16 Anwoth Road
Montreal, Quebec
Canada H3Y 2E7

In the September, 1977, issue of *73*, there was an interesting article by Peter Stark using active filters. I was glad to see this because I feel that active filters have been rather neglected. *The Active Filter Cookbook* by Don Lancaster (Howard W. Sams & Co., 240 pp., $14.95) would seem to be the next step if you liked Peter's article and want to know more.

Although not a wide variety of filters are covered in this book, everything that you need to know is here. The sort of stuff which is missing is about the more exotic types, and most people would not have any use for them. Don starts the book off with some filter basics and some definitions of filter terms. He talks about active filter advantages and disadvantages and continues with a description of the rest of the book.

In chapter two, information on op amps, which form the backbone of active filters, is given. Described are integrators, summing blocks, and basic amplifiers. Also, there are some guidelines for selecting which device is useful for your application. Finally, basic information on some of the more widely used op amps is provided.

The next six chapters give theory on how the filters work, selecting which configuration (Bessel, Butterworth, or Chebyshev) to use, and what makes up each of these three types. Information on component tolerance is given here also. Don goes on further to discuss scaling, which is an easy way of taking the normalized filters given in this book from their regular frequency of 1 kHz and placing them at the frequency which you desire.

Chapter 9 is miscellany. It gives information on selecting resistors and capacitors. It talks about manual wide-range tuning along with some thoughts on voltage control. This chapter ends with the description of elliptical filters, which are somewhat unusual.

The tenth and final chapter, like all of Don's other cookbooks, goes into some applications for active filters, such as tone decoding, modems, quadrature art, and color organs. Finally, he hints at some uses which the reader can pursue himself.

Throughout this book, math is kept simple and is used sparingly. Instead, emphasis is placed on graphs and tables, which help the reader to better visualize what is going on. Examples of selecting a filter and putting it to use are given throughout the text. There are numerous pages on active filter theory, complete with math, but this is separate from the main text and can be completely ignored by those not interested.

While some may scoff at the idea of paying so much for a book on audio filters, I would recommend this book to those who have a lot of filtering needs. At audio frequencies, active filters are far better than coil and capacitor combinations and this book will open the door to their use. ■

A Rock-Solid AFSK Oscillator

—hooray for stability!

Economy and performance go digital.

Winford Rister WB4MBL
402 Allicia Street
Albertville AL 35950

After fighting the temperature drift problem with a 555-based audio frequency shift keyer, I decided to try crystal control. The design had three basic requirements: high performance, economy, and digital circuitry.

Making a few quick calculations, I found that I could obtain a 2125 Hz tone from an 8500 kHz military surplus crystal I had on hand by dividing by 4000. Likewise, the 2295 Hz tone would require a 9180 kHz crystal. Frequency tolerance is not critical in this application because a Hertz or two off in frequency is barely noticeable (I wish some of the guys could get within 10 or so), and the crystal would have to be off 8 kHz in order for the tone to be off by 2 Hertz.

The 8500 kHz crystal I used is a small type in an HC18-type holder, which is about 1/8 by 1/2 by 5/8 inches. The 9180 kHz crystal is in an FT-243-type holder and was originally at 8970 kHz. Fortunately, this type of holder is easily opened, and, also, the crystal can be etched rather easily.[1]

Circuit Details

The circuit uses eight inexpensive ICs, all of which can be purchased from several sources for less than four dollars. Each oscillator is free running. The oscillator circuit is the simplest one available,[2] but works well for crystals in the range from about 2 to 15 MHz of almost any type. Some higher frequency crystals of the overtone type will oscillate at the fundamental frequency with this circuit.

The output of each oscillator is fed into separate divide-by-ten counters (SN7490) to ensure isolation. Referring to Fig. 1, the output of each divider, now 850 and 918 kHz, respectively, is fed into a NAND gate, U7A-U7D (SN7400). The four gates in this chip are wired so that only one of the frequencies is passed at a time, depending upon whether the switching input is low or high. The signal is taken from the last section of the 7400 and divided by 10 twice more with U3 and U4 and then divided by 2 twice by U8, the SN7473 dual flip-flop. This results in a total division by 4000, which yields square waves of 2125 and 2295 Hz. The signal must consequently be passed through a low-pass filter in order to change it to a sine wave. I used a circuit similar to that in the AK-1[3] for the filter. Active low-pass filters could be designed for this job, but the main advantage to them is space savings, since no amplification is needed. The passive filter won out in my case for simplicity and eliminated the need for another power supply connection on the board. Some adjustment in the divider network may be necessary to suit individual transmitter requirements. Finally, this sine wave is fed into the microphone input of an SSB transmitter.

The keying circuit shown is designed to operate from the series loop in the printer and keyboard. The keying input is taken from the top of the emitter resistor of the loop switching transistor (27-Ohm resistor in my TU). If plus 5 volts is used for the switching input, resistor Rs should be increased to 15k Ohms. If separate keyboard and printer circuits are used, the input should be modified accordingly. If it's more convenient to have the mark condition low instead of high, the two crystals could be switched or another transistor configuration could

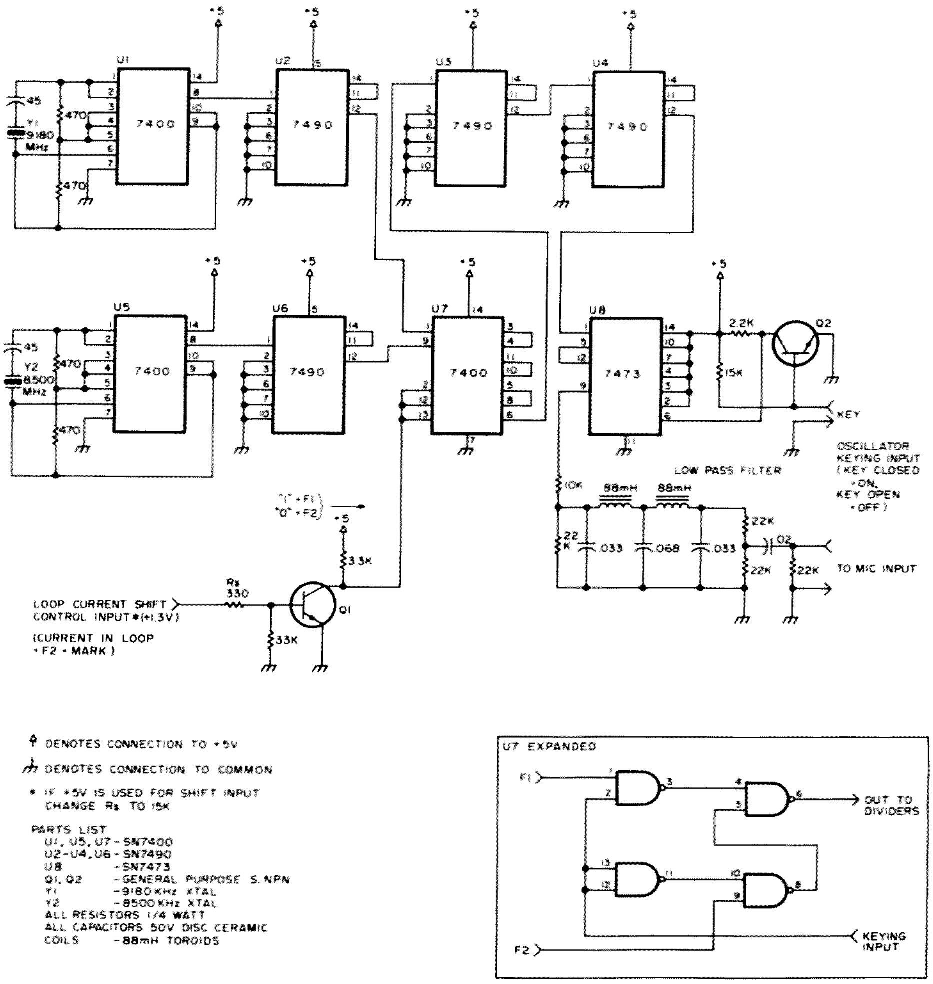

Fig. 1. TTL crystal AFSK oscillator.

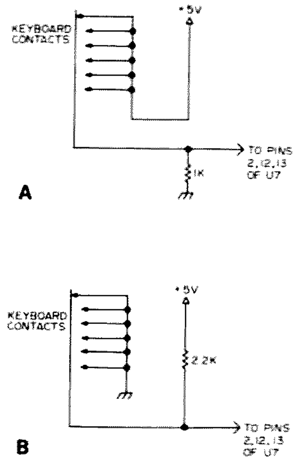

Fig. 2.(a) Separate keyboard normally high; (b) separate keyboard normally low (requires reversing crystals).

be used (see Fig. 2). For CW ID, on-off keying is used instead of narrow shift. The key thus also acts as a transmit-receive switch when using VOX with the transmitter.

Construction Details

The complete circuit, except for the power supply and the 88 mH toroids, is on a 2- by 4-inch circuit board using the layout shown in Fig. 3. Bypassing of all plus 5-volt leads with a .1 uF capacitor is recommended. Leads should be kept as short as possible, and all leads which leave the chassis should be bypassed to ground to prevent rf from activating the switching chip. Good filtering of the power supply is necessary for a clean output from the transmitter. The circuit draws about 180 mA.

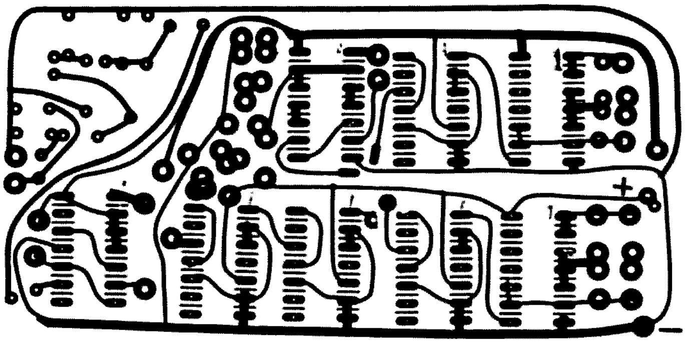

Fig. 3. PC board layout, foil side.

Conclusion

While not having the advantages of a single crystal synthesized unit, this one does have rock-solid stability, is relatively inexpensive, and is readily compatible with computer or TTL circuits. Several QSOs were made using this unit, and only favorable comments have been received.

Acknowledgements

I wish to express thanks to all the authors mentioned in the references and many others from whom I got ideas and circuit information before deciding to design and build this circuit. Also, I am grateful for much assistance from Jimmie Straughn K4COV who did the layout and helped with making the board.

I will be glad to answer any questions of design, availability, performance, etc., if inquiries are accompanied by an SASE.■

Pulser Plus

—a one-shot with more

This circuitry turns your single-shot multivibrator into a useful piece of test equipment.

This gadget is a combination of circuits from two previous articles. The first, in the October, 1974, issue of *73*,[1] described a wide-range repeating pulse generator using three 555s. The second article was in *73* for February, 1975,[2] and described a variable pulse width, single-shot generator using TTL devices. Both of these circuits were interesting and I hope that the circuit discussed here has kept all the good features of both.

The circuit of the pulser is shown in Fig. 1. Here, again, the circuit consists mainly of three 555s. Every time S1 is pressed, there is a pulse at the output, the length of which is variable over a wide range. Both positive- and negative-going pulses are available. The unit operates over a supply voltage range of 4.5 to 16 volts, which makes it usable with both TTL and CMOS, and even linear circuitry under certain conditions.

Here's how it works: U1 is connected as an RS flip-flop. I have not seen much on using the 555 in this way, but it is just right for our application. As long as pin 2 is low, the output is high. When S1 is pressed, pin 2 goes high, pin 4 goes low, and the output (pin 3) goes low. Since a 555 is negative-edge triggered, U2 will be triggered when pin 3 of U1 goes low. As U2 is connected as a single-shot multivibrator, there will be a pulse on pin 3 for a length of time determined by the equation $T = 1.1(R1 + R2)C1$. A positive-going pulse is available from pin 3 of U2. U3, connected as an inverter, provides a negative-going pulse. Note that the output pulse is somewhat less than the supply voltage and the pulse height varies directly with this voltage.

An interesting addition to this circuit is also shown in Fig. 1. This is nothing more than a diode bridge, but, when hooked up as shown, it allows you to get power from the circuit that you are testing without worrying about connecting the polarity wrong. This trick is not new, but it is a great addition to simple pieces of test equipment like this pulser and logic probes.

This circuit can easily be built using a minibox as an enclosure. Have R1, S2, and S1 mounted on the front. Put J1 in the back. Perhaps a rough calibration of R1 would be useful. In some applications, both output polarities may be required, in which case S2, the polarity selector, could be eliminated, and two output jacks used. Be sure to locate S1 so that it can be used without hitting any of the other controls.

This unit can be used anywhere that a variable width, single-pulse multivibrator is needed. While it is not very different from the average one-shot, the little extras make it a valuable addition to your lab. ■

Oh, My Poor Quad!

— measuring wind speed

L'Eggs are the legs.

Several *73 Magazine* articles on anemometers and weather indicating devices by W2AOO[1,2] and W9CGI[3] caught my interest and led to the construction of the anemometer shown in Photo A. I have been casually interested in wind speed and direction, particularly when going fishing or sailing or attempting to outguess the weatherman.

Several early construction attempts were unsuccessful due to the lack of a readily available, low-cost pivot point, and a method of trapping the wind (cutting Ping-Pong™ balls in half just didn't work).

After stacking a three-element 15 meter beam and a three-element 20 meter beam, I became even more interested in wind direction and wind speed. The wind surface area and resultant torque vary considerably depending on whether the wind blows against the elements broadside or against the boom length (element tips facing the observer). In my instance, the antenna surface area is approximately 9.5 square feet when viewed broadside and less than 5 square feet when facing the boom lengths. When you consider the combined antenna torque and wind loading on the antenna and tower, the resultant load on the rotor and tower is considerable.

Pointing the antenna boom lengths into the wind significantly reduces the wind loading and lengthens rotor life. If high winds should develop, an indicating device in a high-traffic area such as the kitchen would indicate wind speed and gusts. A wind vane mounted on the tower would serve to indicate the wind direction.

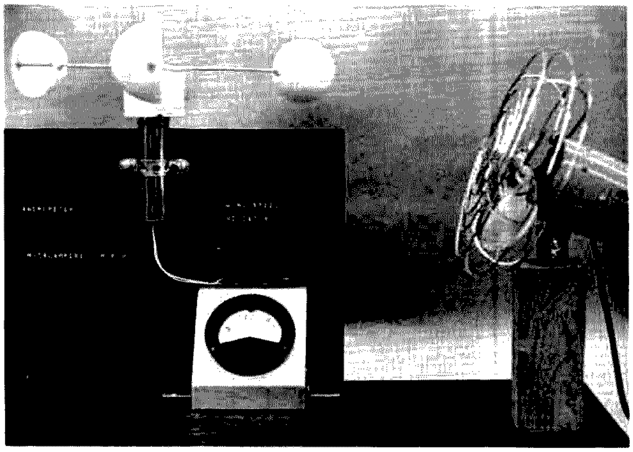

Photo A. *Complete anemometer system.*

The major items required to construct the anemometer are a bicycle front axle, three L'Eggs™ stocking containers, a slot-car motor or other permanent magnet dc motor (which will serve as a dc generator), a 0-50 microampere meter, a pipe or length of tubing, and the top from a spray paint can (Photo B).

The problem of finding a low resistance pivot point was solved by cutting in half the front axle of a discarded bicycle and using it as the pivot point. Most bicycle axles may have to be annealed before drilling a hole to accept the motor shaft. This shaft can be held in place with epoxy glue or setscrews (Photo C). I used setscrews to secure the motor shaft to the axle so that the motor could easily be changed, although this hasn't been necessary during two years of operation. Be sure the slot-car motor readily drives the 0-50 microampere meter when spun by hand.

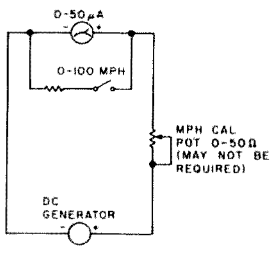

Fig. 1. Anemometer schematic.

A piece of tubing or pipe is selected so that the lip of the bicycle axle rests on the outside diameter of the tubing as shown in Photo D. An aluminum retainer bracket secures the axle to the tubing, and a piece of Romex insulation taped around the dc generator will prevent it from rotating inside the tubing.

In Photo E, three 1/8-inch diameter aluminum rods are cut into 7¼-inch lengths and threaded. The L'Eggs stocking containers are secured with nuts. Each rod is then threaded into a 1¼-inch diameter by ¼-inch thick aluminum disk. The threaded holes are spaced 120 degrees apart. The center of the disk should be drilled so that it will pass through the bicycle axle.

Locate a plastic aerosol spray can top which will be used as a rain shield. Cut, or burn out with a soldering iron, the internal

Photo B. Component parts of anemometer.

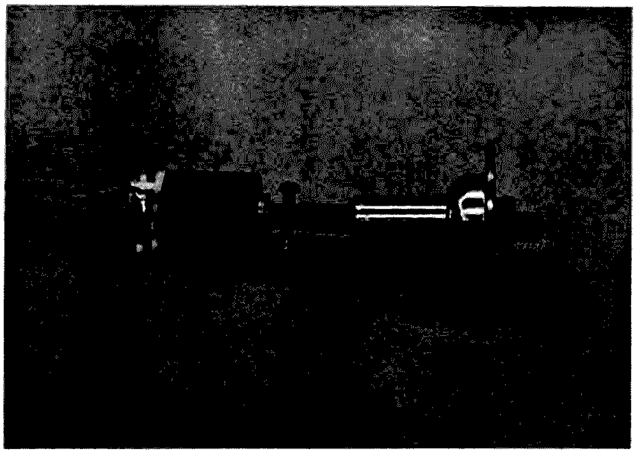

Photo C. Slot-car motor attached to bicycle axle by means of two setscrews.

plastic wall which is used to lock the cap on the can. A hole should be drilled in the center of the cap so that it will fit over the axle. The unit is assembled by placing the cap over the bicycle bearing nut, followed by the cup assembly (which is secured with the remaining axle nut). (Photo E.) A wooden plug may be inserted in the other end where the two wires come through.

It just so happened that three of the constructed anemometers indicated approximately one microampere per mph on the 0-50 microampere meter readout device. Depending on various motor/dc generator outputs, a small value of variable resistance (0-50 Ohms) may have to be inserted in series to calibrate the mph reading. A switchable shunt resistor should be installed across the meter movement. This will enable the meter to read 0-50 mph or 0-100 mph full scale. Refer to Fig. 1.

The internal resistance of the meter and the shunt value can easily be determined by using the formula or circuits found in the *ARRL Handbook*. In most cases, the shunt value will be the same as the meter's internal resistance. A typical shunt value would be 5 Ohms. I used common carbon resistors since extreme accuracy was not as important as the relative readings.

Frequent monitoring of a NOAA weather station indicated that the observed meter measurements were very close to local mph readings. Since I was only concerned with relative readings, no actual calibrating resistance was required.

If you are a purist, the easiest way to calibrate the anemometer is to compare the readings with an anemometer of known accuracy. An alternate method would be to mount the anemometer on the front of a car and adjust the calibration pot. An open field or vacant parking lot should be selected and all safety precautions and speed limits observed. A 10 mph reading should be sufficient for adequate calibration. The air-foiling effect of the car chassis will affect the readings if it is held outside a window. Also, be sure the wind is not blowing.

One word of caution: Provide some means of disconnecting and grounding the lead-in wire from the anemometer to prevent damage from lightning.

Mount the anemometer in a clear, unobstructed area and pay attention to Mother Nature! ■

A Self-Contained, Fully-Automated, Transistorized Fuse Tester

—amaze your friends

Take a look at the English answer to the battery and bulb.

C.F.J. Ward G3TAI
50 Lakeside
Bracknell, Berkshire
England RG12 2LE

Here is a simple fuse tester for the shack which is quick and easy to build and use. Although it is only one step better than a battery and bulb, it does have an advantage in that it will test those low-current fuses that appear here and there. (And it is bound to impress your nontechnical friends!)

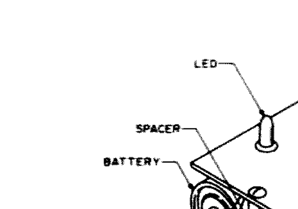

Fig. 1.

The circuit is shown in Fig. 1, and operation is as follows:

1. With no fuse connected, there is no base current and, hence, no collector current; the LED remains dark. Use of a silicon transistor ensures that the leakage current is negligible.

2. When a short circuit (good fuse) is placed across the test terminals, it completes the base drive line, and base current will flow. The resulting collector current will light the LED.

The base current will have a value of approximately 0.24 mA since the supply is 3 volts. The base-emitter drop is about 0.6 volts, and the base drive resistor is 10k Ohms. This will cause a collector current of HFE times 0.24 mA to flow, and, for a typical HFE spread of 50 to 150, this will be 12 to 36 mA, which will easily light the LED. With my unit, I used a low-gain transistor salvaged from a surplus computer board which gives a collector current of 16 mA. With a high-gain transistor, the collector current can be adjusted by increasing the value of the base drive resistor, but it is much better to use a low-gain transistor because leakage current through the fingers when using the tester can cause the LED to light even if the fuse is blown! This effect is much worse with high-gain transistors.

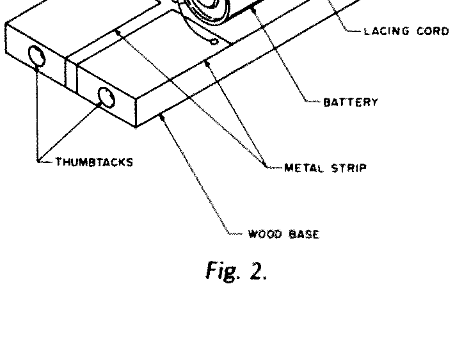

Fig. 2.

Construction

The tester can be made up as shown in Fig. 2. The components are mounted on a small piece of Veroboard. This is fixed to the wooden base plate with screws and spacers made from ball-point pen cases cut into ¼-inch-long tubes. The two AA-size batteries are tied together with lacing cord, which holds them against the spacers. The test terminals are made from some brass strip that I had in the junk box, but bits cut from an old can would do as well. The batteries are soldered into the circuit since no current flows unless a good fuse is tested. They should last a long time with the intermittent use expected of a fuse tester.

I have drilled a hole in the base of my tester so that it can be hung up when not in use. ■

Don't Get Burgled!

—build this simple alarm

Isn't security worth $10 or less?

William R. Fletcher, Jr.
2810 Riverview Drive
Fairbanks AK 99701

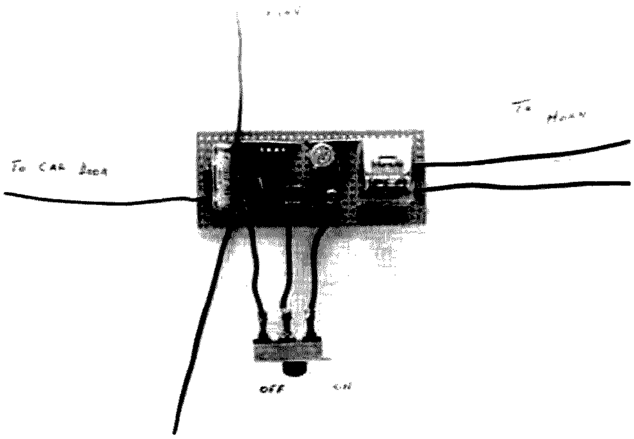
Here is a simple burglar alarm that makes an excellent one-evening project and can result in a safe car or shack. It is based on the fact that some thieves will not stop for anything except a good reliable alarm such as this one. There are no critical parts to find or adjustments to make with this alarm as with others I've seen (Jeffrey Pawlan WA6KBL, "The Smart Alarm," *73 Magazine*, June, 1975). The circuit allows safe exit and entry using a minimum of components. Most ham operators with a small junk box could probably build it for almost nothing. Even if you had to buy all the parts new, it should cost less than $10. Shopping in the back of *73 Magazine* could put it closer to $5. Not much for such a reliable source of protection.

Operational Description

All you have to do is park your car, open the door, set the alarm, and exit. Unlike other alarms I have read about, there is no minimum exit time on this one. For example, you can take as long as you want to unload groceries, kids, etc. This alarm is only activated and starts timing out the next time your door is opened, such as when you return or when a thief decides your car is next. You then have ten seconds to switch off the alarm. Once switched off, it will not sound the car horn.

Circuit Description

The circuit is inexpensive, reliable, and very easy to build. For active com-



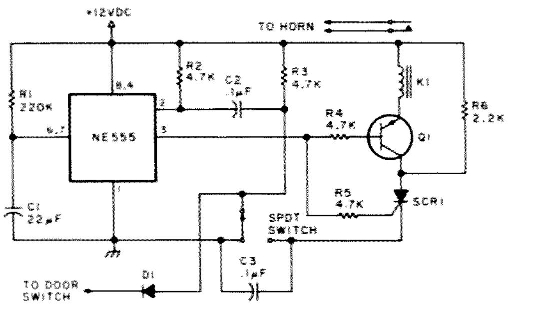


Fig. 1. Burglar alarm schematic diagram.

ponents, it uses a very common integrated circuit (NE555), one PNP transistor, and one SCR. See Fig. 1.

The timer circuit is designed to have 12 V dc applied at all times. If the circuit used a power switch, it would cause false triggering of the timer, and this would cause the horn to sound after time-out. It does, however, use a switch in the relay circuit. With the switch in the off position, it holds the input to pin 2 at ground, which also prevents false triggering of the timer. With the switch in the on position, it puts ground to the relay circuit so it can be switched in or out, to shut off the alarm, and removes the ground from the trigger input (pin 2). When pin 2 goes high (12 V dc), this arms the alarm.

When you open the door, the switch is in the off position and ground is applied to the trigger input (pin 2). If the door opens, the door switch puts ground on the trigger input wire. Now you can switch to the on position. This arms the circuit and the trigger input still sees ground (via the door switch). You can now close the door and lock it if you wish. This puts pin 2 at 12 V dc. The next time the door is opened, pin 2 receives a negative-going pulse which starts the time-out. When pin 2 goes low, pin 3 (output) goes high (12 V dc) and turns on the SCR. After the circuit times out, pin 3 drops back low again, which turns on Q1, and K1 energizes which sounds the alarm. Relay K1 can be connected to a horn, bell, lights, or any combination thereof. The alarm will continue to sound until you shut off the switch and, by then, the would-be thief should be long gone.

If for any reason you need to alter the entry time, it is easily accomplished by changing R1 or C1. Increasing either will lengthen entry time and decreasing either will decrease entry time. With the components shown, entry time is about 10 seconds. I find this to be just about right to comfortably enter and shut the alarm off.

If this alarm is to be used for shack protection, you must build an additional input circuit which is nothing more than a switch and resistor combination (Fig. 2). Also, if house current is preferred over a battery, Fig. 3 shows a power supply circuit that will work.

This alarm has already proven itself once for me! Since that one attempt on my car by a thief, I consider it to have paid for itself. If you value your possessions as I do, this alarm will give you peace of mind while away from your car or shack. ■

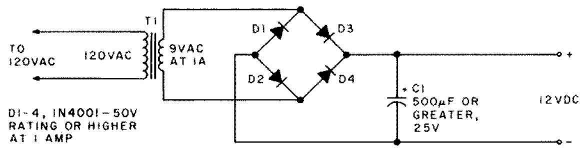

Fig. 3. Power supply schematic for burglar alarm.

Power x 2

—dual auto batteries

Your car will always start, and you can operate all you like.

Harry J. Miller
991 42nd Street
Sarasota FL 33580

If you'd like to install a second battery in your car to operate your radio, CB unit, ham setup, etc., and not worry about having enough current to operate your starter, use the device shown in Fig. 1.

Your car's alternator will charge both batteries, but operating your radio gear too long will only discharge one, leaving the regular vehicle battery fully charged for instant use.

D1 through D4 are stud-mounted silicon diodes rated at 60 piv and 25 Amps or more. Mount with the usual insulating washers on a heat sink. ■

Experimenting with Tones

—fun with functions

Tone generation the foolproof way.

Tone generators, or audio oscillators as they are commonly called, are frequently used in amateur and commercial radio systems. They are used in touchtone™ pads, toneburst generators, subaudible generators, AFSK oscillators, and in remote station control systems. They have also been widely used for years in test generators for testing AM, SSB, and telephone equipment. While there are many ways to generate tones for these and other uses, most of the traditional methods have drawbacks of one sort or another. LC circuit oscillators, for example, are difficult to tune up, twin-T oscillators sometimes are reluctant to oscillate, and multivibrators aren't always as stable as required. The above problems are compounded when attempting to adapt these oscillators to frequency shift keying. While these drawbacks aren't too serious to an experienced experimenter or engineer, they sometimes prove to be major frustrations and obstacles to the average experimenter who needs a good audio oscillator quickly.

An easy and almost foolproof way to generate audio tones for a large variety of purposes is to use one of the IC function generators, readily available from most electronic supply houses. These function generators and a minimum number of external components will provide stable, low-distortion sine wave audio outputs. This article describes the operation and application of these IC function generators, and gives simple examples and circuits using an EXAR XR2206 function generator IC. The experiments require no test equipment other than a pair of earphones and a VOM. The total cost of these experiments should be under $10, provided that a source of 12V dc is available.

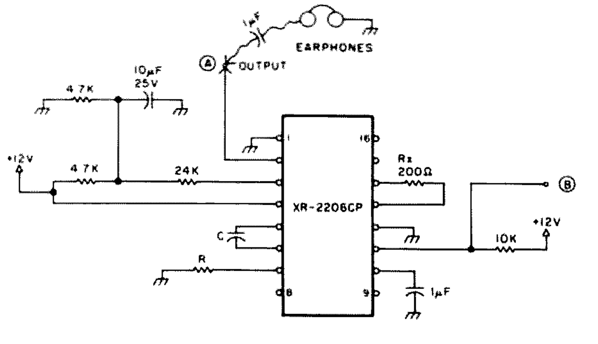

Fig. 1. Basic audio oscillator. All resistors are 1/4- or 1/8-Watt. For a frequency of 1 kHz, C = .1 uF, R = 10k.

The EXAR XR2206 IC Function Generator

Fig. 1 shows a basic audio oscillator using an XR2206 IC. None of the components is critical, and the circuit should work the first time it is turned on. R and C are the frequency determining components. With the values given for R and C, the function generator will produce an audio output of 1 kHz. Connect the earphones to point A through a .1-uF capacitor as shown. A clean sine wave of about 1 kHz will be heard. The output impedance is 600 Ohms, and the IC will drive earphones of 600 Ohms or higher impedance. It will not drive a 4- or 8-Ohm speaker. The rms audio output is about 1-2 V, which is more than enough for most purposes. For ease of construction, the circuit may be breadboarded on a Continental Specialties or similar breadboard.

With the earphones still connected to point A, remove Rx from the circuit. The output should become slightly richer in harmonics as the sine wave is changed to a triangle wave. If an oscilloscope is available, the waveforms should appear as shown in Fig. 2.

Connect the earphones to point B, the square wave output, through a .1-uF capacitor. A 1-kHz tone, rich in harmonics (square waves), should be heard. If an oscilloscope is available, the waveform should appear as shown in Fig. 3.

The output frequency of the function generator is determined by R and C, by the expression:

$$f = 1/RC.$$

Thus, in this case,

$$f = 1/[(1 \times 10^4)(1 \times 10^{-7})] = 1/10^{-3} = 10^3/1 = 1000 \text{ Hz}$$

Component tolerances are an important consideration if a precise frequency is desired. With average, run-of-the-mill

capacitors and resistors (20% tolerances), you can get near the desired frequency, but you won't get exactly on frequency. If a precise frequency is desired, then a trimming resistor should be inserted in the circuit as shown in Fig. 4.

Temperature Stability

The temperature stability of the XR2206 is about 15 parts per million per degree centigrade, or about .15% over the temperature range of 0 to 75 degrees C. This is very good temperature stability and probably better than needed for most purposes. Unfortunately, in practice, it is difficult to achieve this stability due to temperature tolerances of R and C, the frequency determining components. In the circuit given in Fig. 1, it is assumed that normal run-of-the-mill carbon composition resistors and disk ceramic capacitors will be used. Components of this variety exhibit very poor temperature stability, and will change in value from 10 to 20% from room temperature to freezing. This phenomenon can be verified by connecting the output of the tone generator to a counter, and then placing the tone generator in the refrigerator. A significant change in frequency will be noted.

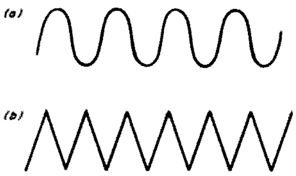

Fig. 2. (a) Waveform with Rx in circuit; (b) Waveform with Rx removed from circuit.

Fig. 3. Waveform at square wave output.

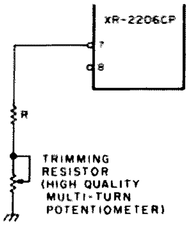

Fig. 4. Adding a trimming resistor to adjust frequency.

The temperature stability of the tone generator circuit can be improved considerably by using temperature-stable components for R and C. For C, mylar™ or silver mica capacitors should be used; for R, 1% resistors of the variety RN55 (an industry designation) should be used. These components exhibit good temperature stability, and are readily available from the supply houses listed at the end of the article. Fig. 5 shows a stable oscillator with a table of components for various frequency ranges.

The XR2206 IC is a unique chip in that it is designed for two-frequency or AFSK operation. If the circuit in Fig. 6 is used, the frequency will change from 1000 to 1170 by grounding pin 9. By adding a relay, as shown in Fig. 6, this circuit may be used for AFSK keying. The output of the oscillator is continuous when changing frequency, as shown in Fig. 7, and thus the oscillator may be used to modulate an SSB transmitter to produce FSK.

Tone-Burst Oscillator

Fig. 8 shows a simple tone-burst oscillator. Point C is connected to the push-to-talk line in the transmitter. When the transmitter is keyed, a short tone burst is generated and fed to the audio circuit of the transmitter. R_T adjusts the time duration of the tone burst, and R_A controls the output tone level. Choose C and R according to the formula shown for the desired frequency.

Subaudible Oscillator

A simple subaudible tone oscillator may be constructed by using the circuit in Fig. 8. In this case, omit the NE555V and its associated components, and connect pin 4 of the XR2206 to +12 V. The output of the subaudible generator should be connected to the high side of the modulation or deviation control in order to bypass audio speech filters that pass speech in the 300-3000-Hz range. This type of oscillator is called

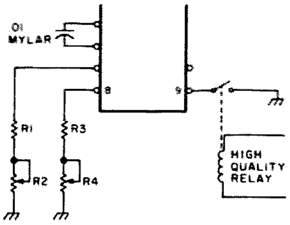

Fig. 6. AFSK oscillator. R1 = 90,900 RN55, 1%; R3 = 75,000 RN55, 1%; R2, R4 = multiturn miniature 20k pot, such as Beckman or Spectrol, which are used to trim the frequencies to 1000 Hz and 1170. Hz, respectively.

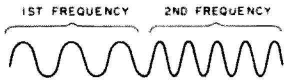

Fig. 7. Oscillator output when changing frequency.

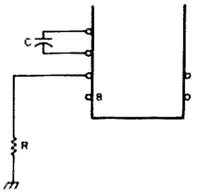

Frequency	C	R
100 Hz	.01 mylar	1 meg
500 Hz	100 W V dc	200,000
1000 Hz		100,000
1500 Hz		66,500
2000 Hz		49,900
3000 Hz		33,200
5000 Hz		20,000

Fig. 5. Stable oscillator. Resistors are 1% tolerance MIL style, RN55D, RN55C, or RN55E. f = 1/RC.

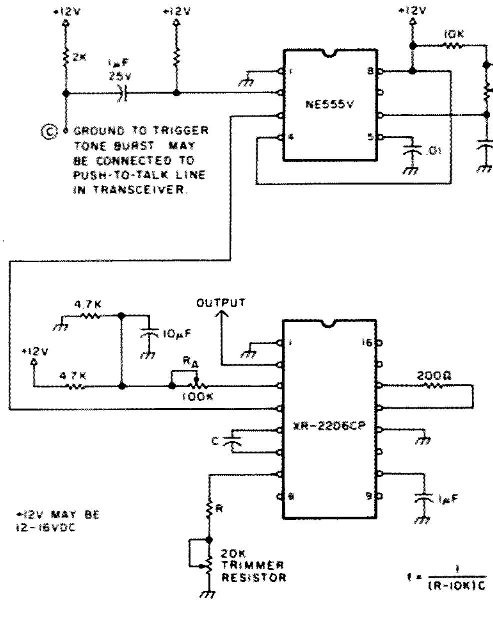

Fig. 8. Tone-burst oscillator.

subaudible since FM receivers with private line or tone squelch capability filter out frequencies below 300 Hz, and are not passed to the audio stages. Subaudible frequencies (frequencies below 300 Hz) are used to activate a private-access repeater or station.

Audio Test Generator/ Code-Practice Oscillator

A simple audio test generator may be constructed by using the circuit in Fig. 4. If R is 10k and the potentiometer is a 500k pot, the frequency may be varied over the range of about 200 Hz to 10 kHz. This simple generator may also be used as a code-practice oscillator by placing a key between +12 V and pin 4 of the XR2206.

Other Function Generators

The circuits given in this article were based on the XR2206, which was chosen because of its ease of use and availability. Other function generators, such as the XR2207 and the Intersil 8038, may also be used to generate audio frequencies. However, they are not the same as the XR2206 and lack some of its capabilities. If these other chips are to be used, a set of application notes should be obtained from your distributor. ■

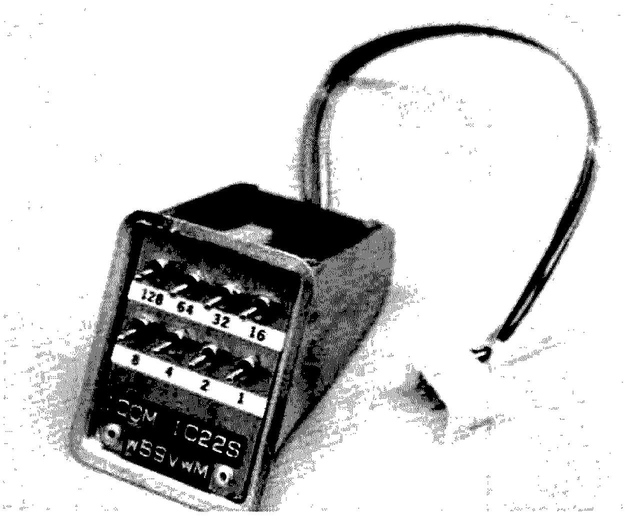
—article for non-smokers

Let your dashboard do it for the 22S.

Hugh S. Pearl WB9VWM
2502 Oak Lane
Rolling Meadows IL 60008

Being a non-smoker and the owner of an Icom IC-22S provided me with a simple way to have a programmer built permanently into my car. The cup in the front ashtray is removable and has enough room in it for 8 miniature toggle switches and 8 diodes needed to program the 22S for any of its frequencies.



An aluminum plate was cut to fit the ashtray opening and drilled out for the switches and mounting holes. The back of the ashtray has a hole and rubber grommet in it to protect the connecting cable. A 9-conductor ribbon cable (10 conductor with one wire removed) was used with the accessory plug connected to one end. The photo shows a 24-pin Molex plug which my rig uses, but the 9-pin plug Icom provided works just as well. The switches, diodes, and ribbon cable were obtained from James Electronics.

I made a listing of the frequency conversion code and mounted it to my visor. When the ashtray cover is closed, the programmer is hidden in the dashboard. Best of all, now no one leaves old butts in my ashtray.

The connector in the radio is connected by the ribbon cable to the channel 22 switch position on the matrix board. The other 21 positions can be permanently programmed as you desire. ■

Attention, Satellite Watchers!

—a solid-state monitor for GOES

The satellite doctor strikes again.

In a previous article in *73* (November, 1978), I described various approaches for reception of GOES (geostationary operational meteorological satellite) picture signals on S-band (1691 MHz). For the experienced satellite fanatic, the S-band conversion is the big snag to implementing GOES operations, since most have adequate display equipment to handle the APT mode pictures. For newcomers, however, the problem is more complex, particularly since many new converts to weather satellites have little experience in electronic construction. All things considered, the easiest approach for most is an integrated display monitor which permits photographs to be obtained from a TV-like display.

Photo A. The remote display terminal in the author's prototype. This used the cabinet, bezel, CRT, HV module, and yoke from a Robot fast-scan viewfinder. The cabinet contains these components and the relevant CRT circuits.

The *73 Weather Satellite Handbook* contains one such display unit that will do a fine job. This monitor is a multimode unit, however, and is designed to handle both geostationary and polar orbiting satellites. If geostationary spacecraft such as GOES are the major objective, there are several design simplifications which are possible. In addition, since designing the original unit, several new circuit ideas have been tried with good results. It seemed a good idea to present a circuit incorporating many of these ideas while, at the same time, getting at a unit that was designed strictly with GOES service in mind.

Before getting into a discussion of the unit, a short digression on design philosophy is in order. There is no single-circuit solution to any given problem. Some approaches are more complex than others, and each has its own unique tradeoff between simplicity and performance. As is always the case in my published circuits, I have taken the simplest approach that will yield quality results. If you think you have a better solution at one point or the other, feel free to modify the beast. If worse comes to worst, you can always put it back in its original state with assurance that it will do a good job.

The second problem facing the home constructor these days is the matter of obtaining parts. It gets hard enough to obtain garden-variety components at times, without trying to duplicate a circuit where the author had access to a one-of-a-kind part left over from the construction of the last lunar module! In that regard,

you can rest assured that all of the parts specified are widely available and a wide margin for substitution exists. In each case where this is possible, I will try to outline what you should look for in substitute parts. Virtually all of the specified components are available from local distributors, off the pegboard at your local Radio Shack, or from mail-order supply firms.

Finally, as an aid to those who are terrified of what looks like a complex project, virtually all of the active circuits for this monitor have been boiled down to single large plug-in circuit boards with only 14 connections to the outside world. For those without facilities for making PC boards, the boards are available, as I will note later.

Circuit Functions

In the broadest sense, the monitor has to take the satellite video signal and turn it into a meaningful image. To understand how it does this, we must first understand the satellite video format which is summarized in Fig. 1. GOES pictures are transmitted in the APT (automatic picture transmission) mode, and, for the sake of discussion, the overall circuit can be broken down into a number of fundamental subunits, each with its own function.

(1) Video circuits—These circuits must filter the signal to remove any components outside of the video passband and must demodulate it in such a way that maximum subcarrier amplitude (white) results in a bright trace on the screen, while minimal amplitude (black) causes the trace to be extinguished.

(2) Sync Circuits—Here we must maintain a precise 4 Hz trigger rate in order to display the picture properly. Since it is possible to record the satellite pictures on standard audio tape, it is most useful if the sync circuits will function even with the speed variations resulting from the recording and playback process, in addition to handling satellite signals in real time.

(3) Phase circuits—Although the sync circuits maintain the proper trigger rate, they cannot assure that the line trigger pulse that starts each display line corresponds precisely with the start of each line of satellite video. Without special provisions for phasing the picture, you are likely to get a display where the left edge of the actual picture falls somewhere inside the display frame, forcing you to cut and paste the picture to get the proper display.

(4) Horizontal deflection circuits—In this case, we want to generate a linear, 250 ms line each time a line trigger pulse is produced by the sync circuits.

(5) Vertical deflection circuits—Here we want to produce a linear vertical scan which requires 200 seconds for the trace to move from the top to the bottom of the screen. If 8-second frames in slow scan (SSTV) are actually slow scan, then APT pictures with their 200-second frame intervals are very slow scan indeed!

The remaining functional description will center around Fig. 2 (a system block diagram) and the schematics in Figs. 3-8.

Subcarrier frequency	2400 Hz
Subcarrier modulation	FM
White level	maximum amplitude (@ 96%)
Black level	minimum amplitude (@ 4%)
Dynamic range	@ 14 dB
Line rate	4 Hz (240 lines/min.)
Direction of horizontal scan	left to right
Frame rate	200 seconds
Direction of vertical scan	top to bottom
Number of scanning lines/frame	800
Aspect ratio	1:1 (square)
Baseband video bandwidth	1600 Hz

Fig. 1. Characteristics of the APT satellite video format.

Video circuits (Fig. 3). The video signal from the receiver or tape recorder enters the unit at J1 across the 10k CONTRAST control (Fig. 7). Since the gain of all circuits after the CONTRAST control is fixed, it is this control that determines the amplitude of the final processed signal and, hence, the contrast of the displayed pictures. From the CONTRAST control, the signal enters the main circuit board on pin 12 (Fig. 3) where it passes through an active filter (U1) set up for a center frequency of 2400 Hz, a bandwidth of 1600 Hz, and unity gain. The 2840-Ohm resistor in the input circuit sets the center frequency, and can be approximated closely enough by paralleling two 5600-Ohm resistors. From the filter, the signal is routed to U2, which is the video power amplifier. Here the signal gets a significant power boost. A part of the subcarrier signal is tapped off at "A" for the sync circuits which will be described shortly. The signal is also routed off the board at pin 15, where it goes to T1 to be stepped up in voltage in the high impedance secondary windings. Here it is detected by a bridge rectifier network. The output of the detector is a 4800 Hz waveform (positive going) whose amplitude is proportional to the instantaneous amplitude of the satellite subcarrier. This signal is applied to the CRT grid across a 10k load resistor (Fig. 7).

The CRT is biased by the BRIGHTNESS control in the cathode circuit so that the tube is just cut off (the trace is just extinguished when viewed in a dark room). Any positive excursions at the grid will cause the trace to brighten proportionally to the applied voltage which is precisely what APT display requires. About 5 V swing on the grid is all that is required for useful display. To prevent transients or other inputs from blooming the trace, a conventional silicon diode and zener are used across the grid resistor to provide peak white limiting by holding voltage at the grid to a maximum of a little over 5 V. Q1, the blanking transistor, is driven by the line trigger pulse, pulling the grid to near ground potential and blanking the trace during horizontal retrace.

Sync circuits (Fig. 4). The operation of the sync circuits is based on the fact that the 2400 Hz satellite subcarrier is locked to the same master frequency source as the 4 Hz line trigger generator. If we can lock a stable frequency source to the subcarrier signal, it is possible to derive the 4 Hz line trigger rate by digital frequency division. Our reference source in this case is a 565 phase locked loop. The internal voltage controlled oscillator (vco) of the loop is adjusted to free run very close to 2400 Hz by the 1k vco pot. When a sample of the subcarrier signal from "A" is applied to one input of the phase comparator, the vco is pulled onto the subcarrier frequency with the vco output providing a stable source for frequency division. The loop will follow any reasonable frequency changes caused by speed changes in the tape recorder, thus providing

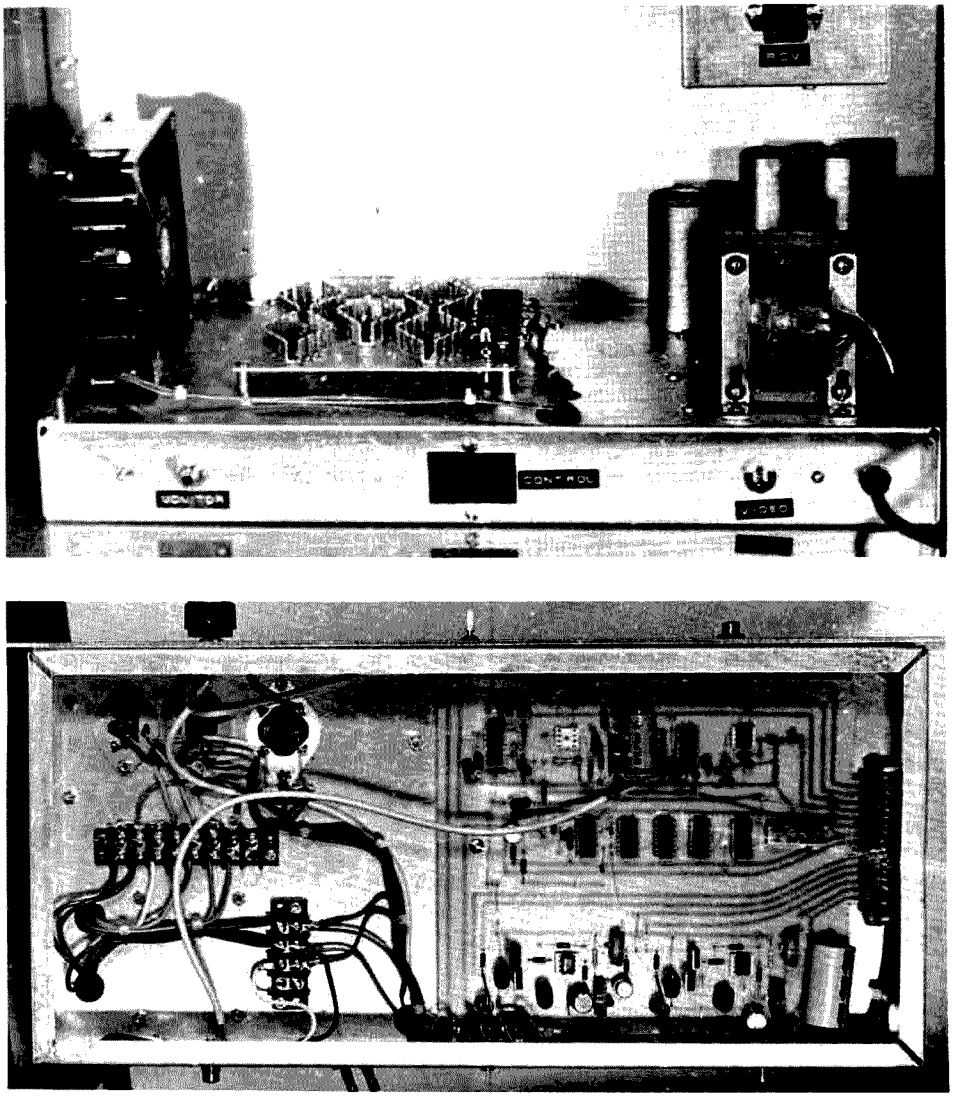

Photo B. Above chassis (top) and below chassis (bottom) views of the electronics assembly of the author's prototype. This unit contains the power supply and the main circuit board. A fan was required to compensate for inadequate heat sinking of the regulators (see text).

for display of recorded video as well. The vco signal from the PLL (U3) is routed through a series of gates in U4 to provide phasing, a function I will discuss shortly. The 2400 Hz output from U4 is then routed to a frequency divider chain composed of U5, U6, and U7, providing a total frequency division of 600. Since 2400/600 = 4, we have derived the proper line trigger rate. This 4 Hz signal is routed to a 12 ms single-shot (U8) which generates the required trigger pulse. A sample of this pulse is routed to board pin 10 for blanking, while another sample, "B", is used to actually trigger the horizontal deflection system.

Phase circuits (Fig. 4). Although the phase locked sync system does maintain the proper line rate, it cannot assure that the line triggering in the display coincides with the start of a line of video data. When it does not, which is likely to be the case most of the time, you get a situation where the left edge of the satellite picture is actually inside the frame. This condition is corrected by the phase circuits. To understand their function, it is necessary to redraw a portion of Fig. 4 to show the connections of the various gates. This is done in Fig. 4(a).

The PHASE switch, a normally-closed pushbutton, has one side grounded and the other connected to the phasing bus on the main board at pin 8. Since the phase bus is normally grounded, this low is inverted to a high by gate D, and this high is applied to one input of gate B with the other input to the 2400 Hz PLL signal that is buffered by gate A. The 2400 Hz signal is thus gated through gate B and then through C without interruption on its way to the sync divider chain. When a phase error exists, however, the switch is pressed (opened), and the status of the phase bus is now determined by the state of the collector of the phasing transistor (Q2). This transistor is driven by the $\overline{Q}$ output of U8, which is high except during the 12 ms trigger interval when it goes low. This results in the collector of Q2 remaining low except for a 12 ms high that is coincident with the trigger pulse. This high is inverted to a low by gate D, and this low at one input of gate B stops the 2400 Hz signal for 12 ms. This interruption, occurring once each line, represents a 12 ms counting error in the sync chain so that the next trigger pulse is delayed for 12 ms, causing the beginning of the next satellite video line to appear closer to the left edge of the display. The PHASE switch is held down until the edge of the satellite video signal moves over to the left edge, at which point the switch is released. This restores proper sync, but, this time, the picture is properly phased.

A worst-case phase error, where the left edge of the picture was all the way at the right end of the 250 ms line, would require 20 line pulses to correct (250/12). Since the line pulses occur 4 times each second, the phase switch would have to be held closed for only 5 seconds (20/4). This is entirely ample since about 20 seconds is actually available for phasing at the start of each APT frame. The action of the phase circuits in stepping the picture into place is shown in Fig. 11.

Horizontal deflection (Fig. 5). The 12 ms trigger pulse at "B" turns on Q3 for the duration of the pulse,

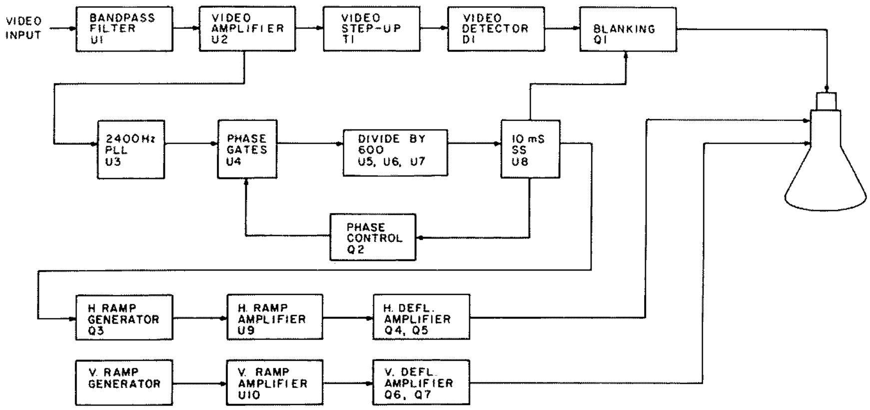

Fig. 2. A block diagram of the monitor signal processing circuits.

discharging the 4.7 uF capacitor in the collector circuit. When the trigger pulse is finished, this capacitor begins to charge through the HORIZONTAL SIZE control, producing a voltage ramp that is amplified by U9. The output of U9 drives the complementary output transistors (Q4 and Q5), which have the deflection windings in their emitter circuit (pins 5 and 6 of the main board). Feedback to the inverting input of U9 via the 100k resistors helps to linearize the deflection waveform. The HORIZONTAL CENTERING control feeds a voltage to the inverting input which provides centering of the trace.

Vertical deflection (Fig. 6). The vertical circuits, with a few exceptions, function much like the horizontal circuits, with the vertical deflection windings connected to pins 3 and 4 of the main board. The differences involve the use of a much larger discharge capacitor (2200 uF) to accommodate the 200-second sweep interval and the fact that the capacitor is cycled by a switch (the sweep switch) rather than a transistor. In the RUN position of the DPDT center-off sweep switch, a reed relay (K1) on the main board is pulled in, causing its contact (K1A) to short out the capacitor and reset the sweep at the top of the screen. When cycled to the center-off position (RUN), the contacts of K1 open, permitting the capacitor to charge and initiating the sweep down

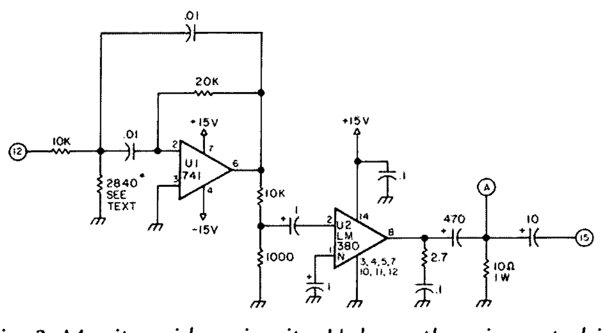

Fig. 3. Monitor video circuits. Unless otherwise noted in this and other schematics, all resistors are ¼ W, 5% carbon film, all decimal value capacitors are 50 or 100 V dipped mylar, all capacitors between 1 and 10 uF are 16 to 35 V tantalums, and all higher value capacitors are aluminum electrolytics rated at 16 V. All unmarked diodes are general-purpose switching types (1N457, 1N914, etc.). Circled numbers refer to board pinouts, while circled letters refer to interface points on other schematics.

the screen. The other position of the switch (FOCUS) grounds the bases of Q6 and Q7, centering the trace on the screen. This position is used to focus the CRT or the film camera and also serves as a standby position when the monitor is not displaying pictures. The low-resistance vertical windings would cause one or the other of the deflection transistors to draw excessive current if left for long periods in the RESET or RUN positions. In the FOCUS position, neither transistor is drawing current, and they will sit indefinitely without overheating.

Mainframe wiring (Fig. 7). Much of the mainframe wiring has been covered in previous circuit descriptions. In order to eliminate the chance that power transformers would cause unwanted deflection of the scanning beam, it is suggested that the power supply be remoted from the main cabinet. The mainframe does contain the +5, +15, and -15 V regulator ICs, driven from the unregulated voltage buses from the remote supply. If the regulators were mounted on the supply itself, you would get unwanted voltage drop in the connecting cable. In addition, the mainframe contains the high-voltage module for generating the +7-10 kV required for the CRT external anode. The high voltage module will be discussed in detail in the construction section. Regardless of the approach taken, however, it is desirable to power the module from its own regulators to minimize interaction with other circuit components.

Power supply (Fig. 8). This supply is one possibility for generating the required voltages. A low-voltage transformer (T3) provides the unregulated voltages via a bridge rectifier and filter capacitor network. The +350 volts required for the internal anode and focus grid of the CRT as well as the BRIGHTNESS network is obtained via a conventional power transformer (T2) and a full-wave rectifier assembly. T2 also provides the 6.3 V ac required by the CRT filament. The mainframe and power supply circuits are shown with Cinch Jones P-808-AB and S-308-AB connectors, respectively. An 8-conductor cable with an S-308-CCT on one end and a P-308-CCT on the other is used to interconnect the monitor and its supply. The power supply is turned on via an ac lead actuated by an SPST switch (S3) on the mainframe.

Construction

Main Circuit Board

Fig. 9 shows the land layout for the main circuit board which carries most of the active circuits. If you do not have facilities for making boards, this particular board is available—a point that will be covered at the end of the article. The component layout is shown in Fig. 10 as viewed from the component side of the board. The main puzzle in wiring the board is the cluster of unused holes between the LM380 and the LM565. These holes mark the demise of an idea that was better on paper than it was in prac-

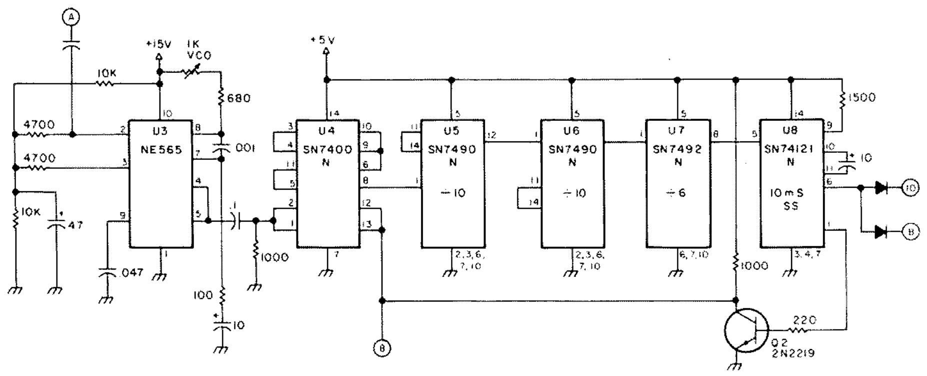

Fig. 4. Monitor sync and phasing circuits.

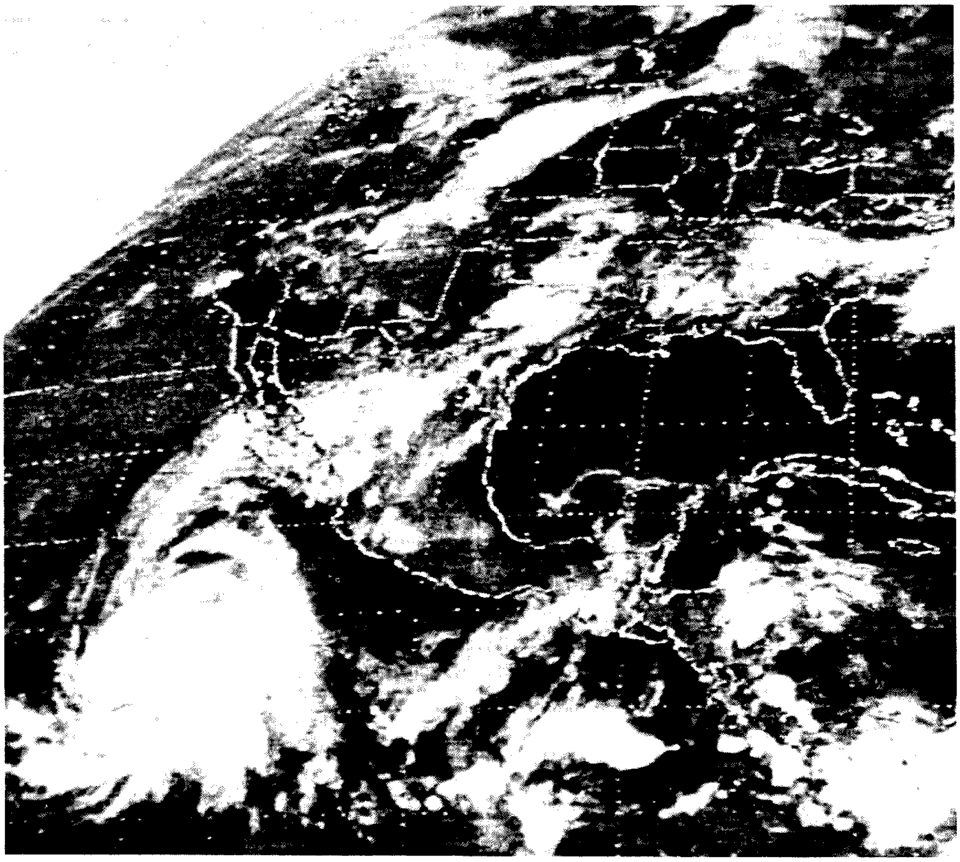

Photo C. An IR frame from GOES E displayed on the prototype monitor. Despite the small screen size, the picture is relatively clear, showing a major tropical storm off the west coast of Mexico. The IR format displays cold objects as white (space and high cloud tops), while warmer areas are darker. Note the warm surface temperatures in the southwestern US and northern Mexico in this frame. The use of a somewhat larger CRT would assure the full 800-line resolution in the APT pictures.

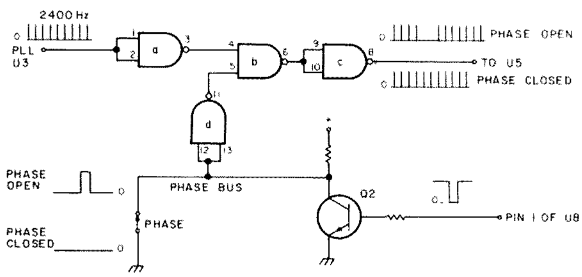

Fig. 4(a).

tice. The idea was to place a limiter in front of the PLL to remove any AM variations in the signal, thus improving the ability of the loop to lock on the subcarrier. That part worked, but the unforseen difficulty was that the limiter was quite sensitive to any noise, and, should it begin to limit on noise, much of the advantage of the PLL was lost. Out went the limiter notion!

In wiring the main board, sockets are suggested for all ICs. They do increase the cost of the project, but they suddenly seem worth it when you discover that you have a bad chip to replace! If you watch the polarity of tantalum and aluminum electrolytics and remember that all the ICs have the same orientation, you will not get into much trouble.

Mainframe

Once the board is finished, the remaining decisions revolve around the packaging style you want to use. The schematics of Figs. 7 and 8 assume that the monitor will go in one box with the power supply remoted on its own chassis. In terms of simplicity, this is probably the best approach to take. In the case of the prototype unit, I opted for a different scheme which got just a bit more complicated. I happened to have a Robot Research fast-scan viewfinder unit which had a suitable CRT, yoke, and HV module, so this was stripped and used as a remote display terminal. The power supplies and main circuit board assembly were mounted on a chassis behind a standard rack panel. Photo A shows the display terminal, and Photo B shows the rack-mounted electronics package. If I were doing the job over again, I would certainly follow the first route I suggested. No matter what scheme you employ, the power supply should be remote from the CRT circuits. It is virtually impossible to package everything in one cabinet and avoid unwanted deflection of the CRT trace by transformer fields. You can try if you want, but plan it so you can pull the transformers with minimal difficulty! When

you actually start to build the mainframe and power supply, you will run into situations where you may want to substitute, so let's look at some of those options.

CRT. The CRT used in the prototype was the original tube that came with the fast-scan viewfinder. It is a type 5M140P7M manufactured by Thomas Electronics, 100 Riverview Drive, Wayne NJ 07470. They made a larger tube for the Robot Model 70 SSTV monitor which is ideal for satellite display and has the same pinouts as the smaller tube used in the prototype. The latter measures only 4.25" × 3.25" (5 inches diagonally) and is really quite small for the display of an 800-line picture. Although the pictures are acceptable, you really can't get the full resolution unless you have a somewhat larger tube.

The one used in the Robot Model 70 is just about ideal. Both of these tubes have a P7 phosphor. This long-persistence phosphor is sufficient to let you see some aspects of the picture in real time in a dark room and therefore has some advantages. P4 phosphors of the type used in black and white TV sets will also work fine, although they do not have the long-persistence feature. If you have a Model 70 SSTV monitor on hand that is doing little these days with the advent of digital SSTV scan converters, you can use this as the basis for a conversion, as it will provide a cabinet, yoke, HV module, and a suitable power transformer. If you are building from scratch, I would suggest contacting Thomas and seeing what is available along the lines of the tubes they supplied to Robot. Their prices are quite reasonable compared to other sources. Failing this, you can check out various small black and white TV picture tubes at your local distributor. Many of these will work fine if you change the socket wiring to accommodate the pinouts. Many of these will have a 12 V filament which can be powered from another LM340T-12 regulator tied to the +LV bus.

HV Module. As mentioned above, the HV module for the prototype came from the Robot fast-scan viewfinder. Other Robot display equipment will furnish similar units. There are many designs available for such modules, and several alternatives are shown in references 1 and 2 and the SSTV section of reference 3. All of these are similar in that a power transistor is hooked up as an oscillator operating into the primary of a standard TV flyback transformer with the HV rectifiers and capacitors in the secondary circuit. The main difficulty with most is that the suggested feedback circuits to run the oscillator are highly dependent on the specific flyback which is specified in each case. Another approach worth checking, if you like to play on the bench, is to use a 555 timer chip as an oscillator at about 20-25 kHz and use this to drive the power transistor as a switch in the flyback primary circuit as shown in Fig. 11. This approach should work with just about any flyback, and you simply choose your primary taps to achieve the desired output voltage.

Transformers. T1 in the video circuits (Fig. 7) is a standard audio output transformer with an 8-Ohm secondary winding (actually used as the primary in this application), and primary windings can be anything from about 1k to 16k. Calectro and others make quite a few that will work just fine—simply look for a "universal" output transformer if you can find one that seems to be custom made for the application. Power transformers are comparatively noncritical as well. If you convert a Robot Model 70 monitor, the power transformer in that unit has all the proper windings in one package. If you go the route of separate transformers, as shown in Fig. 8, you can use the following guidelines in making substitutions.

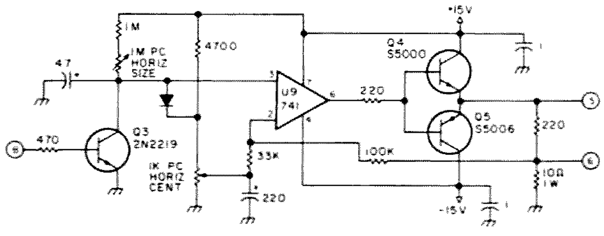

Fig. 5. Horizontal deflection circuits.

The LV circuit requires that the voltage on both the + and − buses be at least 17-18 V for the 15 V regulators to operate properly. The regulators themselves will take up to 30 V when properly heat sinked, so any transformer that will deliver between those dc limits will work fine. It should be capable of supplying at least 1 Amp, and 2 Amps is better yet. The HV supply is low current, and there are a variety of power transformers with 225 and 250 V c-t secondaries in the 25-50 mA range which will work fine. All of these have the required 6.3 V ac filament winding.

Deflection yokes. Any deflection yoke designed for a small solid-state black and white TV set will do the job here. If you have a choice, pick a yoke with higher resistance windings in preference to one with very low resistance.

Cabling. You can do anything you want in this area, from hardwiring the two units together to the use of exotic cable assemblies. Figs. 7 and 8 specify the use of a Cinch-Jones P-308-AB

Photo D. An example of an operational message. In this case, it is a system status announcement and part of the transmission schedule for GOES E. This example shows the old format with white letters on a black background. The current format uses black letters on white.

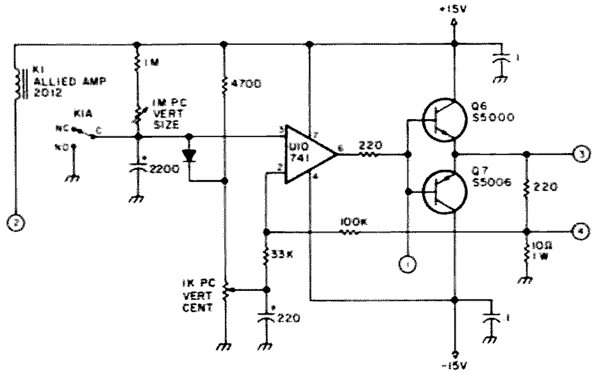

Fig. 6. Vertical deflection circuits.

on the mainframe and an S-308-AB on the power supply. An 8-conductor cable terminated with an S-308-CCT on one end and a P-308-CCT on the other connects the two units. These plugs and sockets are available from almost any distributor and are inexpensive compared to other options. Of course, octal plugs and sockets could be used if you can tolerate wiring the former—I can't! Just be sure to use a socket on the supply and a plug on the mainframe lest you electrocute yourself some evening while wrestling with cables!

General Notes

Only a few general guidelines are necessary in actually wiring up the mainframe and power supply. The first is to adequately heat sink the IC regulators. Dinky sheet aluminum sinks were used in the prototype, and this required the use of a cooling fan to stop them from shutting down when they got too hot. Generous extruded aluminum units are a good investment and will keep the regulators cool. Note that the positive regulators (LM340T series) have their cases at ground potential, so no insulation is required in mounting them to a grounded heat sink. The negative regulators are a different story (the LM320T series). Either use mica washers to isolate the cases from a grounded heat sink or mount them individually on smaller heat sinks, each of which is isolated from ground.

In hooking up the deflection yoke, first measure the resistance of the two windings. One is almost always higher than the other. Use the high resistance member of the pair for Y2 (vertical deflection) and the low resistance one for Y1 (horizontal deflection), and orient the yoke accordingly.

Ordinary hookup wire can be used in most interconnections, but you should use shielded wire in the CRT grid circuit and in the video input circuit to and from the CONTRAST control.

S3, the SPST POWER switch, is best incorporated on the BRIGHTNESS control, so choose a pot with a switch assembly. Wire the BRIGHTNESS pot so that, when the switch is off, the center arm of the pot is at ground potential. This will assure that CRT brightness is always minimum when the unit is first turned on.

The HV module should be mounted quite close to the external anode of the CRT so that only a short length of HV cable is required for the anode connection. The HV module should operate off its own regulators (as in Fig. 7) to minimize its effect on other circuits.

Setup and Operation

Preliminary Setup

By all means, check and recheck all connections prior to powering up. In particular, the +15, +5, and −15 V lines should be checked for proper voltages. To start with, remove U9 and U10 from their sockets and connect the board to the ground, +15, and +5 V lines with the board on the bench.

(1) Connect a frequency counter to the junction of the .1 uF capacitor and 1k resistor at the output of the 565 circuit. Adjust the vco control for a reading of 2400 Hz.

(2) A counter or logic probe should show a 4 Hz signal on pin 8 of U8. A short pulse should be observable on pin 6 of U9 using a logic probe or scope. This pulse should occur at the 4 Hz line rate.

(3) Connect a scope or logic probe to pin 8 of U4. Gaps in the output of 12 ms at the 4 Hz rate should be noted. Use a test lead to ground pin 8 of the main board, and the gaps should disappear.

You can now plug the main board into the powered down monitor. Preset all controls as follows:

CONTRAST (panel)	minimum (max. CCW)
H SIZE (board)	midrange
H CENTERING (board)	midrange
V SIZE (board)	midrange
V CENTERING (board)	midrange
SWEEP (panel)	FOCUS
FOCUS (panel)	midrange

(1) Advance the BRIGHTNESS control to

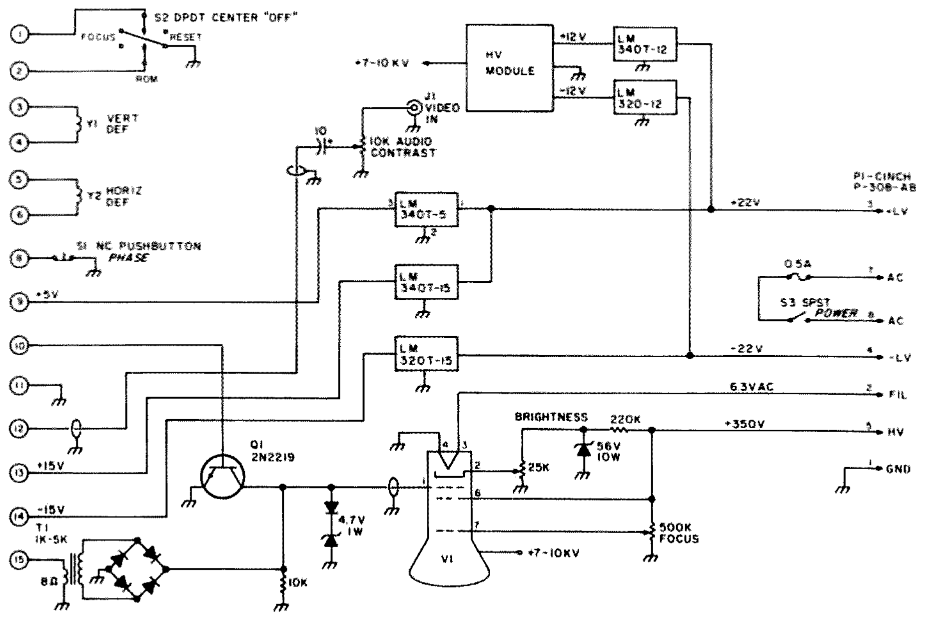

Fig. 7. Monitor mainframe wiring, assuming that all components, exclusive of power supplies, are in one cabinet.

engage the power switch but no further. Allow 5 minutes for the unit to warm up.

(2) Slowly advance the BRIGHTNESS control in a dimly-lit room until a trace is just visible. If the trace is not horizontal, loosen and rotate the yoke until it is. Sharpen the trace with the FOCUS control.

(3) Mask off the largest possible square area on your CRT. This will be referred to as the "viewing area."

(4) Adjust the HORIZONTAL SIZE and CENTERING controls on the main board so the trace extends from one side of the viewing area to the other. Momentarily ground the collector of Q3. The trace should jump to the left edge of the viewing area. If it jumps to the right, you should power down and reverse the connections to Y1 and then reapply power and repeat the size and centering adjustments.

(5) Cycle the SWEEP switch to RESET. The trace should move upward. If it goes down, you should power down and reverse the connections to Y2 and power up again.

(6) With the SWEEP switch in the RESET position, adjust the VERTICAL CENTERING so the trace is even with the upper margin of the viewing area.

(7) Cycle the SWEEP switch to RUN and adjust the VERTICAL SIZE control so that it requires 200 seconds for the trace to move from the top to the bottom of the viewing area. You will probably have to cycle between RESET and RUN several times to get this right, but it is critical if the pictures are to have the proper aspect ratio.

(8) Back the BRIGHTNESS down to the point where the trace is just extinguished in a dark room.

(9) Play a tape-recorded satellite signal into J1 starting somewhere in the middle of a frame transmission. Slowly advance the CONTRAST control to achieve the best swing between black and white. If you go too far, the screen will be completely white due to the action of the white limiting, and, if you don't go far enough, you will lose some information at the black end of the picture signal. At this point, you should see a picture, but it will probably be out of phase. Press the PHASE switch until the edge of the picture lines up with the left edge of the viewing area.

At this point, you have tested all of the elements of the monitor and are ready to display a picture. Generally, you will not have to alter the CONTRAST control settings unless you change the input level to the monitor.

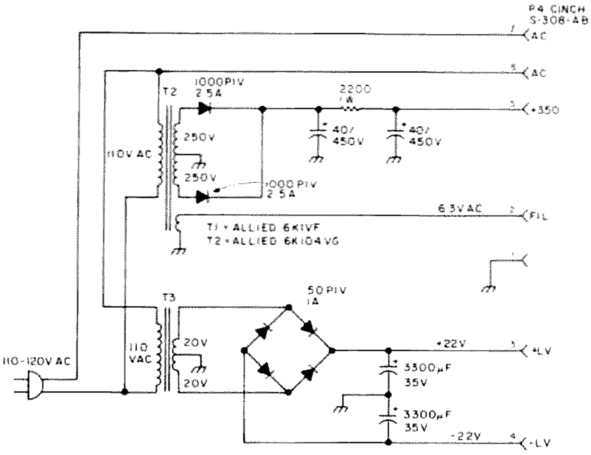

Fig. 8. Power supply circuits.

Operation

Either a Polaroid™ camera with a closeup lens or a conventional roll-film camera can be used to take pictures from the monitor. It should be firmly mounted at the proper distance from the monitor and ideally should employ a cable release to actuate the shutter. Reference 2

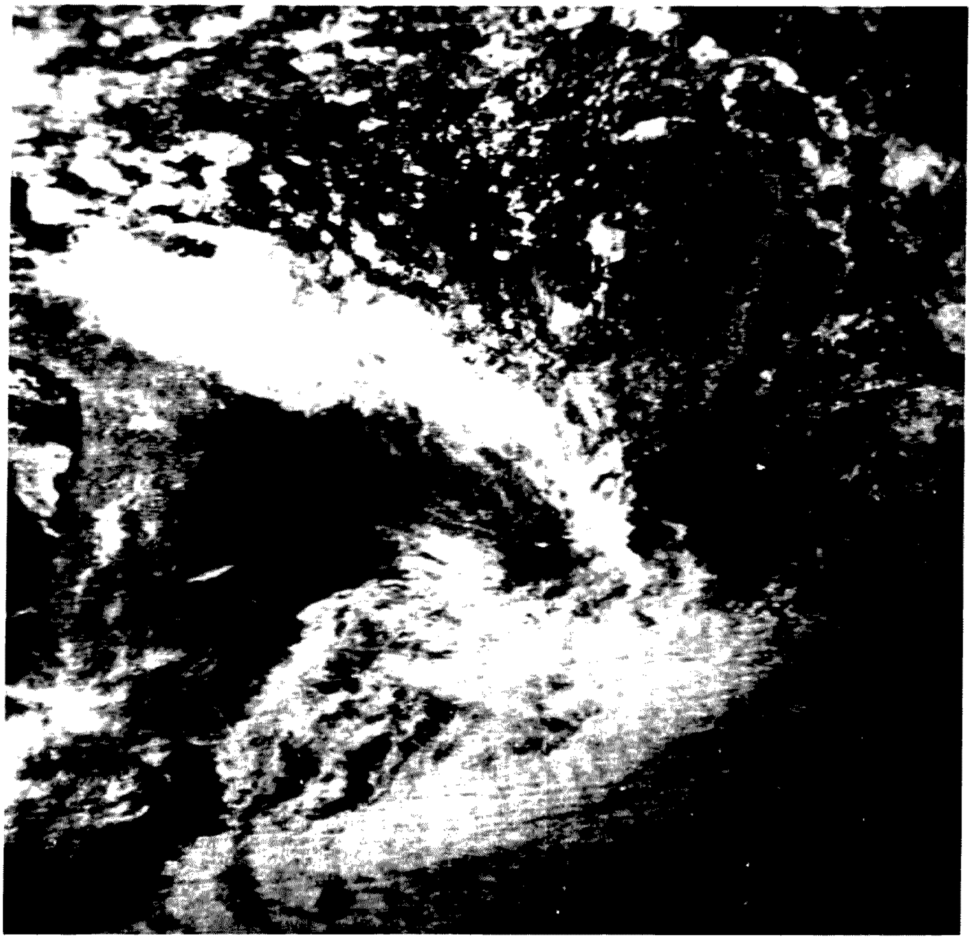

Photo E. A visible light frame of the SE quarter of the earth disk as seen by GOES E showing almost all of South America. This is an afternoon frame, so the eastern limb of the disk is already darkening as the terminator appears, marking local sunset in the South Atlantic.

contains a great deal of useful information about photography from CRT displays, and I won't repeat it here. In each case where the monitor is used, you should allow at least 5 minutes for warmup to get reproducible results. Whenever the monitor is on but not displaying pictures, the SWEEP switch should be in the FOCUS position. When you are ready to display a frame, it can be cycled to RESET.

The picture will begin with a few seconds of start tone—300 Hz modulation of the subcarrier which results in a distinct bar pattern on the trace. When the tone terminates, you should observe a black area somewhere along the trace. Press the PHASE switch to move this to the left edge of the viewing area. 20 seconds after the end of the start tone, cycle the SWEEP switch to RUN and the frame will begin to

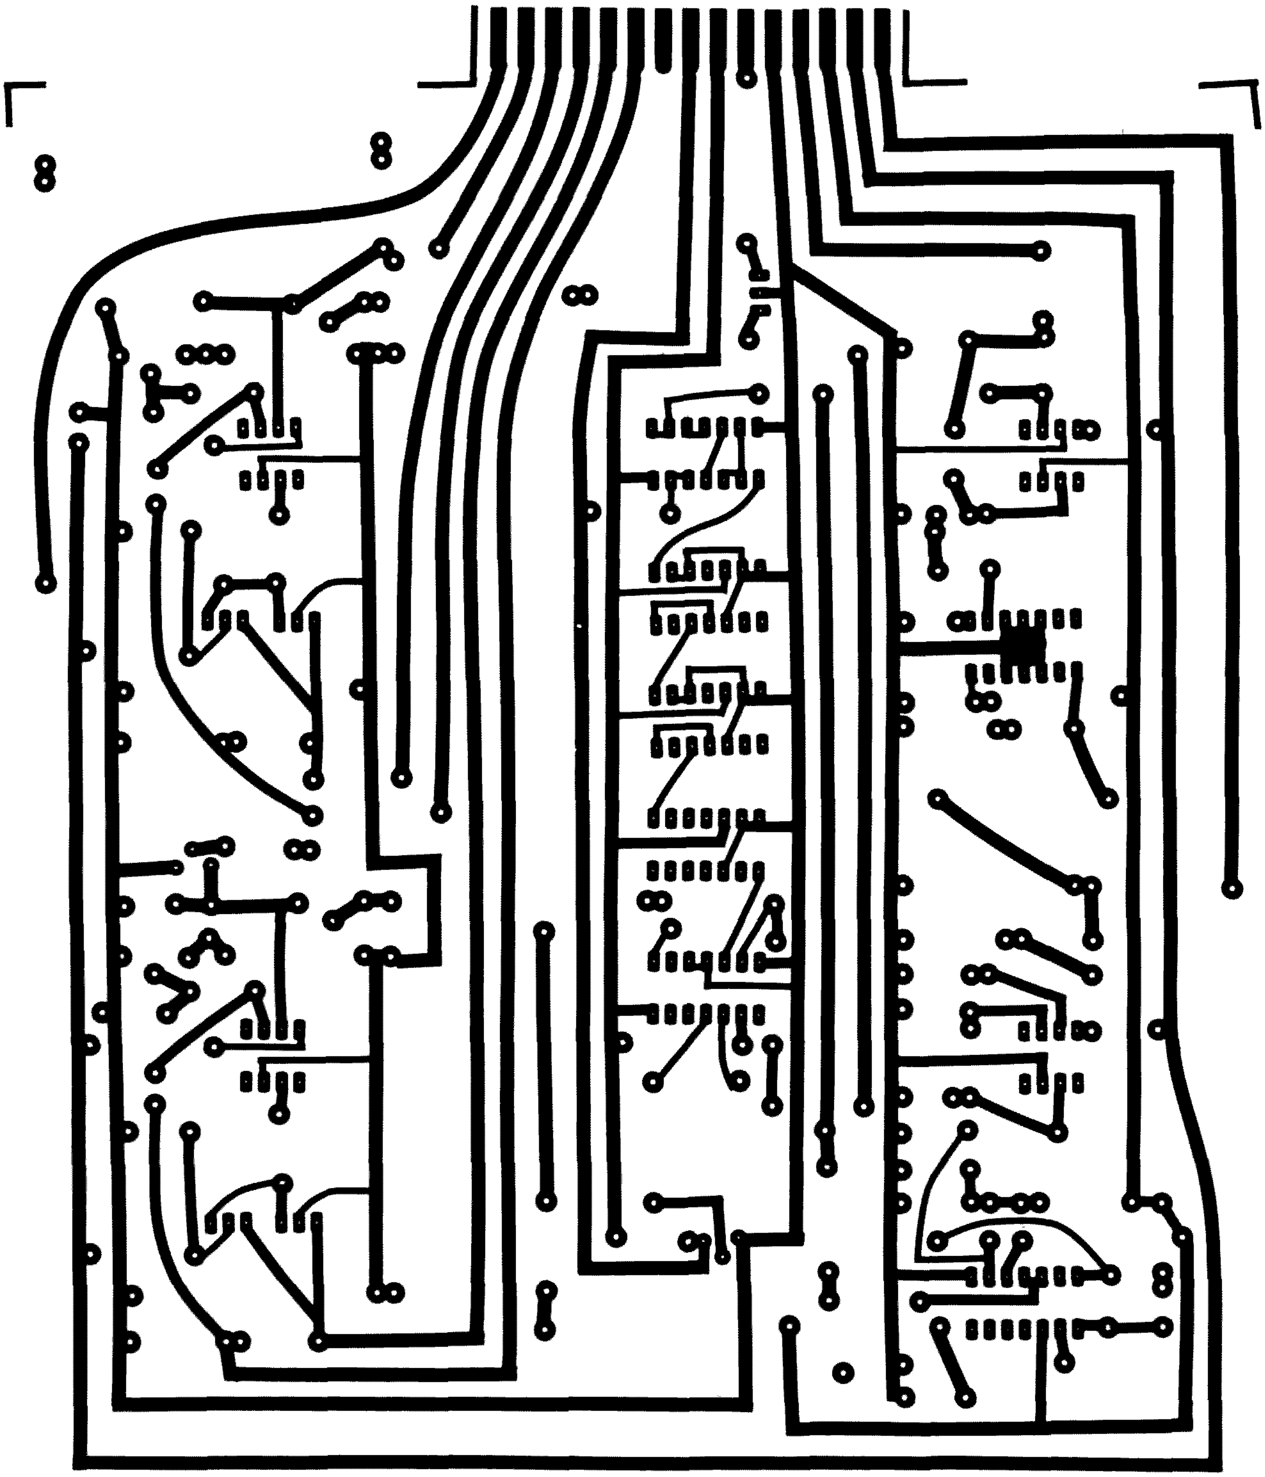

Fig. 9. PC board layout (foil side) for the main circuit board.

read out, beginning with the ID header, followed by the actual frame. About the time the scan reaches the bottom of the viewing area, you will hear a 450 Hz stop tone which tells you the picture is finished. In photographing the display, you should use a completely dark room unless you have a light hood assembly for the camera. The shutter should be opened as you cycle the SWEEP switch to RUN, and it should be closed when you hear the stop tone. If you want to copy another picture immediately, simply cycle to RESET and await the next start tone, otherwise set the switch to FOCUS until you are ready for the

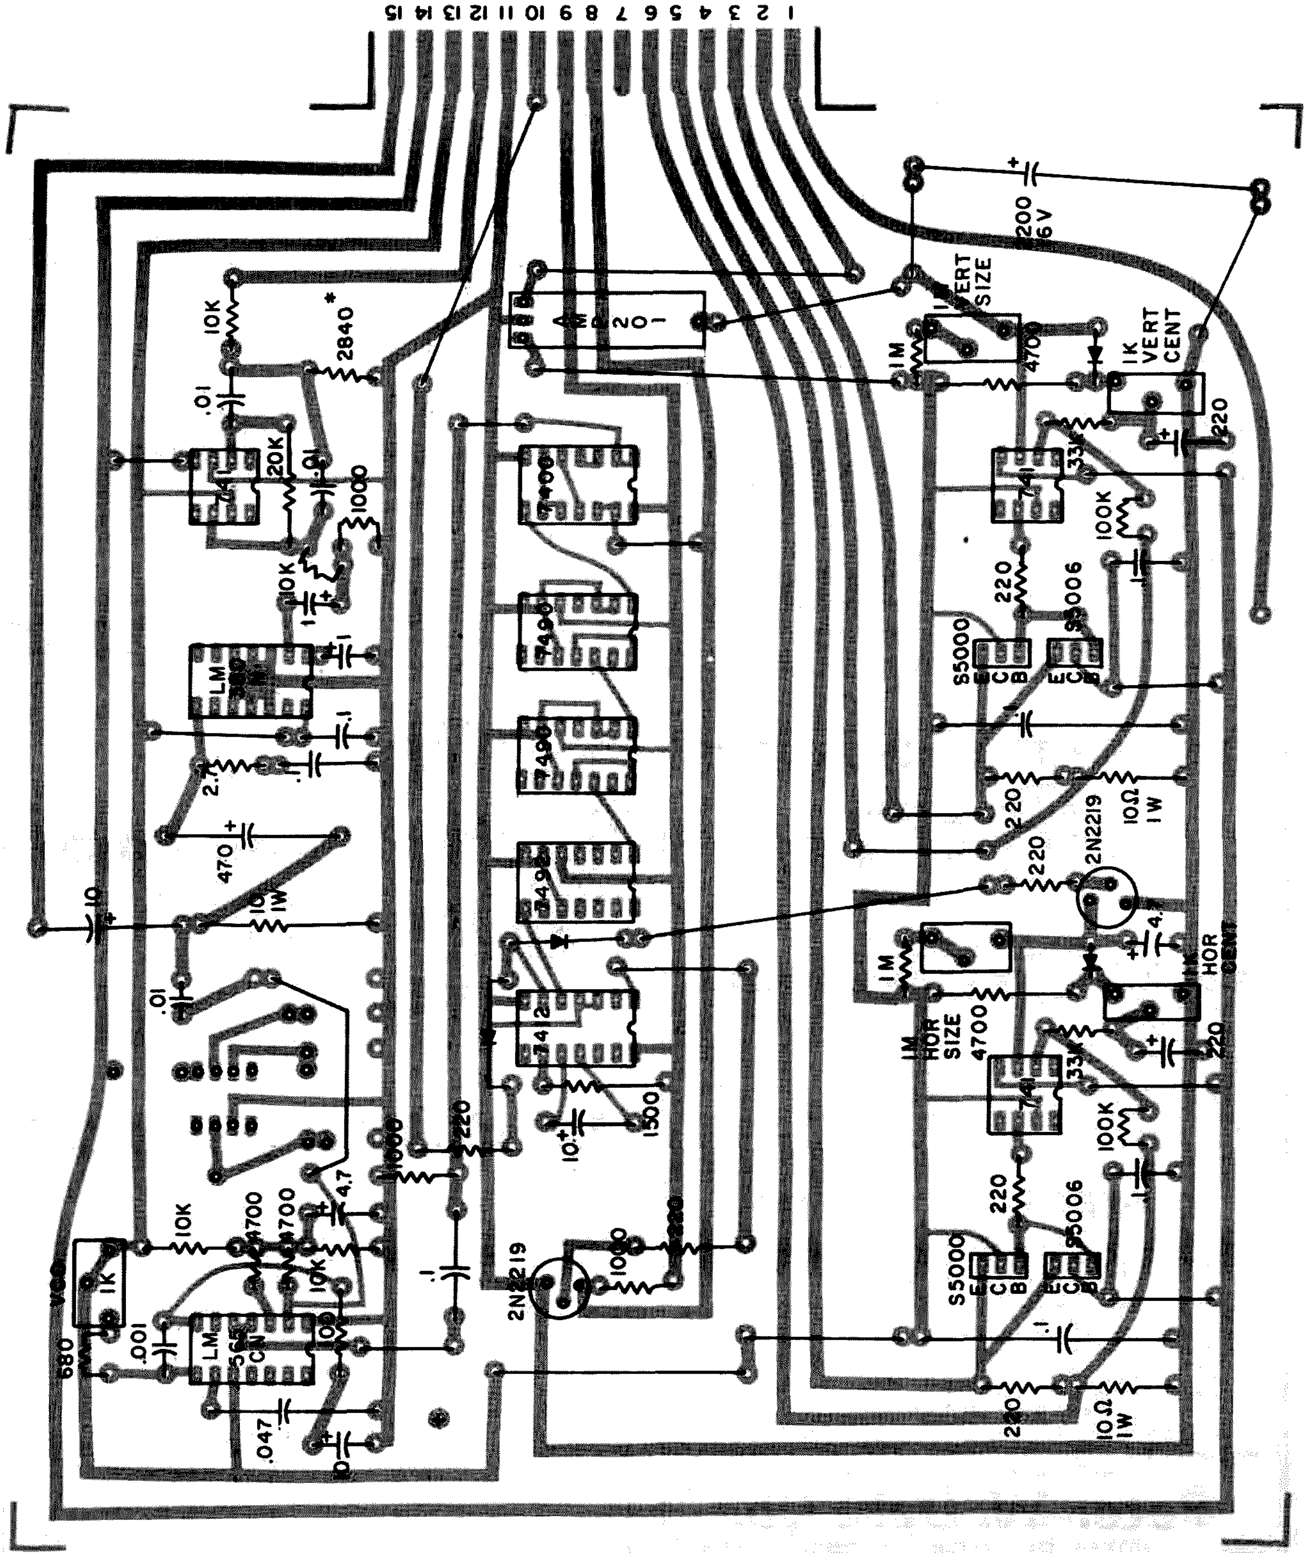

Fig. 10. Component side layout for the main circuit board.

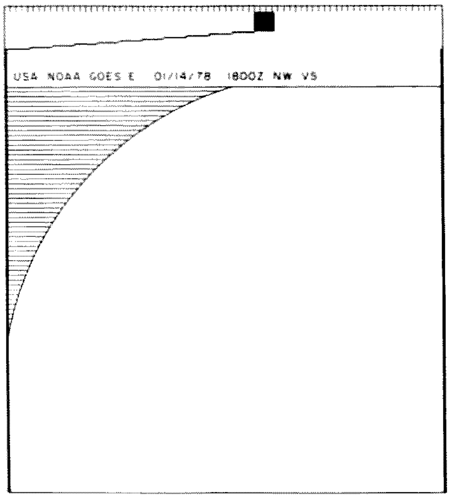

Fig. 11. Operation of the phasing circuits. The top of this segment is the start tone (300 Hz modulation of the subcarrier) where the PLL first locks on the signal. This is followed by a 25-second phasing interval. Note that the edge of the picture, marked by the black bar, is inside the viewing area. When the PHASE switch is pressed, the bar begins to move toward the left edge of the picture where it belongs. When it reaches the edge, the PHASE switch is released and the picture drops back into sync. Note that the last 5 seconds of the phasing interval is devoted to an ID header for the picture. Normally, phasing is done with the sweep switch in the RESET position and the switch is cycled to RUN about 20 seconds after the end of the start tone, permitting the ID header to be displayed.

next frame.

Summary

Photos C, D, and E show typical GOES APT frames displayed on the prototype monitor. Despite the small CRT size, the pictures are quite acceptable. The use of a larger CRT would sharpen them noticeably, however. With a larger CRT, the display can come quite close to the results achieved with a good photographic fax system with considerably less fuss. Polaroid film will give you almost instant prints with little bother, or the use of roll film will let you prepare enlargements at any size you desire.

This is actually an easy unit to build and operate and probably represents one of the easiest ways to get into GOES picture display. With a few modifications, the unit can also be used to display VHF pictures from the new series of polar orbiting satellites that became operational with the launch of TIROS N.

Circuit boards are available for this project from METSAT Products, Box 142, Mason MI 48854. The main circuit board, G-10 epoxy, drilled and plated, and a documentation pack costs $50. If you want to go this route, ask for minikit GM-1. ■

Batteries Dead?

— take preventative measures

Your worries are over if you use battery status indicators.

One of the problems associated with battery-operated equipment is knowing that the battery supply has been turned on and/or that the battery voltage is still within suitable limits. Suitable limits might mean the voltage range necessary for a circuit to perform properly, or the upper voltage limit that a rechargeable battery pack should have when it is properly charged and the lower voltage limit when discharged to the point where its usage should be discontinued before the battery pack is damaged by too deep a discharge.

Depending on the capacity of the battery used, one can "afford" only certain types of battery status indicating circuits. Obviously, for a small piece of test gear operated from a 9-volt transistor radio-type battery, even the use of an LED or the smallest incandescent lamp available will take too much current (15 to 20 mA) compared to the milliampere hours (mAh) rating of the battery (62 mAh for an inexpensive 9-volt type). On the other end of the scale, using a higher capacity battery source, one can "afford" even elaborate battery status circuits that provide detailed information regarding battery condition.

This article explores several interesting battery status circuits including ones that will work with even the lowest capacity battery source to more elaborate alphabetic indicators. Some of the circuits use discrete devices although ICs are available to do the job. Discrete device circuits don't take significantly more current and use commonly available components, whereas the ICs may not be readily available.

Before getting to the circuits, one might mention meters as battery status indicators. The availability of inexpensive, imported microampere meters might appear attractive to use because of the very low current drain. But, if one calculates the current change indicated by the meter as the battery voltage changes, it might not be very significant. The current change indicated depends on the internal resistance of the meter and any added series resistance. As an example, if a typical, inexpensive 500-microampere meter in series with a suitable resistor is placed across a 9-volt battery, the meter indication might only decrease by about 1/3 scale as the battery voltage sinks to 6 volts. This is not a very obvious indication that the battery voltage has fallen to the point where it will significantly affect the performance of many 9-volt circuits. Of course, there are often small battery status meters available during parts sales, but a true indication is obtained only when the meter is used for its designed purpose.

After having left many 9-volt-powered transistor checkers, bridges, and even portable receivers turned "on" instead of "off" after usage, with resultant battery loss, the circuit of Fig. 1 was finally discovered. It uses an LED as a battery "on" indicator, but the LED is flashed at a low duty cycle so the average current drain is only about 1 mA. The 2N4870 unijunction transistor forms a simple pulsed oscillator circuit which in turn drives a 2N2222

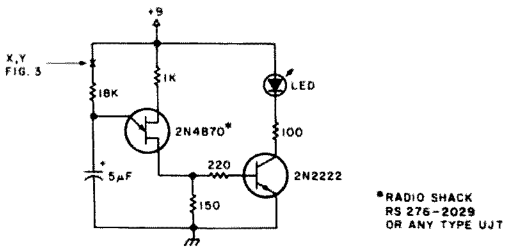

Fig. 1. Due to the low duty cycle of this flashing LED circuit, the average current drain is 1 mA or less.

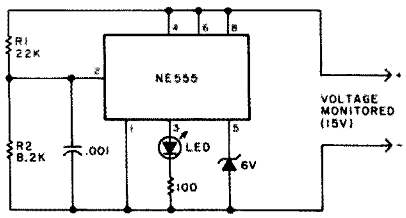

Fig. 2. The NE555 will trigger the LED on when the monitored voltage falls to 12 volts. The ratio of R1 to R2 only needs to be changed if it is desired to change the voltage point at which the LED is triggered.

switch that turns on the LED. The LED flashing rate and the battery voltage range which may be accommodated can vary over a wide range by the suitable choice of R1, R2, and C1. Flashing rates from 2 to 20 per second are the most attention-getting, while still keeping the average current consumption low. The battery voltage can be anything from 3 volts on up. The values in the circuit of Fig. 1 will produce a flashing rate of about 5 times a second from a 9-volt battery. A small amount of experimenting is necessary, particularly with R1 and R2, for other battery voltages. They should be raised in value for higher battery voltages and lowered in value for voltages below 9 volts, although their value is not at all critical. The cost of the batteries saved will rapidly repay the cost of the components for this circuit if you have any tendency at all to forget to turn off battery-powered equipment.

The circuit of Fig. 2 is an undervoltage indicator. It is particularly valuable when using nicad battery supplies since such batteries can be damaged if they are too deeply discharged. This circuit is useful only if there already is some sort of indicator on a piece of equipment informing the operator when it is turned "on," since this circuit will tell the operator when it is time to turn the equipment "off." As shown, the circuit is used to monitor a 15-volt battery source. The ratio of R1 to R2 is such that the LED will illuminate when the battery voltage falls to 12 volts, which is approximately 80 percent of the fully-charged voltage of the 15-volt nicad supply. The voltage value at which the circuit switches on can be controlled by changing the ratio of R1 to R2. The circuit can also be used on other supply voltages in approximately the 9- to 18-volt range. The circuit is quite sensitive and the turn-on of the LED when a low voltage condition is reached is distinct and sharp. If one wanted absolute protection, pin 3 of the IC can also be used to drive a small relay which would automatically turn off a piece of equipment. This might not be a bad idea for some operators who insist on a last transmission although their nicad battery packs are about to be damaged.

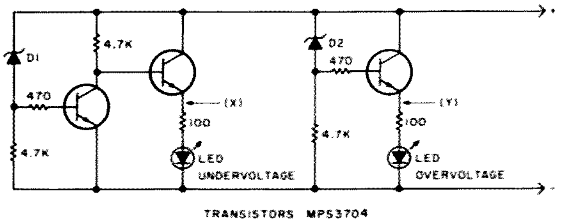

Fig. 3. This circuit will ignite the appropriate LED if the monitored voltage goes below or above the value determined by zener diodes D1 and D2.

The circuit of Fig. 3 does not indicate when a supply is on, but it can indicate both an undervoltage and an overvoltage condition. This may be useful when charging certain types of battery packs where a fully-charged condition is indicated by a specific voltage level. The circuit can also be a warning device to indicate that the output of some device, such as a portable generator, is not within acceptable lower and upper voltage limits. The circuit can be set up for completely independent lower and upper voltage limits and the limits can be as far apart or as close together as desired. The critical components are the two zener diodes: D1 to set the undervoltage indication value and D2 to set the overvoltage indication value. These diodes have to be fairly exact in value. For instance, if one wanted to set the upper voltage indication at 15 volts, one would have to use a 15-volt, 5% tolerance zener or test a bunch of 10 or 20% tolerance zeners until a suitable diode is found.

The circuit of Fig. 3 provides a steady LED display for low and high voltage. A more attention-getting display can be obtained by combining the circuits of Figs. 1 and 3 so a flashing LED display is obtained. In this case, the LEDs shown in Fig. 3 are not used and the points marked X and Y are connected to the similarly-noted points in Fig. 1. Note that two circuits of the type shown in Fig. 1 are necessary.

The circuit of Fig. 4 provides a battery status display using a 7-segment LED readout. A low voltage state is indicated by display of "L", a high voltage state by display of "H", and when any in-between voltage is sensed, the display is a constant "F". One can arrange the connections to the readout to display differently depending upon one's fancy. For instance, one could have the display read "1" for high, "2" for in-between voltages, and "3" for low voltage. Another idea might be to have all segments on the readout active for a high voltage state and then progressively switch off segments for lower voltage states. By studying the diagram and the logic states to get the L, F, and H display, one can arrange other displays on the readout. The zener diodes are, again, critical in value if the circuit is to react when specific voltage levels are sensed. ■

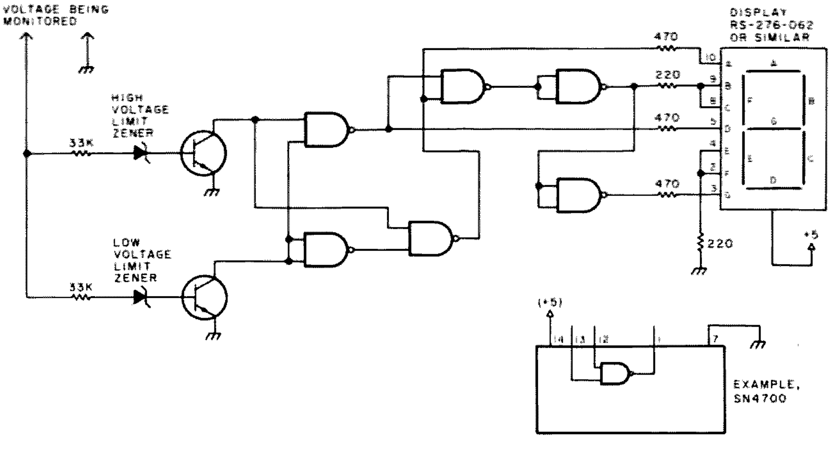

Fig. 4. This circuit uses an LED readout and displays an "L" when the monitored voltage is low, an "H" when the voltage is high, and an "F" when the voltage is between the low and high limits.

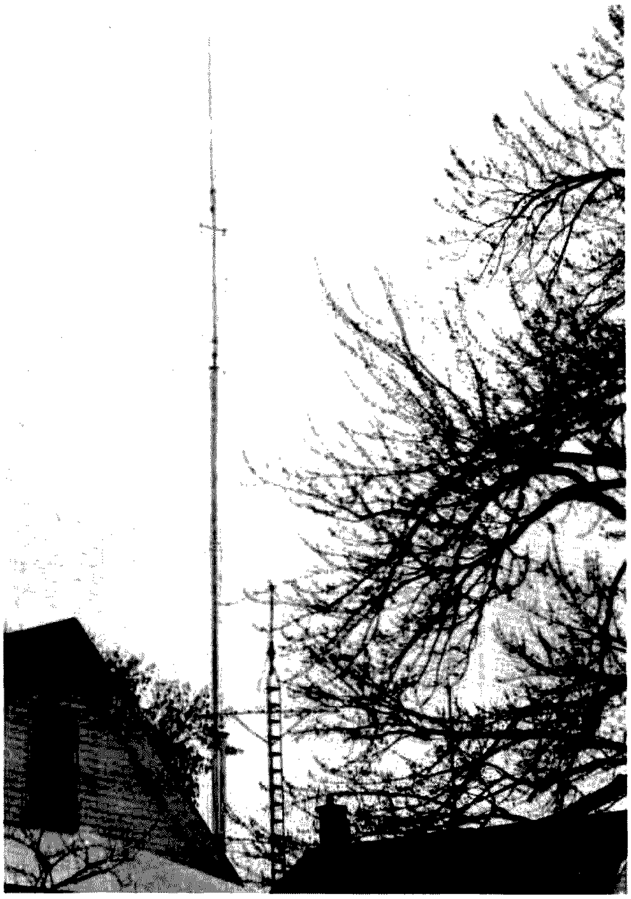
How to Nab a Jammer

—another use for 220

It's the Omaha VHF posse vs. the Red Rider.



This shows the 146.40/147 antenna with a 100′ tip and, more difficult to see, the 222.34/223,44 repeater antenna with an 85′ tip.

John Gebuhr WB0CMC
2340 N. 64th St.
Omaha NE 68104

It all started about a year ago when Omaha VHF was plagued by a character who went by the handle of "Red Rider." Every Saturday night without fail, for several weeks, he would come up on the 34-94 repeater: "Breaker one nine, this here's the Red Rider." Usually, no one would answer him (which was the best policy in the long run), and the first few weeks he shouted obscenities until he found out the repeater got shut off when he did. We would get fixes on him and close in "for the kill," and suddenly he would QRT for 15 minutes to a half hour and show up again on the other side of town.

After the 3rd week of this, it became obvious that he was listening to us on other 2m frequencies as we would track him. We used some very uncommon ones, but he obviously had a synthesized receiver. His transmitters were identified as a PLL type of moderate power (10-30 W) and also a low-power crystal, probably handheld, unit. (This was later verified.) The two transmitter fingerprints were watched for on legal transmissions, but never appeared until several months later.

One night, we used 5 or 6 ten meter mobiles and spotted his car, but he saw us about the same time and we didn't get a license number. We saw that evening that 10 meters would work, but to get enough 10 meter mobiles to do a good job proved a hassle, as did propagation.

A couple of days before, I had received a flyer from Clegg which offered ten 220 MHz radios for the price of eight. I asked the rest of the guys if they

would be interested in going together on this, and there seemed to be some interest. I took a chance and ordered ten. About ten days later they came, and, by nightfall, six had gone out the door. That was on Thursday night. By Saturday, the rest of them were in service and crystals were ordered for two repeater pairs and another simplex frequency. The following Monday, ten more Cleggs were on order, and two weeks later, there was a 220 repeater in Omaha with 19 users.

If one wonders what happened to the 20th radio, it is now the upper 34-94 repeater in north Omaha. The entire receiver lifted out of the case by loosening four screws and was put in a shielded box. The COR is a reed relay driven from the squelch circuit. R61 is removed from B+ and reconnected to the base of a PNP transistor, the emitter is connected to B+, and the collector goes through a relay coil to ground. A diode was hooked across the relay coil to reduce spikes (hysteresis diode). A 25 uF capacitor was later added to provide a short squelch tail. The LED was added as a cosmetic device.

Cavities were later made out of some 3" transmission line donated for the cause. A handful of "SMA" series connectors was used in the duplexer (because they were free) and a half pound of solder.

The repeater finished, we got permission from Motorola to put the thing up on the Woodmen Tower (300'+ above average terrain) for the weekend. The top of this building is a protected site and has what looks like a crewcut of top-quality commercial antennas — ATS, paging, business, railroad, and many others. I had managed to pack the entire repeater into a suitcase, duplexer and all, and we carried it up to the top, climbed out on the roof 425 feet above the street, and clamped a Ringo Ranger to a lightning rod. We took the repeater out of the suitcase, set it up, and put it on the air in about 15 minutes. The duplexer didn't need any retuning, and we were off to hunt Red Rider.

We had some success that night, but, unfortunately, Red didn't stay on too long and we didn't get him. For about four months, 220 was probably the best-kept secret in Omaha. And in those four months, we compiled a nice fat file including names, addresses, vehicle descriptions, footprints, and real dog smelling prints, and sent it to the FCC in Kansas City. The night that we got a positive ID on the Red Rider, the comments heard on the 2m 34-94 were, "This is the first Saturday night I'm gonna sleep soundly for a long time," and "Bad guys 31, good guys 1; that kind of evens up the score, doesn't it?"

The only thing that got on people's nerves after that was that it took the FCC about three months to do anything about it. Since the FCC came to town, though, there has been almost no deliberate interference or other flagrant rule violation.

By this time, it was obvious that 220 was here to stay, and there is now a second repeater here cross-linked with the 2m 40-00 machine, making possible, for many people, full duplex operation.

The second repeater is a Midland 13-509, which turned out to be the exact same radio as the Clegg, except for the case and name, right down to the Japanese fingerprints on the PC board. As it turns out, the Cobra 200 is also identical to the above two radios and is the cheapest

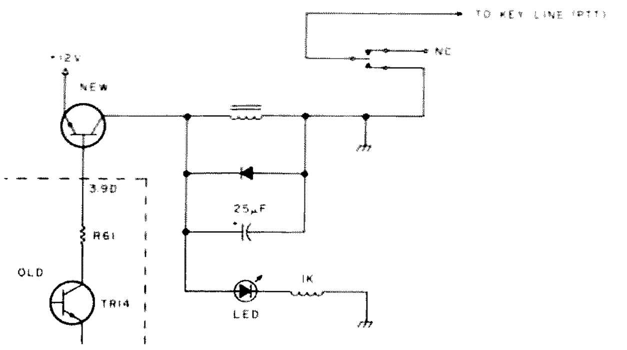


Fig. 1.

one on the market.

As with most ham gear, all three of these radios are imperfect and it is a lot of fun modifying them for various reasons.

Modification #1 eliminates the somewhat long squelch recovery time or reduces it to insignificance (with the squelch set near the edge of operation, it may take up to a full second for it to recover). By changing C89 and C91 from 4.7 uF each to 1 uF each, the recovery time is very fast without significantly impairing the operation.

Modification #2 removes the lamp behind the channel selector and replaces it with an LED. The LED is connected in series with R60 on the receiver board, and R60 is changed from 100 Ω, 1 W to 47 or 56 Ω, ½ Watt. The entire operation reduces receiver current from over 200 mA to about 140 mA. Modification #2(a) removes the meter lamp or puts a switch on it, reducing receiver current to around 60 mA, easily in the portable range.

Modification #3 removes the TX lamp and replaces it with an LED in series with the relay coil, reducing the low-power transmit current from 800 to 700 mA. The only degradation in performance this entails is that the transmitter must have 10.5 V minimum instead of 9.1 V to key properly. So, total low-power current drain is 1.1 A stock minus meter lamp minus channel lamp minus key lamps = 700 mA, clearly a significant saving. A 12 V gel cell will run the radio for a couple of days and still have power to spare (1.5 Ah).

Modifications #4 and #5 change the SO-239 to a BNC for quick disconnect, lower loss at this frequency, and the capability to use a rubber ducky. The power leads are removed and a quick disconnect plug and socket are installed.

Modification #6: The zener, D6, next to the 56 Ω resistor (in Mod. #2) is disconnected from the 9 V line as is the 9 V side of the LED/56 Ω network. An NPN 1 W resistor is put in as a series regulator, and a 1k resistor is added as shown in Fig. 2. This modification further reduces receiver current by 5 to 10 mA, and, as the zener is a ±5% device, the performance of the receiver is completely unchanged. The 9.1 V line should now be about 8.5 to 8.7 V.

I might at this point say that the part numbers above mentioned are the same for all three makes of radio. The instruction book that comes with the Cobra is far more complete than that with either the Clegg or Midland. It is a service manual, whereas the other two have only a schematic and block diagram.

I don't know when I've seen a radio that is more

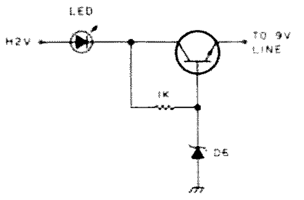

Fig. 2.

fun to play around with and tinker in and modify than these. They are very easy to work on, are laid out well, and come apart quickly.

The first two batches of Cleggs probably sparked the biggest antenna building boom Omaha has ever seen. The two amateur stores had nothing and the only antennas available for 220 were from the local Larsen rep, and they were for mobile only. For the base antennas, most built 5/8-wave or ¼-wave antennas, and a few cut down Ringo Rangers to the proper dimensions.

There are only two minor problems I have seen with these radios that are really in the problem category and they are: First, the mike hanger button on the back of the mike is riveted too tightly, and, if it is dropped, frequently a crack appears between the button and the PTT switch. The second is the tuning on the output of TR 21. If one is not careful in tuning it, it can create spurs due to oscillation of the stage. A simple verification can be made of this by keying the transmitter and pulling the crystal while keyed. If the power meter shows output, it's oscillating. If the meter goes instantly to zero, it's probably not and is set alright.

One might notice a much greater difference in antenna position compared to 2m; because of the shorter wavelength, moving the antenna 5 or 6 inches one way or the other may make as much difference as a 2/3-scale reading on the S-meter. Objects which only partially reflect and partially absorb on 2m become good reflectors on 220, and, consequently, the interference fringes are much more pronounced (see optical behavior in any general physics book).

Looking to the future, I see 220 as a band that will grow by leaps and bounds in the next 2 or 3 years. The 220 class E is dead, there is a vast empty space there now in most parts of the country, and, as 2 meters becomes more congested, 220 and 440 are the next logical places to go. I also think one of the reasons 440 is so much more popular than 220 is the availability of used VHF gear retired from commercial service at very low prices. But, as people are finding out, 220 seems to take the best of both 2m and 440 plus a few points all its own and offers the individual a new playground to do as he wishes on VHF.

As a footnote to this, one of the 220 repeaters has become an administrative frequency for ARES and other such activities because of the large and ever-growing number of people who have 2m crystals in their scanners. 146.94 is a hot-selling rock in Omaha Radio Shack stores. People are finding out that, for weather watch information, 146.94 is where it's at. Inasmuch as we have stations at NWS and a 3rd weather wing at Offut AFB during severe weather and tornado watches, there are a number of bits of information which should not be passed over 2m, so, rather than tie up telephones or take a chance on upsetting the nonamateur public on 2m, they go via 220 as there are no scanners made which will pick it up. ■

This Station Plays Beautiful CW

—with a Morse keyboard

Roll over, Beethoven!

The international Morse code (CW) is a digital musical language. If you happen to be a straight-key master, such as K9ZTH, you can make music to rival that of Mantovani. If you happen to be blind, a talented pianist, composer, piano tuner, and a ham, you can even write a concerto using this musical language. Ol' Rip Snorter John (W9ORS) is such a person and is presently writing *The CQ Concerto*. The first few bars are great and I can hardly wait for the finished work, because it will include a CW message hidden within beautiful music.

Because timing is tricky, it is a challenge for a composer to work the unique rhythm of CW into conventional music. The dot is the basic unit of time in precise code. The syllable space between dots and dashes also requires one time unit. A dash is exactly three time units long and matches the letter space. The interword space is the mystical number 7.

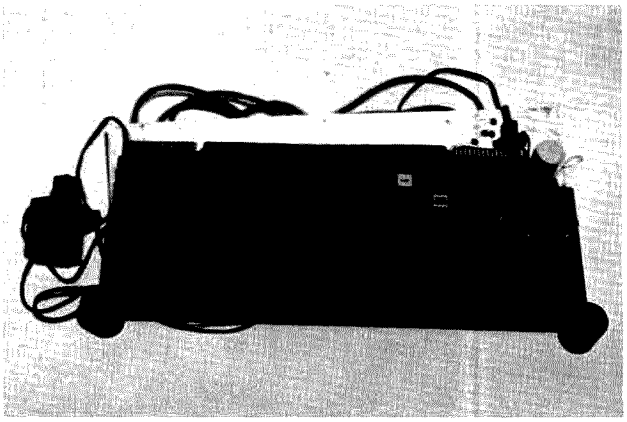

Photo A. Diode matrix (front) forms 8-bit binary code. The 13 ICs (back) provide logic to convert binary code to Morse code. Keying and VOX relays at lower right.

The digital aspect of CW makes ICs ideally suited for application in keyers, keyboards, and readers. In the CW language, spaces are as important as the dots and dashes. Often hams forget that spaces are important. At times, a ham will send, "my nag is . . ." It is easy to run the "m" and the "e" together so that instead of having a *name*, the ham is a *nag*. Even old-timers with bugs and weighted keyers have problems. With dots set for 40 words per minute and dashes at 20 words per minute, the sender speaks with an accent. He can communicate with his own kind who have the same accent, but others who prefer the musical rhythm of good code have difficulty copying 20 words per minute even though they are capable of handling 30 words per minute of perfect code.

The importance of spaces and the application of ICs has been recognized by others and many fine articles have been published (see references). The electronic keyer with its supervised dots and dashes has improved CW communications in recent years. However, proper operation of a keyer takes a certain amount of musical skill which many of us do not have. As a result, the average CW QSO is still well below 20 words per minute.

The keyboard encoder offers additional improvement in communications with the CW language. Good commercial equipment is available, but high prices discourage many potential users. Articles on home-brew projects are being published, and any ham who likes to solder (or wire-wrap) can have a keyboard.

My prototype keyboard used TTL and a 9-bit code. I

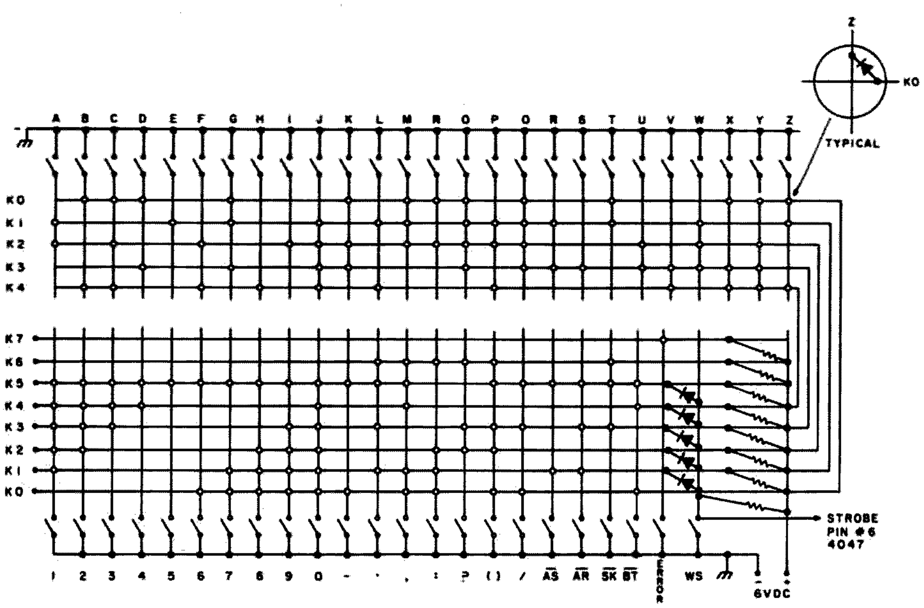

Fig. 1. Diode matrix for alphanumeric characters. All diodes are 1N4814 or equal. Resistors are 10k, ¼ Watt. Switches—typewriter keyboard.

used a diode matrix to generate a binary code and digital logic to convert it into dots and dashes. The TTL scheme worked fine, but as I was putting on the finishing touches, a regulator in the power supply failed and fried a $17.50 40 x 9 first-in, first-out (FIFO) memory chip. About the same time, K2BLA published a circuit that could be constructed using about $30 worth of parts. Also, WB5IRY wrote about the possibility of TTL becoming obsolete. Both of these writers were generous in their praise for CMOS and emphasized how easy it is to construct a power supply for CMOS. With this motivation, I switched to CMOS and an 8-bit code.

After trying high-frequency keyboard scanning, such as is used by K2BLA and in calculator keyboards, I have decided that diodes are still beautiful (Photo A). They are rugged, cheap ($2.84 for this circuit), and even though 142 diodes have 284 leads, the hookup is so simple that it can be made while the XYL is talking. There are no glitches, and troubleshooting is so easy that it can be done with a VOM.

Considering the possibility that some hams may not be any more advanced in the art of applying ICs than I am, some basic fundamentals about logic devices used in this circuit will be included for convenience. Being an electrical engineer specializing in power, I am more familiar with 500 MCM cables and 10,000 kV-A transformers than I am with the 14- and 16-legged bedbugs normally called ICs. If you happen to be a digital pro, skip a few paragraphs and go directly to the schematics. Before going into the details of how the circuit works, let's review a few basics concerning solid-state devices that are used in the system. Use Fig. 2 for reference.

Flip-flops can be considered remotely controlled switches which have several input control lines. Two 4013 ICs are used. The 4013 is a dual type D flip-flop. Each section has 6 terminals: a data terminal marked D, a clock input marked C, an output marked Q, the complement of the output marked $\overline{Q}$ (pronounced not Q), and set and reset terminals. Data is transferred from the input D to output Q on the positive transition of the clock, provided that both the set and reset pins are low. With a high on the reset pin, the Q output is zero, and the $\overline{Q}$ output is high regardless of clock status.

Those of you who have constructed the "contest keyer" by WA4KUO will recognize the dot-dash generator used in this keyboard. The CMOS 4027 is a dual J-K flip-flop equivalent to the TTL 7473. The J-K flip-flop is similar to the type D flip-flop, except that it has two input terminals labeled J and K. The 4027 also flip-flops on the positive transition of the clock. The J-K flip-flop is useful in this application because, with relatively simple connections, it can be made to toggle with clock transitions.

Logic gates OR, AND, NOR, and NAND behave just as their names would suggest. OR gates and AND gates have two or more inputs and normally have only one output. In the case of an OR gate, a high on any input terminal will produce a high at the output terminal. With the AND gate, all of the input terminals must be high in order to obtain an output. Then, with the NOR and the NAND, the operation is simply reversed.

The inverter is another useful logical device. It has one output and one input, and they always complement each other. The 4049 has six inverters in one chip.

Two 40105 4-bit chips are used to make up an 8-bit first-in, first-out (FIFO) memory. This provides 8 input data terminals and 8 output terminals. A binary code word of 8 digits is loaded into the FIFO each time that the strobe pin receives a positive pulse. The array will hold 16 words. Within a few nanoseconds after loading, code words bubble through the memory and queue up in order at the output terminals. When the output data is stable, a *data out ready* (DOR) flag goes high. Binary words can be clocked out of the memory by applying a negative-going pulse to the shift-out (SO) terminals. Loading is completely independent of the output. By using the FIFO as a buffer between the input keyboard and the reading logic, the operator is free to type at any speed. If he types below the output clock speed, the output will follow the hesitating typing strokes. If the operator types faster then the clock speed, output will be a smooth continuous stream. Of course, since the memory will only hold 16 binary words, the operator cannot go more than 16 letters ahead of the reading logic or some of the characters will be lost.

Two 4035 chips are used to make an 8-bit shift register which also has 8 input and 8 output terminals. The shift register operates in the parallel mode as well

as in the serial mode. With the parallel/series (P/S) control high, 8-bit words are parallel loaded into the register clock. Data at inputs are transferred to the outputs each time the clock is pulsed. With the P/S control low, digits are shifted serially toward the right with each positive-going clock transition. The shift register is also equipped with a truth/complement (T/C) control so that an inverted output can be obtained. That is, all of the outputs will be exactly opposite to the corresponding inputs. Thus, if the serial input terminals (J-K) are made permanently high, zeros will be clocked into the shift-register output. These zeros migrate toward the final output terminal with each positive-going clock pulse.

Binary-coded words are generated for each letter in the alphabet and special characters by a diode matrix in the keyboard. The circuit is simple, and examination of Fig. 1 will show that it is only the Morse code with a marker bit added to mark the end of the character. Once you recognize the pattern, assuming that you know the Morse code, you can wire up the matrix without referring to a diagram.

The buses K0-K7 are energized through 10k, ¼-Watt resistors from the positive terminal of the power supply. Keyboard keys ground out selected bits of the K0-K7 buses through diodes to form the 8-bit code words required for each character. As an example, the letter "A" would have the code word 00000110. Recall that the shift register inverts all digits. The inverted digits correspond to K7, K6, K5, K4, K3, K2, K1, K0, respectively.

In the Morse code, there are more dots than there are dashes; therefore, in order to minimize the number of diodes, one diode is used to generate each dash. Read the code word from right to left: "Dit, dah, marker." Meaningful digits are followed by a string of filler zeros.

For a closer look at the system, refer to Figs. 2 and 3 which show the general schematic and its companion timing diagram. The diagram assumes that the operator has turned on power and set the master clock to operate at a selected speed. At some random time later, he has typed the letters "AE" followed by a word space, then the letter "T" at a speed greater than the corresponding clock speed. After power has been turned on, the master clock runs at a frequency set by the operator. The instant that a key is struck is a random event with respect to the clock output. The FIFO is very fast and responds within nanoseconds after the operator strikes a key on the keyboard. The code words (one 8-bit word for each character) bubble through to the output terminals of the FIFO, queuing up in order. As soon as data is stable, the data out ready (DOR) goes high. Since there are two FIFO chips involved, the two DOR signals are combined by AND gate U8D into a single signal. This high passes through OR gate U7C and on the next positive transition of the master clock output causes U12B to flip, thereby starting the dot generator in synchronism with the master clock. (I learned the hard way that this flip-flop 12B was needed. Without it, sometimes the first syllable of a letter would be cut short or missed completely. The addition of the 12th IC had a bonus. The "Q" of 12B gives a signal to provide automatic receive/transmit switching.)

The dot generator, U6A, is clocked by divide-by-2 flip-flop U12A, which runs at one-half clock frequency. The combination of U12A and U12B ensures that the dots will have the

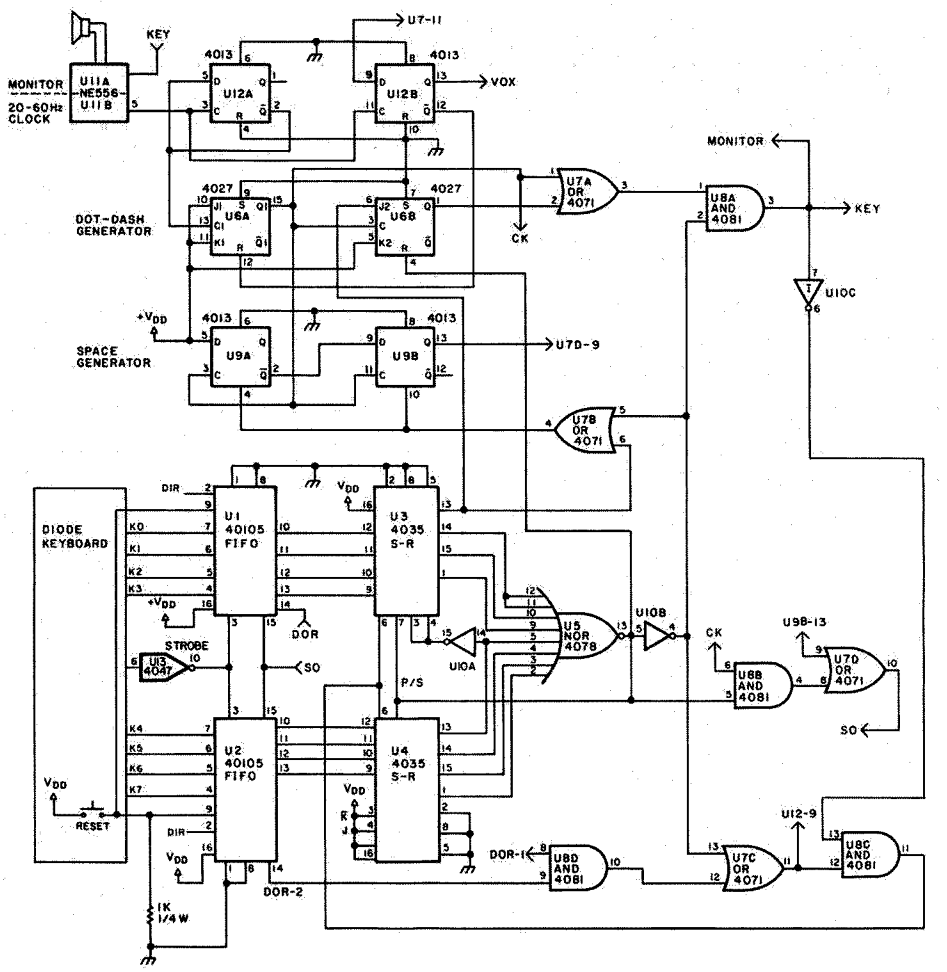

Fig. 2. CMOS Morse encoder schematic. U1, U2—40105 FIFO. U3, U4—4035 shift register. U5—4078 8-input NOR gate. U6—4027 dual J-K flip-flop. U7—4017 quad OR gate. U8—4081 quad AND gate. proper phase relationship with respect to the random loading of the FIFO.

Observe that the positive transition from DOR is passed through AND gate U8C to provide a positive-going clock pulse to clock the shift registers via pins 6-6. This causes the parallel-load feature to function because terminals 7-7 of the shift registers are already high (parallel mode) since at the time of starting, the outputs of the shift registers were all zero. Therefore, NOR gate U5 would have a high output.

Remember that the dot generator runs continuously once it is turned on by the synchronizer flip-flop. Each dot represents one time unit. This is also the fundamental time unit for dashes and spaces. The "CK" clock signal is generated by U6A, which is shown as line 6 of the timing diagram, Fig. 3. When required, U5 and U10B will silence the key by controlling pin 2 of AND gate U8A. Flip-flop U6B goes into operation any time that a dash is required. Examination of the timing diagram will show that both the dot generator and the dash generator are divide-by-2 counters. The OR gate, U7A, combines these outputs to produce a dash whenever U6B is active. Flip-flop U6B is turned off and on by commands from pin 13 of U3.

In the case of the letter "A", the first digit presented to terminal 13 is a zero. Consequently, the dash generator is restrained because there is a zero on the "J" input of U6B. Pin 2 of AND gate U8A is high because the signal from inverter U10B is the complement of NOR gate U5 output and all characters (except the word space) will have at least one "high" at the inputs of U5. The dot generated by U6A will be passed on to the keying circuit

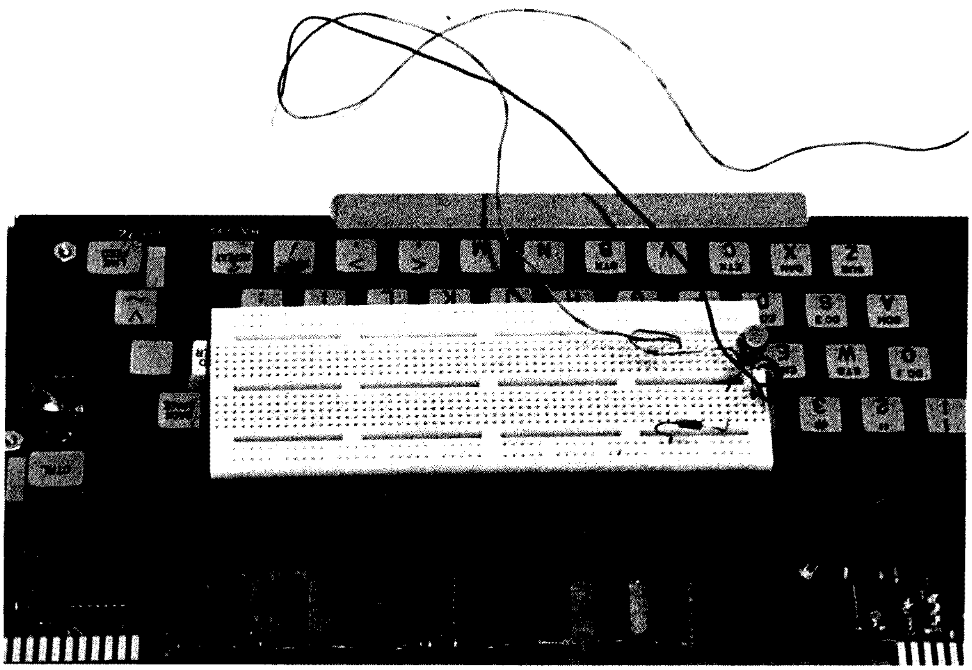

Photo B. A surplus NPN transistor, two current-limiting resistors, and an LED make a breadboard logic probe to debug circuit. Discrete components (lower right) are used for the clock and sidetone monitor.

through gates U7A and U8A. On the falling edge of the dot, the shift registers see a positive-going pulse on terminals 6-6 through AND gate U8C after it is inverted by U10C. This clocks the shift register one position to the right. Note that the shift register is in the serial mode because of the low on P/S. The next digit at terminal 13 of U3 is a one, representing the dash of the "A". This activates dash generator U6B, causing a dash to be dispatched. (See lines 6, 7, and 8 of Fig. 3.) On the falling edge of the dash, the shift register is pulsed again and another high moves to terminal 13 of U3. At this instant, all of the inputs to NOR gate 5 are low. This makes U5 output high and silences the key by causing pin 2 at U8A to be low. U5 output also resets dash generator U6B, changes the signal on P/S from high to low in preparation for a new character, and, at the same time, AND gate U8B is set up so that it will pass the next pulse from the dot generator.

The key is silent because of the low on pin 2 of U8A. The next pulse from the dot generator (see line 6, Fig. 3) is passed through U7D to shift out the next character. On the falling edge of the SO pulse, the FIFO dumps the old character and replaces it with a new one. During the dumping process, the DOR flag dips momentarily. This logic function is internal to the FIFO and the pulse is of only a few nanoseconds duration. (This is the only pulse in the system that is too short to be seen with a simple LED logic probe.) The short pulse is used to clock the shift register and parallel load the new character via gates U7C and U8C. This is more easily understood by referring to lines 13-15 of Fig. 3. This pulse is not to scale but illustrates the phase relationships. The process of dumping the old character and loading a new letter into the shift register has had the effect of silencing one dot. The dot requires one time unit; this, with the intervening spaces on either side, makes a total of 3, as is required by exact code for the inter-letter space. Some keyboards silence a "T", but this is not precise code because the "T" is 3 time units long, which, when added to the two intervening space units, totals 5 time units.

To continue the example, the letter "E" is dispatched next. Action would be similar to that described for the "A". The main difference is that following the "E" there is a word space. The code word for a word space is 00000000. With this code word loaded into the shift register, the key is silenced, as was the case with the inter-letter space, but pin 13 of U3 is also zero and this drops the reset signal of the space generator on U9. This is a mini shift register which counts the word space. Refer to the timing diagram and note that it has the effect of silencing a total of three dots. These dots plus the four intervening spaces total 7, as Mr. Morse specified for the word space.

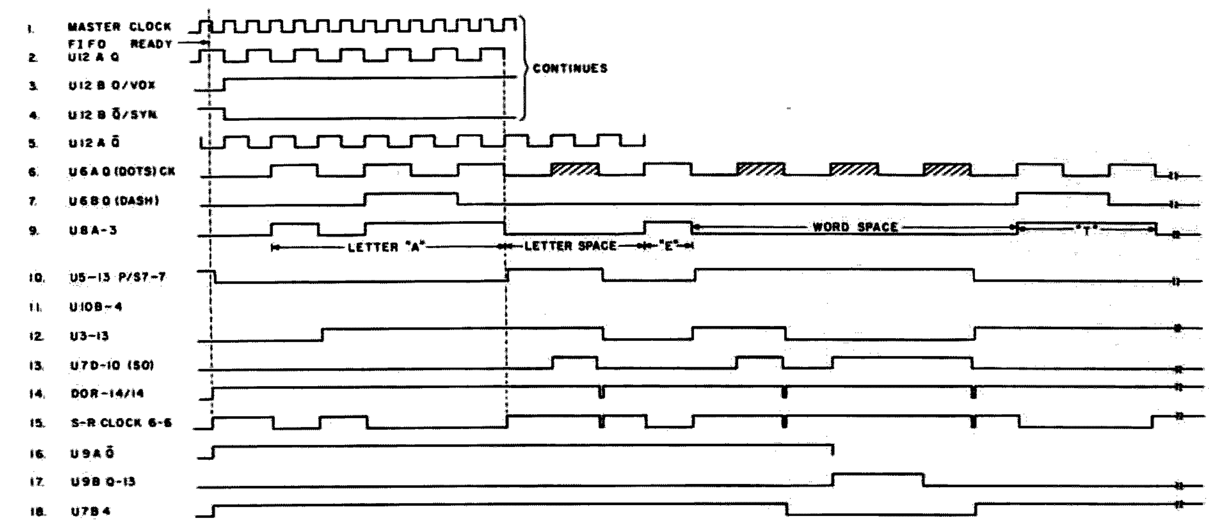

Fig. 3. Timing diagram.

The timing diagram shows the remaining letter "T" of the example. This is for illustration only and will not be described.

Circuit details for the sidetone oscillator, master clock, and the strobe have not been shown on the schematic because these are readily available from a number of existing publications. Manufacturers will supply chip specification sheets with this information.

The master clock and the sidetone oscillator (U11) are made from an NE556, which is simply two 555 timers in a single DIP package. A variety of capacitors and resistors are suitable. Just follow the graphs in the specification sheets. The master clock should have its frequency adjustable between 20 and 60 Hz for a speed range of about 5 to 50 wpm.

The sidetone oscillator can be made variable if desired. I used a fixed tone of about 440 Hz, which is the musical note "A". My rig has a sidetone oscillator, so I installed a switch to silence the monitor speaker while on the air. When not used for communications, the keyboard makes an excellent code teaching aid.

An additional switch can be installed to have a "send-store" feature. By stopping the master clock, the FIFO can be preloaded. A storage of sixteen characters is too short for anything more than a CQ. However, for those who would choose to have a longer message, the Fairchild FIFO 3351 is an excellent choice and holds 40 characters. One 3351 can be substituted for the two 40105 4-bit chips. Additional 40105 chips can also be cascaded to provide more storage.

A master reset button is needed for the FIFOs. Just after power up, random noise is loaded into the FIFOs, and, unless the M-R button is used, you will have a hard time recognizing the language that will be dispatched.

The choice of power supplies is almost unlimited. The CMOS and the NE556 can use anything between 5 and 15 volts. On my keyboard, I used a 50¢ surplus 6-volt, 200 mA calculator adapter. In order to improve the tone of the monitor, I did add a 25¢ electrolytic capacitor and a couple of resistors to provide filtering. To my surprise, even unfiltered full-wave dc can be used for the CMOS and still work. It must be that some of the claims about noise immunity by CMOS are valid.

As the numbering might suggest, U13 is an afterthought. At first I was determined to make a one-shot from the spare inverter gates in U10. According to RCA's ICAN 6267, three inverter gates will make a one-shot. The circuit worked most of the time, but occasionally a double pulse would be triggered, causing two letters to be loaded for one key stroke. I took the easy way out and cook-booked a 4047 one-shot and selected a capacitor/resistor combination to make a 2 millisecond pulse. This is a very versatile chip and does a good job of debouncing; it interlocks the keys so that only one letter will be dispatched even though two keys are struck simultaneously. This circuit will ignore all other strokes until keys are completely released.

The one-shot strobe (4047) is triggered by "wire-ORing" through diodes. The lower right of Fig. 1 shows this circuit. Note tht only buses K1, K2, K3, K4, and K5 are monitored. This is sufficient to cover all characters except the word space. A separate switch is used for the word space. The 4047 is connected to fire on a negative-going pulse which is obtained through 2 diodes in series for the normal characters and through a switch for the word space.

Experience with my Swan 700 CX has taught me that it eats expensive PNP transistors like a feathered swan eats corn. I took the coward's approach and used relays for both the VOX and key functions. This works very well except that if someday I am to give the "bionic brass pounder," WB2ZDF, his 1000 wpm, I may be forced to use a transistor. Is he kidding about 1000 wpm? Maybe not, or at least something that will approach that figure. Although no one can type 1000 wpm, a RAM can be interfaced in between the keyboard and the FIFOs to provide burst sending. Then, with the video readers, very high speed should be possible. This raises an interesting question. If TTL is on the verge of obsolescence, how about the RTTY bandwidth hog?

Parts for the final circuit cost about $40 (this does not include parts invested in the prototype which have been returned to the junk box). It does include

$10 for a surplus computer keyboard. This keyboard had good quality reed switches and a fiberglass PC board. None of the circuits on the PC board were salvaged but were removed from the old fiberglass board by using a wide-flame burner on a propane torch and a wood chisel. Holes for the diodes and the ICs were quickly drilled by using a standard piece of perforated board as a template and a Dremel tool. Interconnections were made with point-to-point wiring using standard wire-wrap wire. I use solder-tail sockets rather than conventional wire-wrap sockets because the long pins give my bifocals fits. A wire-wrap tool conveniently fastens connections to the solder-tail pins of the sockets and these can be quickly secured with a small dab of solder. This approach was used for all chips except No. 13. I ran out of sockets, so I simply wired this rascal in place. It worked so well that on the next circuit I build, I will not waste time with the sockets except for the two FIFOs. These are needed to provide a quick disconnect to simplify wire checking.

With 13 ICs, one can expect to make a few wiring errors. These can be readily detected by using a simple homemade logic probe that will cost less than $1.00. My breadboard probe is shown in Photo B parked on top of the keyboard. It is simply an LED driven by a small surplus NPN transistor with a length of No. 22 wire as a probe. By setting the clock at 5 wpm, the waveforms shown in Fig. 3 can be observed by simply watching the LED and counting flashes.

Should you decide to build a keyboard, be sure you understand the timing diagram. It is the key to troubleshooting. Also, recheck pin numbers against the IC manufacturer's specification sheet. Standardization is good, but there are some variations and it is possible that a typographical error exists. However, the diagram has been checked and rechecked to prevent the latter possibility.

The error signal has 8 time units; thus, it can be used as an aid in calibration: wpm = 192/T, where T = seconds (stopwatch) required to send 10 error signals.

A case was constructed from standard heating and ventilating sheet metal. While this is not as beautiful as some store-bought equipment, it is adequate.

If you are still not convinced that diodes are beautiful, you can use an ASCII keyboard, or, for that matter, any keyboard with an oddball code, as long as it does not exceed 8 bits. You can even use your home computer. An EPROM

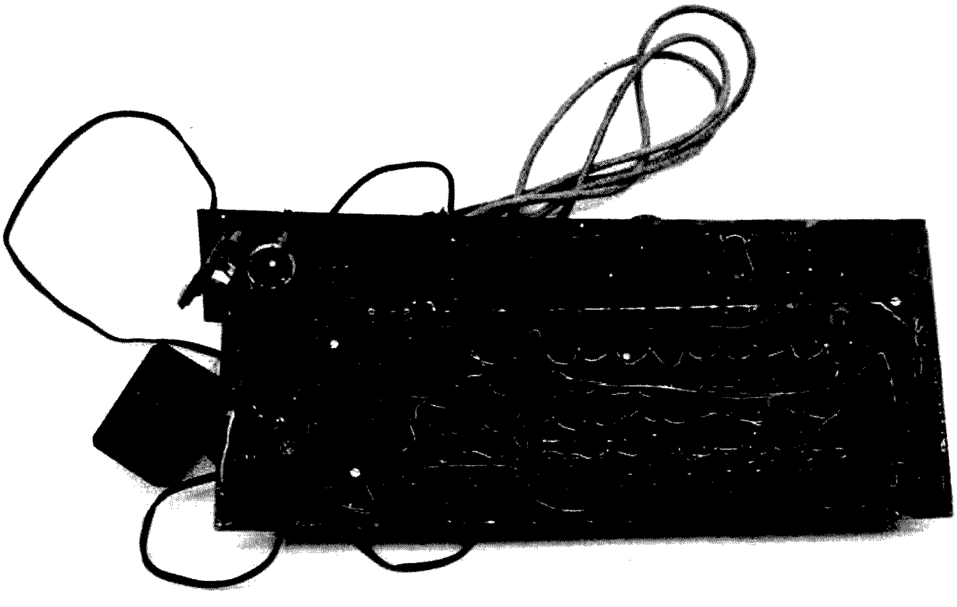

Photo C. This photo shows point-to-point wiring using wire-wrap wire for ICs and #22 telephone wire for keys and diode matrix buses.

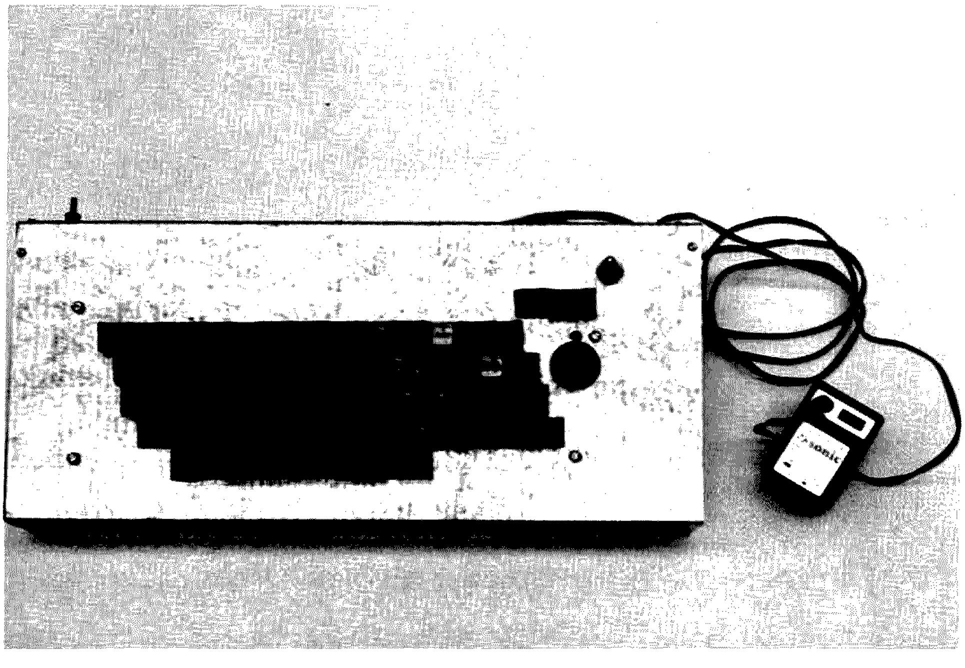

Photo D. Finished keyboard with surplus calculator power supply at right.

can be used to interface between the keyboard and the FIFOs.

In addition to all of the hams mentioned in the text and the references, I am indebted to the sales reps and tech-service engineers of both RCA and Fairchild. They patiently answered my numerous and sometimes frivolous questions. They not only made it possible for me to build a keyboard, but also helped me in my job as a power engineer to apply integrated circuits to industrial applications.

After a 30-year recess in radio, my straight-key sending was even worse than it was during World War II when I frequently would be interrogated with "INT LF" (modern translation, QLF?). Now, with my keyboard, I, too, can make good CW music and the high-speed boys will talk to me. Perhaps after a few more keyboards are on the air, the average QSO can be raised to 30 wpm.■

The Cure for Migraines

—a low-pass CW filter

In most receivers, the groundwork has already been laid.

Many hams copy CW by using an SSB receiver with an outboard CW filter consisting of 88-mH toroids or active filters, to obtain very narrow bandwidths and a beat note of about 1000 Hertz. Some have found that a couple of hours of this type of operating will bring on something resembling a migraine headache and a strong desire to go work SSB up the band.

A lower beat note and a bandwidth of a few hundred Hertz appear to alleviate CW fatigue. The lower tone is softer to the ear and a somewhat wider bandwidth allows the signal to be moved around slightly in the passband, which helps to avoid monotony.

One advantage of this approach is that one side of the needed filter response is already there in most receivers. The low frequency side of a typical communications receiver might appear as in Fig. 1. The audio section is designed to attenuate the very low audio frequencies, usually with the 3-dB point around 300 Hertz.

This allows you to build a simple, low-pass filter to get the desired attenuation on the high-frequency side. The filter is shown in Fig. 2. The .176-H inductors are made from two 88-mH toroids connected in series. It plugs into the speaker output, requires no power, uses common components, and will fit easily inside a small minibox. Its response is shown in Fig. 3.

Combined response is shown in Fig. 4. Bandwidth is about 300 Hertz at the 3-dB points, allowing for some variation of tone (and drift). There appears to be less ringing with this approach, as compared with one narrow filter.

This filter may solve your headache. See you on the low end, OM.■

An 8080 Repeater Control System

—part I: an overview

This setup is the definition of "modern."

Robert Glaser N3IC
3922 Algiers Road
Randallstown MD 21133

When told I was going to install a microprocessor on our repeater as the controlling element, some felt, "A microprocessor on the repeater—what for?" After explaining that I would not add anything as complex as a microcomputer to the repeater unless there was good reason to do so, there was no vocal opposition. I suspect that it was not until the control system was placed into operation that everyone became in favor of it. The reason I mention these facts immediately is that a quick first impression of the control system could very well be that the system is too complicated for the resultant benefits. In fact, the opposite is true. The system is indeed much more complicated than what is normally encountered in similar applications. However, the operations it can perform are much greater than would be found were the benefits only proportionate to the system complexity. With an intelligent controller, functions can be done which could not possibly be done otherwise with a reasonable amount of hardware.

Originally, the major function of the control system, and the reason for implementation with a microprocessor, was to provide many on/off output lines controllable through multiple digit decoding of touchtone™ signals. The existing system, consisting mostly of relays, was capable of at

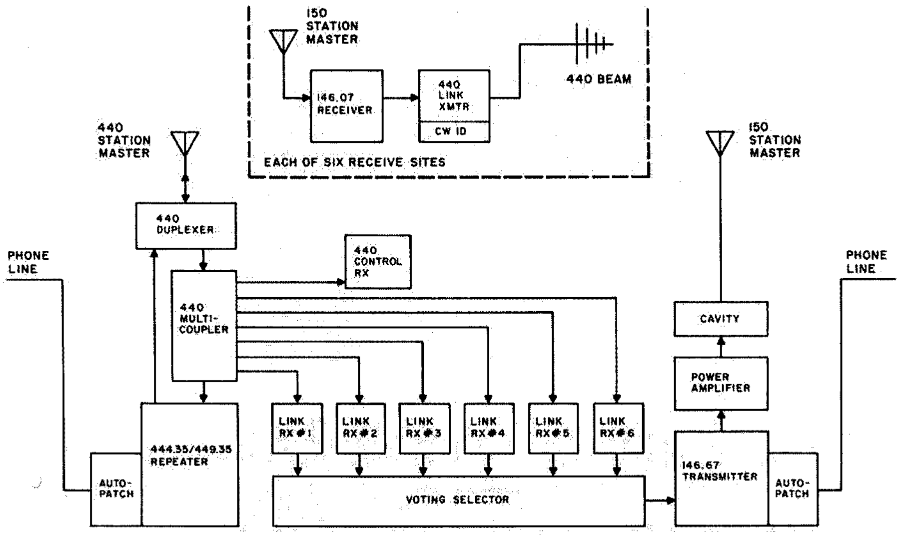

Fig. 1. WR3AFM equipment.

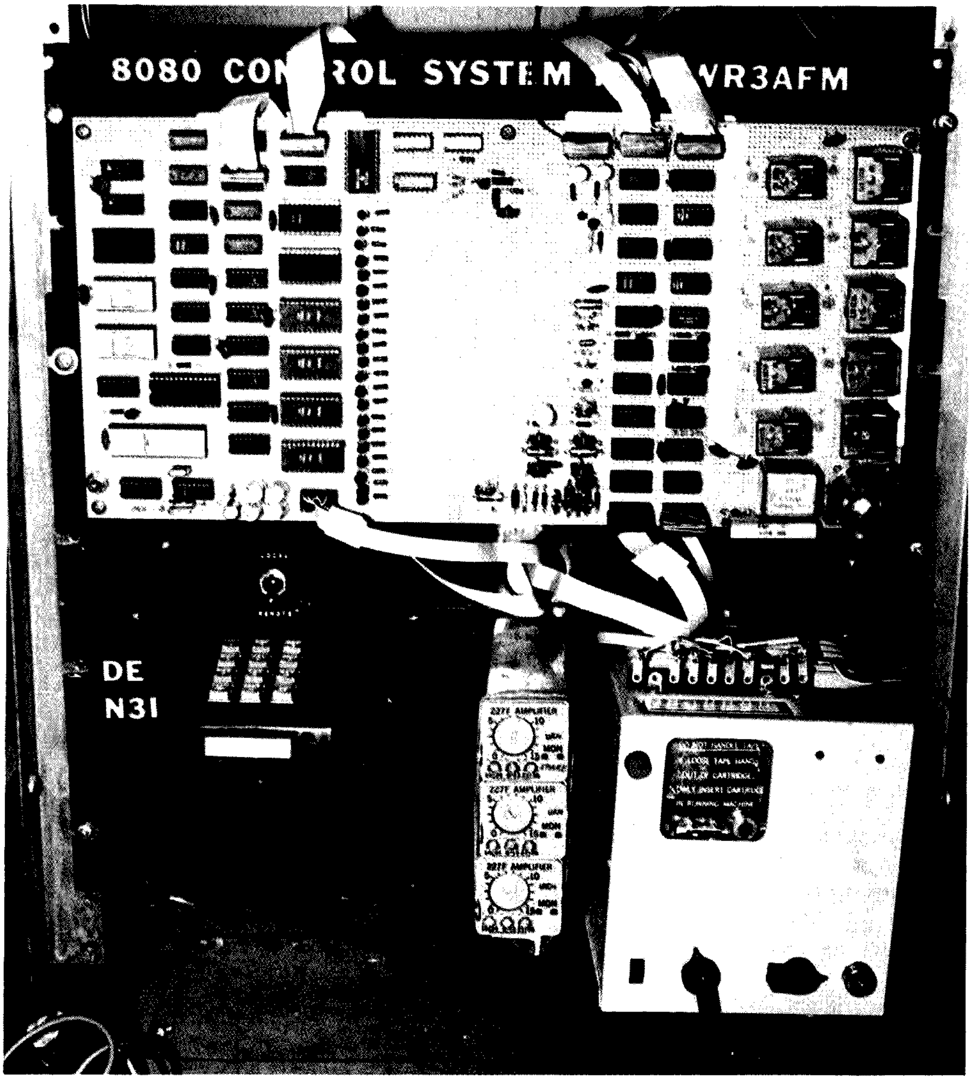
most six functions. We required several dozen functions, and simple expansion of the relay system would have made the repeater look and sound like a telephone company central office. After the new system was finished, the simple output functions took a back seat to the innovations which were not possible before.

In order to understand what the 8080 control system does, a brief description of the Baltimore Amateur Radio Club's repeater (WR3AFM) is necessary. Fig. 1 shows a block diagram of the repeater. There are actually two repeaters: a two meter repeater and a 440 MHz repeater. The 440 repeater is a simple duplexed one. It has an autopatch independent of the rest of the system. The two meter repeater is a multiple split site repeater. The two meter transmitter is located at the site of the 440 repeater. Spread around the city are up to six receive sites. Each receive site receives signals on the two meter input frequency and retransmits them on a 440 link frequency to the transmitter site. At the transmit site, signals are received from each of the links. Each link receiver feeds a voting selector, which continuously evaluates the signal-to-noise ratio of each signal and passes the best one on to the transmitter. The two meter repeater also has an autopatch. The repeaters can be controlled via the two meter repeater autopatch telephone line or a 440 receiver reserved for control. All told, there are eight 440 receivers; off the receive port of the 440 duplexer is a 440 multicoupler which splits and boosts the signals received from the 440 repeater antenna. As can be seen, we obtain maximum utilization (eight receivers and one transmitter) from the 440 antenna on the top of the tower (400 feet high)!



Control system connected to repeater.

The voting selector can be directed to pass only one of its inputs to the transmitter, or to ignore some of its input receivers. This is a major function of the control system. As our repeater gradually expanded, it became more difficult to diagnose problems. A week would go by before we even realized that one of the receive sites was inoperative. With the new system, it is easy to check all sites by commanding the voter to pass each receiver one at a time. During the summer months, we are plagued with skip signals from users of the two nearest repeaters on the same frequency: Hazelton PA and Trenton NJ. At times, our repeater is unusable due to constantly timing out from the extraneous signals. We can now command the voter to ignore our northeastern receiver, from which most of the interference arrives. These two basic functions provided the impetus for the construction of the 8080 system.

The system has other important functions. It allows the two meter and 440 repeaters to be linked when needed. A prerecorded tape loop can be activated on request, giving information about the repeater and the club. A feature is provided to test touchtone pads—the repeater tells the user in Morse code what it received. The processor controls the autopatch. Instead of the normal system, it gets the requested telephone number from the user and redials the number into the telephone system. If the proper number of digits is not received, it will not even access the telephone line. Single-digit codes permit dialing of emergency numbers. Non-collect toll calls are impossible. There

Using the System

The following text, after suitable modifications, is intended to be distributed to users of repeater systems using the 8080 control system. Use of the processor functions and the autopatch are described.

WR3AFM is now controlled by an 8080 microprocessor. The processor permits flexibility in the system as well as many functions which could not reasonably be implemented without a processor. There are five CW IDs; four are permanently stored, and one is remotely programmable via a touchtone pad. Any of the five IDs may be selected, or, as is often the case, the different IDs may be made to cycle. The programmable ID allows meeting announcements and anything else that could be useful to be placed on the repeater.

For testing and diagnosis, each of the individual receive sites on 07/67 may be either disabled or forced on through the voting selector. There are several modes of accessing the control system, so it is possible for control stations to work on the system without interfering with repeater users. For most functions, the 8080 responds to correct commands with an "R" in CW, so when "R"s are heard on 67 this means that someone is commanding it. Under such circumstances, be slow to pick up transmissions in case the control operator has any requests; if none are made, feel free to continue using the repeater and ignore the "R"s.

For those interested in the size of the 8080 system, it currently has about 2K of program in ROM, 256 bytes of RAM, seven eight-bit output ports, and three eight-bit input ports. The control program is about 1300 lines long, and the hardware consists of 57 integrated circuits.

The processor makes possible the redialing of telephone numbers, the virtual elimination of incorrect dialing for autopatches, and the prevention of toll-charge telephone calls. In addition to the control functions and the autopatch, the processor has five codes available for general use which are accessible via 146.07. Any ideas for additional functions will certainly be entertained. For each of the codes, it is necessary for the first digit to be held at least one full second. It doesn't hurt to hold any tone longer than required. With this in mind, here are the various codes:

1#1—Links the 146.07/146.67 repeater with the 444.35/449.35 repeater. The repeater answers with an "R" if the function is accepted. The linkup will remain up indefinitely until knocked down with a *. Signals on 146.07 will come out on both repeaters, and signals on 444.35 will come out on both repeaters. When disconnected, the repeater responds with an "R" as well. The intention of this function is for calling someone on the other repeater, not for extended rag chewing on both repeaters simultaneously. When transmitting on 444.35, 1#1 will also link up the repeaters. This function on the 440 end is not controlled by the microprocessor, and it does not acknowledge with an "R". The * on 444.35 will kill the linkup if it was initiated on 444.35; alternatively, on the 440 end the linkup will time out after three minutes. This is only true for linkups made from the 440 repeater. The two linkups are separate; if linked on 146.07 they must be killed on that frequency, and if linked on 444.35 they must be killed on that frequency.

2#2—Initiates a prerecorded tape message giving information about the repeater. The tape will disable itself upon completion.

3#3—Disables the blocking of touchtones. Any tones sent after the 3#3 before the carrier is dropped will not be blocked. Normally, upon recognition of valid tones, the repeater mutes them. This is done to protect the ears of those of us who monitor often. It is done on a tone-by-tone basis to facilitate diagnosing problems, since you can hear a short blip for every digit and can tell how many tones were sent. For those hams with selective call decoders, it is necessary for the tones to pass unimpeded, which is the reason for this function. If only short tones are required, the selective call function need not be used, as the repeater does not initiate tone blocking until a valid tone of about one second is received. This is to prevent blocking of voices.

4#4—Touchtone test. Any digits sent after the 4#4 before the carrier is dropped will be sent in Morse to tell the user what the repeater decoded the digits as. Any sequence up to 24 digits can be accommodated.

5#5—If preceded by a 4#4 test, will repeat what the 4#4 sent. If preceded by an autopatch, the telephone number entered will be sent in Morse. If an autopatch attempt fails, 5#5 will show what the number requested was (if the autopatch code was accepted). If, after making an autopatch, you wish to clear your telephone number from the machine, simply do a 4#4.

NOTE: The functions 1#1 through 5#5 are intended for use by anyone, club member or not. The autopatch is restricted to club members and transients. When performing any of these commands, be certain to identify your station first. The functions are there to be used, but not abused. This is somewhat of an experiment in the hope that our repeater users will use these functions wisely. We hope to be able to continue this free access. Should it become necessary, any of the functions may be disabled by remote control. Please do not force us to deactivate them.

are several different CW identifications which may be selected, and special IDs can be loaded in minutes remotely. For a number of years, we have had a reprogrammable CW identifier (*73 Magazine*, April, 1976). It was a great success, and the ability to program an ID remotely makes it more useful. Any of the functions can be disabled, and, of course, the repeaters can be turned off if necessary. A complete explanation of the user codes appears elsewhere in this article. A sample of what can be placed on the tape message loop is given. A complete description of the control functions, "Controlling the System," also appears elsewhere. It is more difficult to control the system than with a simple arrangement, but many times it is not even necessary to enter the control mode and forcefully disable functions. Merely by transmitting on the control frequency, everyone else loses access to the touchtone decoder. This is of great use when some user decides that he will execute some function without identifying himself, as required by FCC regulations. A simple transmission on the control frequency removes his access to the system, and it is not even obvious to those listening. With any amount of luck, these individuals adjust their touchtone pads attempting to bring up a function and throw their pads away in disgust after being unsuccessful.

We have been quite pleased with the overall operation of the control system. The user codes have given the repeater users some involvement with the repeater, and, after the initial adaptation period, general user sentiment has been quite positive. Although the control system is fairly complex, the reliability so far has been good. In the first two months of operation, the system crashed twice. In the software world, a computer "crash" refers to the occurrence of some error which causes a computer to ignore operator commands, necessitating a hardware restart. I added an error detection/recovery routine to the system, and there have been no crashes since. There have been no hardware failures.

In the following sections, I will show how you can duplicate the system, how the hardware and software functions are distributed, what the hardware components are, and provide explanations of how to use and control the

Autopatch Access Procedure

The following procedure is recommended for accessing the autopatch.

1) "N3ABC autopatch"
2) Send the autopatch code and the telephone number in one transmission. Remember to hold the first tone one second. It is imperative that the carrier continue throughout the entire operation of all ten digits. Upon the release of carrier, the repeater will determine if your number is valid. The number is valid if any one of the following conditions is met: exactly one digit which corresponds to a single digit emergency number; exactly seven digits, the first digit not a 1; exactly eight digits, the first number a 0; exactly eleven digits, the first number a 0. If the number is invalid, nothing will happen. It will act as though no autopatch code had been entered, and it is not necessary to send the knockdown digit. If the number is valid, the repeater will bring up the telephone line and redial your number.
3) After the number has been dialed, and the line has clicked over, "N3ABC".
4) Conversation
5) "N3ABC clear with John Doe at 12:37 PM on August 12."
6) Knockdown code. If the "beep" is heard, the patch has been killed.
7) "WR3AFM this is N3ABC clear."

If you have problems, remember the 5#5 code.

The repeater now has several single-digit special numbers. Make a note of these special codes:

2—Baltimore City Police
3—Baltimore City Transit and Traffic
4—Maryland State Police
5—Harbor Tunnel Information
6—Anne Arundel County Police
7—Coast Guard Search and Rescue
8—Baltimore County Police
9—Howard County Police

To use the single digit codes, send the autopatch code followed immediately by the single digit. The repeater will dial the proper number for you.

Half Duplex

The autopatch is half-duplex. This means that the audio from the telephone line is switched off when you push the PTT. This feature can be used to block obscene language, business communication, or whatever, if the called party gets carried away. However, "skip" or interfering signals also have the same effect. Therefore, it is not wise to initiate an autopatch under such conditions. If this problem occurs, remember that the party on the telephone can hear you perfectly—it is just that you cannot hear him whenever any signal is present on 146.07, be it yours or something else.

Autopatch Timer

The autopatch is to be used for short traffic only. A timer will automatically terminate the patch after three minutes. Once activated, the patch will stay up until terminated by the timer or the knockdown code. No kerchunking is needed to keep it up. Three minutes is more than adequate for most autopatches. However, sometimes when in communication with police regarding an emergency it is desirable to continue the autopatch past the three-minute limit. Because of this, the timer is automatically deactivated when a *single digit* emergency number is used. The patch will not time out for these calls. For normal calls, it is not possible to extend the three-minute limit. For all calls, think of what to say before calling.

Tape Massage Taxt
(Time: 2 minutes, 50 seconds)

Welcome to the Baltimore Amateur Radio Club's 07/67 repeater, WR3AFM. The transmitter is located at the old WBAL tower on Park Heights Ave., and drives a 250-Watt amplifier, though only a portion of that power reaches the antenna through about 500 feet of feedline. The repeater has receivers north of the beltway on Old Harford Road, at the WRBS tower near I-95 south and the beltway, downtown at 4000 North Charles Street, and at the QTH of K3VC and N3JC at the top of the Jones Falls Expressway. Each of these receivers drives a 440-MHz link transmitter. At the transmit site, there is a link receiver for each receive site. Each signal is fed to a voting selector, which continuously evaluates the signal-to-noise ratio of each receiver, the best of which goes to the transmitter. All of the repeater equipment is of the General Electric MASTR make.

At the transmit site, there is also a duplexed 440-MHz repeater, 444.35 in and 449.35 out.

You will note that a short click is heard after releasing your carrier. This signifies that the repeater timer has been reset, and leaves time for breakers. It is not necessary to let the repeater carrier drop. 07/67 has an autopatch, limited to travelers and club members, but open to anyone for emergency traffic.

The repeater is set up to block touchtone signals. After a long first tone of about one second, any further tones will be blocked from repeating, and only a short blip will be heard. There are several codes that anyone is welcome to use. One pound one links the 67 machine with the 440 repeater. To acknowledge that function, the repeater sends an "R" in Morse. The repeaters remain linked until a star is sent, again acknowledged with an "R". We do not desire to use this function for more than a calling mode. Two pound two gives this recorded message. Three pound three will disable the repeater's blocking function until the carrier is dropped, permitting the tones to be repeated. Any touchtone digits sent after four pound four will be verified in Morse after the carrier drop. Five pound five will repeat what was sent during a four pound four operation or the telephone number dialed during an autopatch, whichever was last.

The control system for the repeaters is an 8080-based microprocessor, which performs the various functions including multiple identifications, as well as redials telephone numbers for the autopatch.

The Baltimore Amateur Radio Club has another two meter repeater, 34/94, which is a duplexed repeater in the Towson area. We hope you enjoy the use of our repeaters, and would like to see you at our meetings on the first and third Wednesdays of the month at the Ames Methodist Church in Pikesville at 8:00 pm. Listen for interesting bulletins weekdays on 67 at 7:30 am and rebroadcast on 94 at 6:00 pm. Code practice can be heard Mondays at 9:00 pm on 34/94. Should you desire to contact the club, write the Baltimore Amateur Radio Club, PO Box 5344, Baltimore MD 21209.

system. The method of construction, a detailed circuit and program analysis, and some principles I learned in developing the project will be presented in subsequent parts.

Duplication

The 8080 control system can be duplicated for your repeater with few modifications. The control system supports some features of WR3AFM which may not be of use on an average repeater. If nothing but the basic user codes, the multiple IDs, the autopatch functions, and on/off control for a simple repeater is needed, the 8080 control system would still be worthwhile to construct. If the system is totally duplicated, and portions are left unconnected (due to having no voter, 440 repeater, etc.), the system will operate and leave room for expansion. Alternatively, the appropriate pieces could be left out easily. In either case, the program would remain the same. It may have codes which do nothing or do something different, but the program is the major work and is already done for you. If no changes are contemplated for the program, then it is not necessary to understand how it works. It is always informative to do so, but don't worry about it too much if you are not familiar with 8080 machine language. For those who wish to personalize the software, it can certainly

Feb - 1979

Controlling the System

The following text is intended for distribution to control operators of repeater systems utilizing the 8080 control system. The necessary codes will have to be changed.

The microprocessor control system is a complex but flexible and powerful system. It is of utmost importance to completely understand its operation before attempting to utilize it. Although at first the system may seem to be overly complicated, the structure of the control codes makes it easier to use than a first glance might show.

Basically, the system reads the output of the touchtone decoder to decipher the codes, and has 56 output lines which may be controlled by the proper input combinations. External to the processor itself is additional circuitry to perform the necessary functions, i.e., autopatch, remote base, control frequency repeat, and phone line control. User codes all operate on the outputs indirectly. The proper bits are set and reset to perform the desired function, but control codes are all direct changes of output lines which are assigned to control the various functions.

The basic decoding method used decodes three-digit codes. The first digit of the code must be held down for one second, or nothing will happen. After the release of the first digit, if three seconds elapse before another digit is received, the code will be canceled where it stands. After the release of the second tone, three seconds is likewise allowed to enter the third digit. During the time that the first tone exceeds the one second time period, and until the end of the digit sequence, the blocking relay will follow any valid touchtone signal. During an autopatch or remote base function, the blocking relay will follow the tones as well. At all other times the blocking relay is not activated. Due to this arrangement, in order to have voice signals blocked, the voice must be a valid touchtone signal for one second—certainly a rare if not impossible situation.

Telephone and Control Receiver Access

There are two modes for each of these devices: control and talk. The normal mode for both is control. For the control receiver, this means that the signal is not repeated on 67 but the control receiver grabs the touchtone decoder. The control receiver has highest priority, unless the control receiver touchtone bit is set, which effectively removes the control receiver from the system. If, while transmitting on the control frequency, a # is entered for five seconds, then the control receiver talk mode is entered. While in this mode, the control receiver is repeated on 67. The only way to exit this mode is to send a one-second * while on the control frequency. As long as the control receiver bit is not set, the control receiver always has the decoder. When in the non-talk mode, this allows control of repeater functions without bothering users of the repeater, except that they will not be able to access the touchtone decoder to make autopatches. For the telephone line, when a call-in is made, the mode is set to telephone control. You cannot hear anything. However, the touchtone decoder is listening only to the telephone line. In this manner, control can be exerted in the same way as with the control receiver. If you wish to hear the repeater on the phone line, a five-second # on the line will switch you out of the phone control mode, and the voter audio will be sent down the phone line when an incoming carrier is present. When a signal is present, it has the decoder, not the phone line. Otherwise, the phone line has the decoder. To return to the phone control mode, a * while on the telephone will do so, as will hanging up and redialing. If the telephone touchtone disable bit is set, it will be impossible to enter the phone control mode, and any touchtones received from the phone will be rejected.

Note that any of the three modes of control may be disabled: 150 input, control receiver, and telephone. *Beware:* If all bits are set, you go to the repeater and push the reset button (or wait for a power failure to reset it automatically). Naturally, it would be inconceivable to lock out all modes of control accidentally.

be done. If you do not have any support for the 8080, or for some other reason cannot program 2708 ROMs, I will provide the two ROMs for a cost of $50. Specify your choice for the following codes: 67#, 2*2, 9#5, 6*#, #*6, #48. The knockdown digit will be * unless requested otherwise. Codes may not start with whatever digit is chosen as the knockdown digit. Also specify the four IDs and the telephone numbers for the single-digit dialing. For obvious reasons, the above codes must be changed for each repeater.

This project is by no means a simple one, and it is not suitable for the beginner. Construction experience with integrated circuits and a basic understanding of the system are required. It is not an extremely difficult project as long as care is taken during assembly. Probably the most difficult part will be deciding how to interface a particular repeater to the system. The entire system can be constructed in one week (full-time) by a proficient builder. Do not shy away from the project if you have no prior experience with microprocessors. The "black box" approach is utilized, and detailed knowledge of the inner workings of microprocessors is not required. Total cost for the system is dependent upon how much peripheral equipment is available. The control system cost us about $225, exclusive of the touchtone decoder and pad, amplifiers, and tape loop.

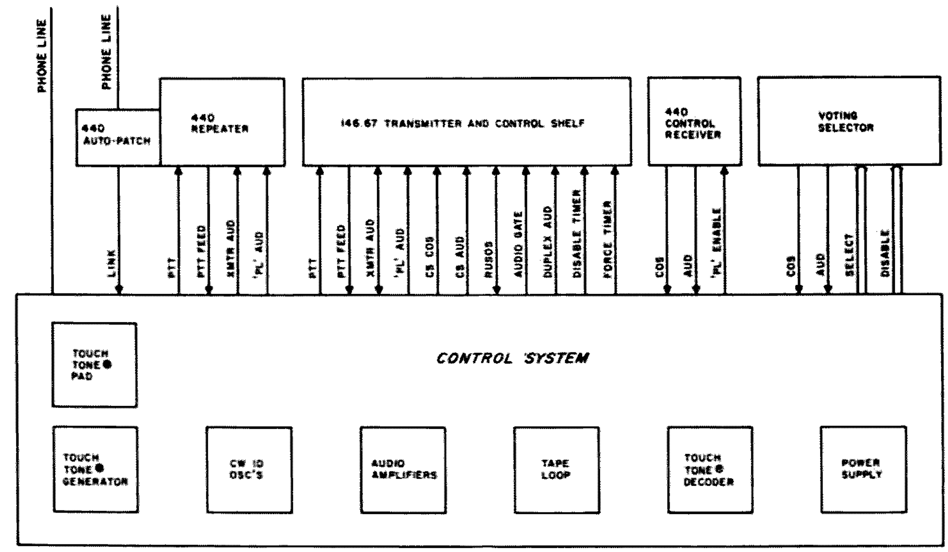


Fig. 2. Repeater/control system interface.

Hardware/Software Balance

Some of the control functions are implemented in software and some are implemented in special

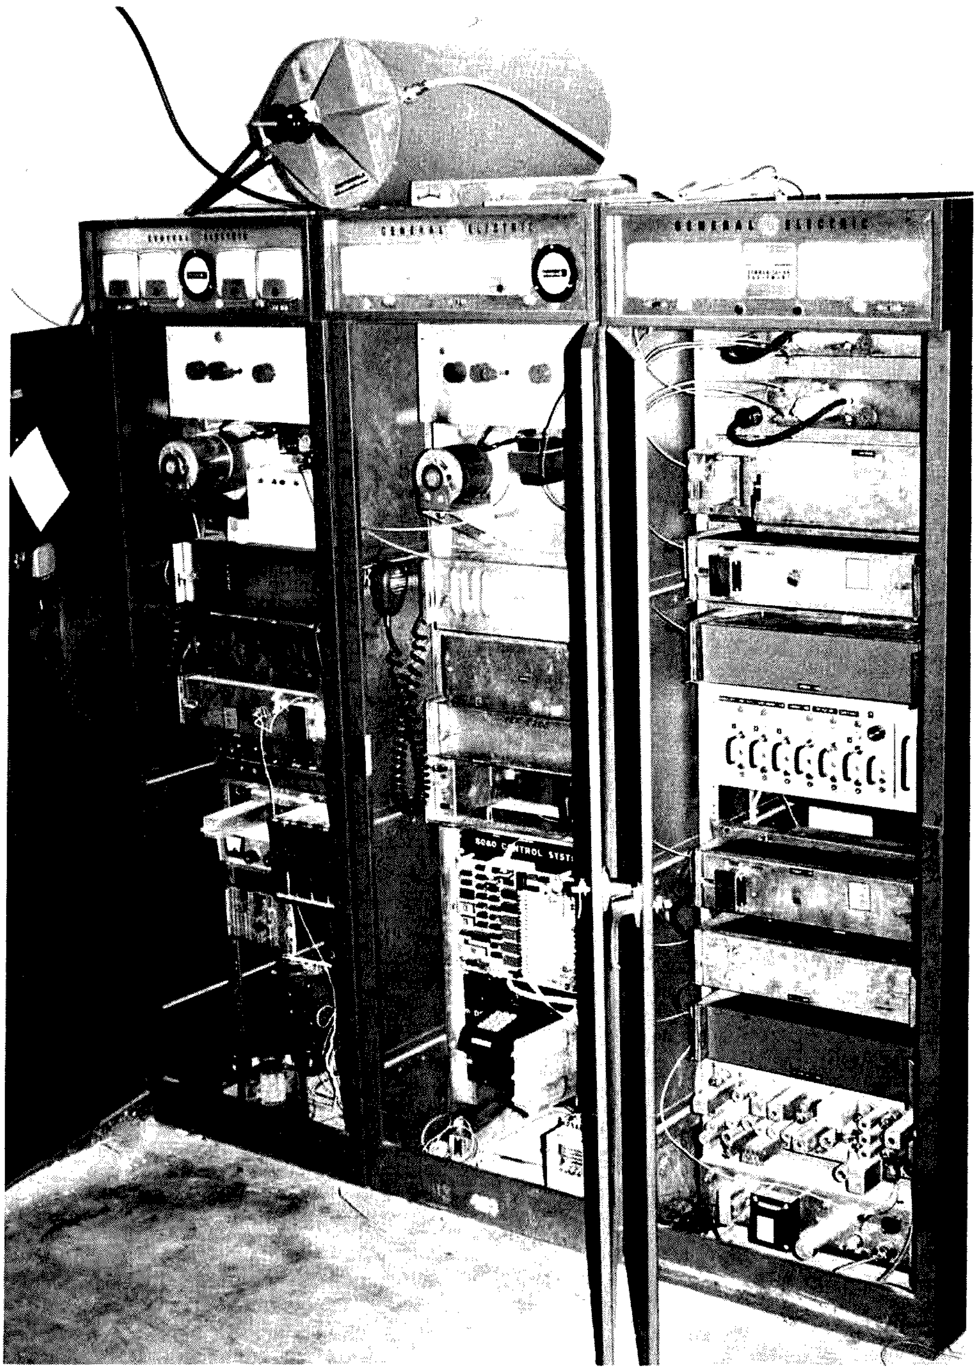
hardware. Deciding where to draw the line is an interesting problem. There are trade-offs which must be made. The major advantage of using a microprocessor is replacing hardware with software, so at first glance it may seem that everything that can be placed into software should be. However, I would rather add one flip-flop than add several hundred extra lines of program. Four years ago, I made the mistake of taking all possible hardware out of a system. My first attempt at computerizing WR3AFM started at that time when I constructed a system based on the 4004 CPU, a 4-bit machine. I designed the hardware, giving the software total control over the hardware. Everything was done with the software. At that time, being hardware oriented, I built the thing first and assumed that I would then write the program. The hardware functioned perfectly—unfortunately, I could not write the program. It could be done, but it was so complicated that it would have taken me several months of concentrated effort to accomplish the task. I effectively junked the project and am still trying to think up some possible use for the thing.

This time around I did not make the same mistake. There are four state flip-flops in the external hardware. These keep track of the autopatch, remote base, control receiver talk, and telephone control states. The processor does not know or need to know the current state to execute its functions. It basically acts as a CW identifier and a multiple digit decoder. It does keep track of many internal states, but these states are not needed until a function is called which needs them. The extra dozen ICs greatly simplify the software, and I believe that the hardware/software balance of this system is near optimal.

Hardware Description

The repeater block diagram shown in Fig. 1 was previously discussed. Fig. 2 shows how the control system interfaces with the repeater. Surely, each repeater will have to be reckoned with on an individual basis. Understanding how WR3AFM works should demonstrate how to interface the control system with any repeater.

The 146.07/146.67 MHz repeater is referred to as 150 and the 444.35/449.35 MHz repeater is referred to as either 440 or 450. The



WR3AFM. Left cabinet—444.35/449.35 repeater. Top to bottom: power amplifier, transmitter, receiver, control panel, autopatch circuitry. Center cabinet—146.67. Top to bottom: power amplifier, transmitter, control receiver, control shelf, 8080 control system. Right cabinet—link cabinet. Top to bottom: 440 multicouplers, power supply for receiver #6, 5 link receivers, voting selector. Tube receiver on bottom no longer in use. 146.67 pass cavity on top. 440 duplexer out of view in left cabinet.

User Codes

There are eight user codes. 1#1 links 67 and 449.35. The two repeaters remain linked until they are unlinked by a single *. The proper output line is automatically set and reset for the link and unlink commands. To tell the user that the link or unlink has been established, the repeater acknowledges with an "R" in Morse.

2#2 plays the prerecorded tape loop. Once it is started, there is no way to stop it short of shutting down the repeater.

3#3 is the disable blocking or selective call code. The blocking is disabled after the second three is received until the incoming carrier is dropped.

4#4 is the touchtone test function. Any tones up to a maximum of 24 will be played back on CW after carrier drop if preceded with the 4#4 code.

5#5 will repeat what was sent during a 4#4, or the telephone number requested in an autopatch, whichever was last.

67# is the autopatch code. In one transmission, the code plus the telephone number must be sent. The processor will not access the telephone line unless a valid telephone number is received. Normally this consists of exactly 7 digits, the first digit not a 1. Other valid numbers are 8 or 11 digits, with the first digit a 0 and the single digit codes. If the single digit code is correct, the proper emergency number will be found and sent. If an invalid number is attempted, nothing happens, exactly as if no autopatch attempt had been made. For valid numbers, the repeater will bring up the telephone line and redial the stored telephone number. This system prevents incorrect calls due to signal chopping which cause shotgunning of the touchtones (which result in more than 7 digits). When a single digit code is used, the three-minute timer is defeated automatically. If the 67# is sent by itself and the direct autopatch bit is set, then the repeater will bring up the telephone line and permit the user direct access to the telephone dialing system. This is not normally done, as it is not needed.

9#5 is the remote base code. The normal method is to use this by calling in on the phone line. However, nothing prevents its use on the air. All it does is connect the repeater to the phone lines, but it will not initiate a call. This is not strictly a user code, as the users should not know it, but there is no technical distinction between it and the other user codes. If the repeater times out during an autopatch or a remote base function, those functions will be canceled.

2*2 also performs the tape function. There is no distinction between this and the 2#2 except that the 2*2 is for control stations only. The two codes may be disabled separately. By using the 2*2 function, if it becomes necessary to disable 2#2, control operators may activate the tape upon request without needing to get into command mode and enable the 2#2 function.

In order to exert command on the repeater, it is necessary to enter the command mode. 6*# initiates the request. After entering this code, the carrier must be dropped. If the command is from the telephone line, the procedure may continue immediately. A confirmation code must be entered next. The confirm code is #*6. *Important:* Once the command code is issued, the system will wait for the confirm code forever. If no tone is given, the system will not be reset until it receives another touchtone. After the confirm code is entered, the carrier must be dropped again. Next, a single digit code is entered. If the single digit is a valid command, then the repeater will acknowledge with an "R". With the exception of three special single digit commands, the command mode is automatically left, and operation is again normal. A description of the single digit codes follows.

The system has five different messages. Four are permanently stored in the ROM. They are presently (1) "DE WR3AFM BARC," (2) "DE WR3AFM BALTIMORE," (3) "73 DE WR3AFM," and (4) "DE WR3AFM BALTO ARC." In addition to these four, there is a fifth which may be programmed through another command.

Commands one through five select that number ID to be used always. Command six rotates through 1,2,3,4,1,2,3,4, etc., each time the repeater identifies. Command seven rotates through all five IDs.

Command nine resets all functions to the normal state. Normal is both repeaters enabled, ID #1 selected, and all other outputs ungrounded. This is the same thing as pushing the reset button on the control system.

Command * resets the ID timer. The next time one of the repeaters is kerchunked, that repeater will identify. A word here about the timing of IDs is in order. In the rest mode, as after the * command, the first repeater used identifies. If, in the subsequent three minutes, one or both of the repeaters is used, then one or both of the repeaters will identify three minutes later. In this manner, the repeater is a "tail-ender," and always gets in the last word (something that is very difficult for one of us mortals to do on the repeater).

Commands 8, 0, and # are the commands which do not exit the command mode immediately. Command eight is the ID load command. This loads ID #5 into memory. It does not change the specification of which ID is to be used. After entering the eight, and dropping carrier to hear the "R", the load program is waiting for further instructions. The ID is loaded in a character-by-character fashion. Dits are zero, dahs are one. The characters are loaded in the same as they are in Morse. For instance, take the letter "F". This is di-di-dah-dit, corresponding to 0,0,1,0. To enter "F", then the sequence should be 0,0,1,0. When the letter is entered, enter a 2 to signify that that letter is done. Continue loading characters in this manner. A 2 entered with no zeroes or ones will automatically be translated into a space. When the entire message has been entered, a 3 signifies that you are

equipment is General Electric MASTR. This includes the voting selector, receivers, transmitters, and control shelves. The voter has two outputs: the COS line and the audio output. The COS (carrier operated switch) is low when an incoming signal is present. This is at a transistor level, and, actually, we added single transistor inverters in several places throughout the system to interface the various components exclusive of the control system. All audio lines in the system are balanced. The control system is designed for balanced lines; therefore, it will work with both balanced and unbalanced lines. If you use unbalanced lines, be certain to keep track of the hot and cold ends so that they match up. There are select and disable lines driving the voter. These lines are active low. The control system provides a ground when commanded; otherwise, the select and disable lines are open.

The 440 control receiver has the COS and audio lines the same as the voter. Additionally, Private Line™ or Channel Guard™ subaudible tones may be required to unsquelch it. This "PL" enable line requires a ground when it is desired to place the receiver into the PL mode.

The two meter repeater is connected to its control shelf (standard MASTR equipment) in the ordinary fashion. The PTT (push-to-talk) line is just that. The PTT interfaces with the rest of the system only through the control system. It is used for two purposes: to keep the transmitter on the air during IDs and to see if the repeater has timed out. The control shelf provides the three-minute timer and drop delay timer. The PTT line is disconnected from its normal feed. During normal operation, the control system reconnects the PTT and feed. The transmitter audio pair is the audio input to the transmitter. This is shorted out to block repeating of touchtones and is shorted with the same lines from the 440 transmitter for linkups. The "PL" audio input is any audio input

Command Codes

done. The repeater acknowledges this with an "R", and the ID load and command commands are exited. Normally, place a space at the beginning and at the end to make the IDs uniform. Always be certain that the ID load mode is left, or the controller will be waiting to receive a "3" before it resumes its normal functions. After loading a message, you should select ID #5 and either wait to hear it or reset the ID timer to hear it to verify that it received what you think it did. After loading and verification, the desired ID mode can be set (either 5 or 7).

Command zero is the most powerful command, and it is through it that positive control is established. After releasing carrier and hearing the "R", the output mode is entered. In this mode, the repeater is waiting for three digit codes specifying which output bit to change. There are 64 bits arranged as eight eight-bit ports. Port 0 is a dummy port; it has no output lines and is used to disable the user functions. Port #1 is used by the indirect commands and is not normally used in the output mode. Ports #2 and #3 are enable functions. Port #4 is completely spare, port #5 is voter receiver disable, port #6 is voter receiver enable, and port #7 controls the touchtone generator. For ports #5 and #6, the bit number is the receiver number. This leaves room for eight receivers with no changes necessary. The normal configuration is all ports zero. This gives an ungrounded condition on the voter and spare ports. The three digit sequence for the output mode is XYZ, where X is the port number, Y is the bit number, and Z is either 0 (normal) or 1 (asserted). After each output sequence, the output routine acknowledges with an "R" if the command is valid. Invalid commands would be 831, 690, 300, 236, for obvious reasons. After each sequence, the output routine waits for further commands until a * is sent. The repeater sends an "R" to this and output and command modes are exited. For example, to turn off 67: enter command mode (6*#, #*6), 0, (output mode), 281 (turn it off), * (exit command).

Command # permits loading of the telephone number stored for the single digit #1. Simply send the telephone number followed by a *. An "R" acknowledges loading and exits command mode.

Always be sure that you have left the ID load, output, and load telephone number modes. If the repeater IDs, you have. This is true for all commands. A useful command to execute before ending a control session is the reset timer command, to hear the ID which guarantees that all is OK.

```
1#1 - 150/450 link
2#2 - Tape loop
3#3 - Disable blocking until carrier drop
4#4 - Touch Tone(R) Test
5#5 - Repeat 4#4 or autopatch number
67# - Autopatch

which is not affected by the normal talk audio. It is used for the CW ID tone. The CS COS (control shelf COS) will key the transmitter when grounded. This goes through the two timers in the control shelf and drives the PTT feed. The CS AUD (control shelf audio) pair goes through line amplifiers and compressors to drive the transmitter. This is normally connected to the voter audio output. The RUSOS lead is a lead which, when grounded, keeps the transmitter on through the timers. A ground on the RUSOS lead will not feed back on the CS COS lead. The RUSOS lead is grounded for autopatches. The DUPLEX AUD is a bidirectional audio path. It is labeled "AUD" on the rear of the control shelf. When the CS COS is low, audio exits from the DUPLEX AUD lead. If +10 volts is placed on the AUDIO GATE line, audio placed on the DUPLEX AUD pair will be fed to the transmitter. This is used to place telephone line audio on the air. When the DISABLE TIMER lead is grounded, the three-minute time-out timer is bypassed and the repeater will not time out. This is used during emergency telephone calls. The time-out timer is on the input, not the output of the repeater. Between each transmission, the timer resets. It is not necessary to let the repeater carrier drop. However, when the "beep" is active, a fraction of a second after the input signal disappears, the repeater will beep. The FORCE TIMER line, when grounded, makes the control shelf believe that a signal is present even if it is not. This is used so that when the "beeper" is enabled, not waiting for the beep will not reset the time-out timer.

The connections for the 440 repeater use the same definitions as the 150 repeater. There is a separate interface for that repeater which provides an autopatch on a second telephone line. That is not

Yaesu FT-227RA

The product review of the Yaesu FT-227RA in the January issue of 73 incorrectly states that a conversion kit is available through Yaesu. There is no conversion kit available.

of importance when interfacing with the control system, except that the autopatch logic includes a 1#1 output function so that when that code is sent, the LINK line is grounded. This permits linking up the repeaters from the 440 end.

The telephone line interfaces with the control system and is switched properly by it. In this system, the telephone company interface device is at a member's house. There is a dedicated line from his house to the repeater site. The audio and a reversing dc voltage are on the single pair, and its operation will be described later. If the telephone company interface device is to be located at the repeater, all of the necessary signals are present in the control system to handle it and it would be simpler than our arrangement. There is a tape recorder connected to the line during autopatches, and the recorder is located at the member's house rather than at the repeater. This allows changing tape easily.

There are various subassemblies in the control system. Rather than building everything from scratch, we used good quality commercial units where possible. There are three audio amplifiers. Two are used for the telephone line and one for driving the touchtone decoder. The amplifiers are IT&T K227s. They are balanced input/output, 600 Ohm. The gain is variable from -.5 to +36 dB, and they each draw 18 mA from a 16- to 24-volt supply. Similar amplifiers should not be too difficult to find, or a few op amps should do the trick nicely. The touchtone decoder is an IT&T K-247-B. It is normally 600 Ohms and is modified for 10k audio input impedance. The digit lockup is disabled. The decoder has 13 outputs: one for each of the 12 digits and one which detects any valid touchtone (VTT). Each of these lines is normally open and goes low when active. Any decoder may be used which follows these conventions, but beware of 567-type decoders which do not employ high/low audio group filtering. I encourage the use of commercial decoders. Lacking that, be sure to test homemade ones extensively. While the microprocessor is the brain of the system, the decoder is the heart of the system.

A standard touchtone pad is included to facilitate controlling the repeater when at the repeater site.

The tape loop is a Mohawk Message Repeater. This is an antique vacuum tube device which could certainly be replaced with a newer piece of equipment. When one pair of wires is shorted, it activates the tape. While the tape is running, an output pair is shorted. Any cartridge-type machine should be suitable, and a standard 8-track player could be modified for this use. The tape must turn itself off when completed. ■

The Cosmac Connection: Part 2

—meeting Mr. Morse

Program your way to CW happiness.

Now you can reduce operator fatigue in that next CW contest by storing commonly used messages in your microcomputer, all ready to be sent automatically at the flick of a switch. Imagine relaxing in your armchair . . . you reach over to your computer, flick a switch, and out comes CQ FD CQ FD DE VE3CWY/3 K. No answers? Flick the switch again for a repeat. You've got somebody. You casually call him with your hand key, W1XXX. Then push another button on the computer and presto! Out comes DE VE3CWY/3 QTH HR IS. . . You wait until it's finished. The code is the best you've ever heard. Now how much simpler could things get? Not much, unless you also have an automatic Morse decoder, too! Of course, you don't have to be a contest operator to use this little gem. I use it now for many regular QSOS to put out the initial CQ and to send the first message, which, for most people, is simply a signal report, QTH, and operator's name.

Equipment Required

The Cosmac microcomputer constructed around the CDP1802CD CPU is used with 256 bytes of RAM of which 105 bytes are used for the main program, the rest being used for storage of the messages. Program timing assumes a clock frequency of 1 MHz, but it is easily adapted for other clock frequencies. Other hardware that you will need is shown in Fig. 1. This includes some ICs to interface the computer and hand key to the transmitter and a sidetone oscillator.

How the Program Works

The byte stored in M(0004) is selected initially by the operator from Table 1. This byte sets the length of a dot and hence sets the speed of the code. The program triples this to get a number that will represent the length of a dash; this is stored in R6.0. Four times the dot byte represents a word space, and this byte is

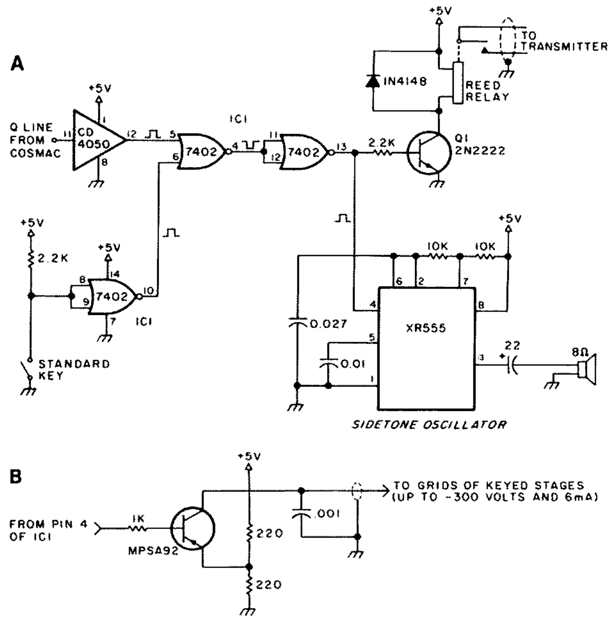

Fig. 1.(a) Interface between Cosmac and transmitter; (b) alternate circuit for rigs with grid-blocked keying eliminates relay and Q1.

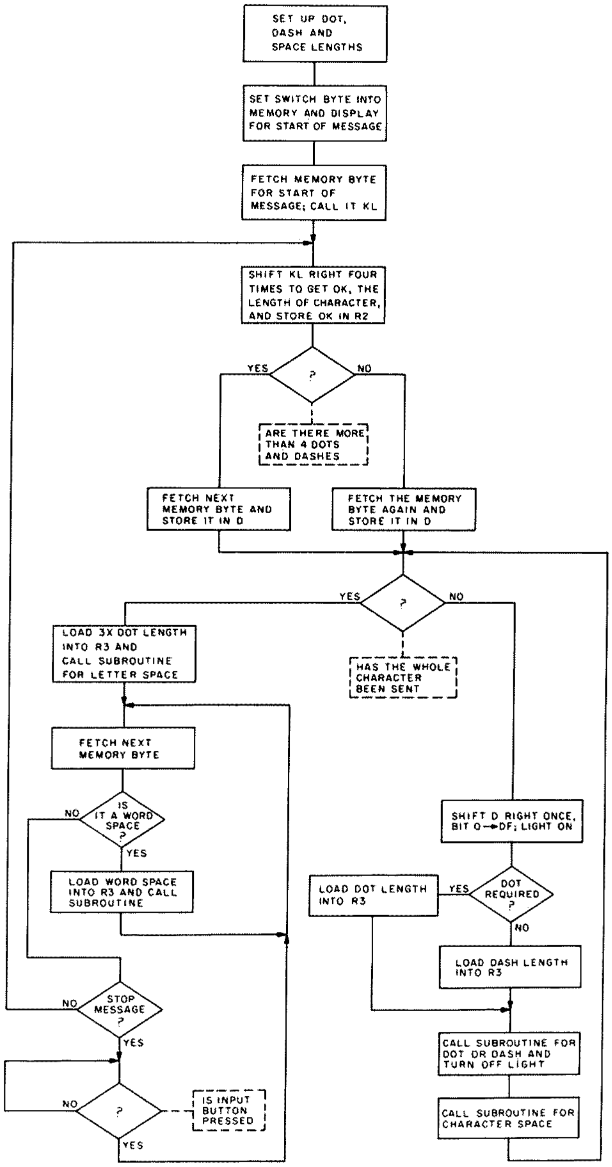
stored in R7.0. Actually, this space gets added to the usual space of three dots that follows every letter so that the actual space between words is equal to seven dots. These bytes are later used to specify the length of a timed loop and thereby set the length of all the dots, dashes, and spaces.

The program fetches the first byte of the programmed message from M(0069). It is 45, which stands for the letter C, as you can see from Table 2. The first digit, 4, is the total number of dots and dashes in the letter. The second digit, 5, specifies the order in which the dots and dashes appear. Taking C as the example, —·—· can be represented in binary form by 0101, where the 0 represents a dot and the 1 represents a dash. This is the binary code for the number 5. So byte 45 tells the computer the order of dots and dashes and the number of dots and dashes in the letter. To actually generate the code —·—·, the number 0101 is stored in the D-register. D is shifted right giving 0010, and the 1 that peels off the right end of the number tells the computer to send a dash first. D is shifted right again, giving 0001; this time, a 0 peels off the right end, producing a dot. A third shift gives 0000, pushing a 1 off the right end, thus making a dash. A fourth shift gives 0000, pushing a 0 off the right end; this makes the final dot. The computer stops shifting D now because the 4 in byte 45 tells it to make only 4 shifts. A letter space is then generated and the next byte is fetched from M(006A).

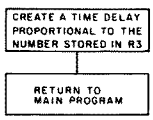
Since there are no letters that have more than 4 dots and dashes in total, the order of dots and dashes in any letter can be represented by four binary digits or one hex digit. The numbers, punctuation, and other special characters listed in Table 2 contain 5 or more dots and dashes. To handle each of these, two bytes are required; the first specifies the total number of dots and dashes, while the second specifies the order in which they occur.

The rest of the program is easy to follow from the

Fig. 2. Main program flowchart.



Subroutine flowchart



R0—forms timed loop in subroutine, setting the speed of the code
R1—main program counter
R2—stores the total number of dots and dashes in the character being sent

flowchart in Fig. 2. Two special bytes were set up. One is EE, which calls for a word space; the other is FF, which halts the program until the input button connected to EF4 is depressed.

Using the Program

Select the code speed desired from Table 1 and store this byte at M(0004). Table 1 was constructed assuming a clock frequency of 1 MHz. If your crystal is not 1 MHz, simply experiment a little with different hex bytes to get the different speeds. The code speed varies inversely with the size of byte.

After entering the main program, decide on the messages you want and select from Table 2 the bytes for each letter, number, or punctuation. Note that the numbers and punctuation require two bytes each. Terminate each message with FF so that the program will halt. To initiate one of the messages, enter the memory address of its first byte from the front panel of the computer using the toggle switches. Turn on the run switch. When the message terminates, you can make it carry on with the next stored message by pressing the input button which is connected to EF4. This way, you can have pauses inserted in messages to allow you to enter a signal report or callsign manually.

Interface Circuitry

The circuits shown in Fig. 1 are just suggestive. They work for me, but you may have to adapt them to your own rig. One possible area of difficulty I have noticed is that of rf from the transmitter getting into the IC gates and playing havoc with them. The problem seems accentuated at 14 MHz and higher with my 180-Watt rig. Typically, after a few dots and dashes are sent, the transmitter comes on and stays on. The cure is to shield the IC circuits in a metal enclosure and bypass incoming and outgoing leads with 0.001 uF ceramic capacitors. ■

Learning the Code

—a better way

Let your micro be your guide.

George Waldie
26 1/2 S. Main St.
Mt Gilead OH 43338

To get my ham license in 1949, I had to produce one minute of perfect copy at 13 wpm. A full year's striving to reach this goal resulted in a set of conditioned reflexes by which the code sounds entered my ears and came out my fingers as written text, after which the message was interpreted by my eyes. This roundabout process caused habits which have ever since inhibited both my skill and enjoyment where CW is concerned. The inclusion of my handwriting in the process was particularly unfortunate since, under pressure, my writing tends to become rather spastic. The process inhibits the ability to "copy behind" and to "copy in the head."

I needed a method of creating a new set of reactions which would generate mental images from the code sounds. Many ideas came to mind, but none provided a simple method of coordinating audio and visual presentations of characters, together with flexibility, without complicated special-purpose equipment.

Then, a couple of months ago, we added an audio alarm to our office minicomputer. This alarm gives a single 960 Hz beep in response to PRINT HEX(07). It is used to signal the operator when the machine needs attention for any reason foreseen in the program. Once I found that the duration of the tone could be controlled by changing the number of iterations in a loop containing this statement, it was inevitable that I would program a code teaching machine.

I have written this article hoping that others with similar CW problems, or those conducting code classes, will find the system useful and will let me know how they fare. The program contains a few wrinkles which may prove interesting to persons concerned primarily with programming methods.

Practice material can be stored in data statements in the program or, with simple changes, in external files. The program accommodates a full range of numerals, punctuation, and upper and lower case alphabetic character material. As the text is scanned, each character is converted into its audible CW equivalent and, an instant later, appears on the CRT as an addition to the string of previously sent characters.

The code element speed and the element and character spacings are adjustable, as well as the delay of the CRT display of the character. There are a number of apparent advantages to this system. A student working solo with this program need never try to memorize the code from any printed representation, either in dots, dashes, or didahs. All that is stored in the program. The code sound is emitted, and then the letter appears on the screen to reinforce the character recognition. For code classes, practice material can be selected from any source and stored for later use. The instructor can input text to his machine and then recall it as CW at any speed appropriate to class needs. My equipment will store 80,000 characters on a cassette, some 16,000 words, or 64 typed pages of text. Such material can be used over and over at any desired speed.

Characters are handled in a computer as binary numbers which have decimal, octal, and hexadecimal equivalents. In developing this program, it was necessary only to consider the ASCII decimal equivalents of the various CW characters. Fortunately, and possibly not coincidentally, the characters used in CW transmissions

are represented by ASCII decimal numbers lying in the range 40 to 90. A table of these characters is shown in Fig. 1, together with the string symbols used to control the audio output. Lowercase letters are represented by ASCII decimals 97 to 122. A few characters — the star, semicolon, "less than" and "greater than" symbols, and the @ sign — have no international Morse symbols that I could find, so provision is made to skip these characters when encountered.

The equipment required to use this program is a small computer programmable in BASIC with STRING functions, a CRT display, and an audible tone alarm. The version of the program given here, which includes several lines of practice text, runs in about 2350 bytes.

My machine is a Wang WCS1OT, which includes the CRT, cassette drive, and keyboard in a single console with an outboard CPU. The BASIC compiler is hard-wired, so I do not have access to the machine language. Wang BASIC is an augmented subset of general BASIC, and only those features special to STRING manipulation and character identification have been used. If your BASIC lacks any of these features, but you can write machine language functions, you should be able to run a version of this program. Notes relating to conversion of the program to other dialects are located at the end of the article.

The program can be followed readily from the listing of Fig. 2. A word is in order about this listing. The program was originally written and debugged using one statement per line. When operation was satisfactory, the program was "compressed" by removing REMs and combining as

Fig. 1. ASCII decimal codes, characters, and CW sound codes.

many statements as possible on each line. This saves a sensible amount of core and results in an almost unreadable LIST. To get the listing given here, the compressed program was processed by a utility which prints one statement per line and indents FOR/NEXT loops. The line numbers went unchanged throughout, except for deletions, accounting for the peculiar sequence shown here.

Now for program operating: At LN 30, the variables are dimensioned as necessary. C$(52)8 provides for a list of 52 code symbols, each 8 characters or less.

M$64 sets up a string variable containing up to 64 characters to receive text lines.

T(4) is a list of the speed control numbers.

T$(4) is a string list to receive speed prompts. In this BASIC string, variables with no specified length take a default of 16 characters. So the prompts can be up to 16 characters in length.

A$1 sets up a single character variable.

At LN 80, a loop READs the speed data prompts from DATA into list T$(). Then another loop READs the code symbol strings into 52-element list C$(). At LN 170, a third loop displays each of the prompts on the screen. An "edit" routine follows, providing for inputing the necessary control numbers. This method of data INPUT is one I use rather routinely, but it is not essential to the program. The Wang INPUT statement allows the inclusion of the prompt message in the statement. If you lack this feature, you should use a PRINT statement "CHANGE ITEM #" preceding INPUT. Each INPUT of a value causes a loop back to LN 170 where PRINT HEX(03) blanks the screen and prints a new data display from the top. When the necessary controls have been entered, "0" used as an answer to "CHANGE ITEM?" will exit the edit routine.

The change of variables at LN320 may seem unnecessary. My computer has a HALT/STEP key which will interrupt program operation at any time and permit the program to

be restarted after changing the value of a variable. Use of the unsubscripted variables makes the value changing a mite simpler during an interrupted RUN.

The next statements blank the screen, set the DATA pointer to the beginning of the practice text, and move the cursor to the center of the screen, respectively. HEX(OA) is a line feed.

At LN 410, the next text line is READ and tested. If the DATA is not "***", the program continues, otherwise the DATA system is reset and the program repeats from LN 410. If your BASIC does not have the ability to RESTORE to a particular DATA item, you will have to program an alternative at this point. This version of the program assumes the practice text is stored in DATA statements. Changes at this READ routine will permit the text to be taken from some other storage medium.

LN 490 counts the characters in text line M$, and the program enters a loop to process the line one character at a time. The next character is stored in A$, and the ASCII decimal value of A$ is put in A.

The following IF statements provide a means for accepting a variable only if it has a value between certain limits. Letting U, L be the upper and lower limits, respectively, the comparison statement is set up as:

ABS(A − (U + L)/2).LE.(U − L)/

and will reject any value outside the limits.

The first comparison rejects A unless it has a value between 40 and 90, which includes characters from "(" to "Z". Any value outside this range is tested again at LN 490. Values from 97 to 122 represent lowercase letters and are shifted to uppercase at LN 640. Any other value of A results in a blank being printed on the screen, and no code sound is generated. If your machine does not have lowercase, you can simplify the program by removing the second test of A.

A anomaly of the program as written is that a lowercase letter is interpreted so as to produce the same code sound as an uppercase, but the lowercase character is added to the screen. Of course, this presents no difficulty.

At LN 660, A is shifted in value to serve as the subscript for array C$(), and the coding for the corresponding CW sounds is stored in C$.

There follows the loop to process the code symbols. There are other ways of analyzing the symbol

```

strings, but the method shown suits my equipment and is efficient. The next character in the symbol string is CONVERTed to a numeric which then controls the branching. Any value of C but 0 or 1 generates a blank.

In the DATA statements for the character codes, you will notice the appearance of "2"s in several places. In most cases, these mark characters for which no CW code combinations were found. However, the CW period does include internal spaces which require this "2".

The "normal" branches to LN 790 and 840 go, respectively, to generators for dits and dahs. These are identical loops, except that the dah loop has twelve times as many iterations as the dit loop. If you are puzzled because you understand that a dah should be only three times as long as a dit, remember that the speed of the CPU enters here. In fact, you may have to adjust these loops to make the output sound right. The twelve multiplier was arrived at experimentally.

Both the dit and dah loops exit to 880, the intracharacter space loop. This is simply a "do nothing" loop to use up time. Again, you can change the multiplier to suit your taste (ear?). Notice that both dit and dah loops are controlled by T1, and the intracharacter loop by T2. At 940, B$ is a shift register to maintain, on the screen, the last 16 characters sent. In Wang BASIC, string variables are 16 characters long unless otherwise dimensioned. You must use whatever string length specification is required by your language. LN 940 moves the last 15 characters of B$ to the first 15 positions, leaving a space at the tail of the string for the next character, which is added in the next statement.

Another loop delays the display of the shift register. In this case, a meaningless arithmetic operation is included to provide the delay with fewer loop iterations. In the initial learning stages, this delay can allow "capture" time for CW character recognition. The delay can be reduced as the recognition time decreases.

Remember that, when a FOR/NEXT loop is encountered, it is exercised once even though zero iterations are called for. So, in this case, there will be a delay of the screen display equal to one iteration of the loop even if T4 is zero. This is the reason for the inclusion of the arithmetic operation within the loop. This seems to work well at CW speeds up to about 20 wpm, but this loop is a factor limiting maximum speed, since it does work once for every character. This is a point to look at when you try for maximum possible code speed.

After the shift register B$ is printed, there is a space

```
          IF I<>1THEN 880
          A$ = " "
          GOTO 880
790       FOR T = 1TO T1
          PRINT HEX(07);                                       Generate dit
          NEXT T
        GOTO 880
840     FOR T = 1TO 12*T1
          PRINT HEX(07);                                       Generate dah
          NEXT T
880     FOR T = 1TO 9*T2
          T = T                                                Intraelement space
          NEXT T
        NEXT I
940     STR(B$,1,15) = STR(B$,2,15)
        STR(B$,16,1) = A$                                      Register shift
        FOR T = 1TO 4
          T = SQR(T*T)                                         Print delay
          NEXT T
        PRINT HEX(0C);TAB(20);STR(B$,1)                        Print register
        FOR T = 1TO 4*T3
          T = T                                                Space

```

between characters generated by the delay loop controlled by T3, after which the program goes back for the next text character and repeats the process just described until the entire text string has been used. It then proceeds to the next string of text data.

There is another possible anomaly you should be aware of. Some BASICs include trailing spaces in text strings; others do not. If your version of the language crops trailing spaces from the strings, as mine does, you will have to add a leading blank to each text line, or the last word of each string will run into the first word of the next string without a separating space. Notice the space I have included after the leading quote in each line of the DATA statements at LN 1290 to 1330.

This program illustrates very nicely how a general-purpose computer can serve a very specialized purpose merely by software implementation.

Conversion Notes

The manual for Ohio Scientific, Inc., 6502 8K BASIC states that this dialect will run, without change, programs written for ALTAIR, IMSAI, and SWTP machines and, with slight changes, programs for PDP-8, PDP-11, and NOVA BASICS. The following notes have been prepared using this information. I regret that I have not been able to test the effects of these suggestions.

LN 30 — In Wang BASIC, the DIM statement is used to set the sizes of lists and arrays and also the number of bytes reserved for string variables. Thus C$ is defined as a list of 52 elements of 8 or less characters. There is a default length of 16 characters. This specification appears to be unique to the Wang system.

LN 170 — When the system is turned on, output is selected to the CRT. Alternate outputs can be selected, but are not pertinent to this program.

LN 170 and LN 320 — PRINT HEX(03) clears the screen and homes the cursor to the upper left corner of the screen — corresponds to TTY keyboard CTRL C.

LN 790 and LN 840 — PRINT HEX(07) keys the audio tone — corresponds to TTY keyboard CTRL G.

LN 940—Each 0A in PRINT HEX(0A) issues a line feed — corresponds to TTY keyboard CTRL J. PRINT HEX (0C) moves the cursor up one line.

LN 320 and LN 410 — RESTORE 57 resets the DATA pointer to the 57th item of data, beginning of sample text. OSI BASIC does not offer this feature. Some other BASICs allow RESTORE to a particular DATA line number.

LN 410, LN 490, LN 660 and LN 940 — STR(M$,1,3) refers to string M$, starting with the 1st character, and including 3 characters, to create a substring of M$. OSI uses MID$(M$,1,3) with same meaning.

LN 490 and LN 660 — LEN(M$) returns the number of characters in M$. OSI uses same function.

LN 490 — VAL(A$) returns ASCII decimal value of 1st character of A$. OSI uses ASC(A$).

LN 660—CONVERT STR(C$,I1) to C sets to the numeric value of numeral(s) in string variable—corresponds to OSI CHR(MID(C$,I,1).

The relation operator .LE. is not accepted by my equipment, but is used here because my output writer does not have the usual left arrowhead on its type ball. The operator stands for "less than or equal to."■

Programming a Microcomputer —6502, Caxton C. Foster, Addison-Wesley Publishing Co., Reading MA 01867, 230 pages, 6" x 9" softcover, $9.95.

The Little Book of BASIC Style, John M. Nevison, Addison-Wesley Publishing Co., Reading MA 01867, 150 pages, 6" x 9" softcover, $5.95.

Although the instruction contained in *Programming a Microcomputer —6502* pertains in a general way to any 6502 machine, it is based specifically on the KIM-1. In fact, for best utilization of this book, a KIM-1 should sit at the reader's fingertips. This would also make an excellent classroom text as long as one or more KIMs were available to the students.

An advertising flyer states that this book is also usable with the PET, but since the PET is hard to program in assembly language as yet, this hinges on Commodore providing more information about how to operate the PET.

One unusual aspect of the book is a complete lack of mention of the 6502 except in the title and in the appendix, which lists op codes and addressing modes. All 6502 attributes are indicated as if they were KIM-1's exclusive features. To quote, ". . . the inventors of the KIM-1 provided a form of addressing that circumvents the problem. It is called 'immediate addressing.'" The inventors of the KIM-1 and the MCS6502 are indeed one and the same, but emphasis should be placed on the fact that we are really talking about the KIM-1.

As the result of a coincidence, I became the happy owner of a KIM two days before I received these books. I am an 8080-Z-80 programmer and the 6502 instruction set was a foreign language to me. From that point of view, I'm a beginner, I guess.

Chapter one is a discussion of how the instruction set is used and chapter two takes you step by step through the operation of the KIM-1. Both are well done, but the true neophyte would do well to go very slowly in chapter one. At one point in chapter two, the author failed to tell the student (me!) to restore the program counter after a STOP and before a GO, which means that the following steps didn't work.

Chapters three to thirteen comprise a group of experiments. A problem is presented and instruction on methods is given. The student then writes a program to gain the desired results and attempts to run it. The author's reasoning and solution to each problem are covered in an appendix. Extensive debugging help is also given.

The experiments included involve a Morse-code oscillator, a piano keyboard, a combination lock, a tune player, a digital clock, and many more. In each case, whatever hardware is needed (very little) is fully explained. The chapters that I found most interesting concerned an interpreter and an assembler for a "Dream Machine." The "Dream Machine" is a pseudo-sixteen-bit processor whose instruction set is interpreted by a KIM program. While the instruction set is limited by the amount of KIM memory available, it is an informative and effective means of examining the operation of any instruction on any processor.

The appendices contain sections on binary math, KIM routines, 6502 op codes and addressing modes, and solutions to the programming problems contained in the text. These solutions are written

in assembly language and the student will have to reduce them to machine code in order to run them.

I would hesitate to recommend this book to the complete novice unless he has access to a KIM-1. However, by combining the information contained in the three manuals that come with the KIM-1 with *Programming a Microcomputer—6502*, I feel that I have become an effective 6502 programmer.

The Little Book of BASIC Style wasn't what I thought it would be. Rather than attempting to teach you how to program in BASIC, it is concerned with writing programs so that they can be more easily read by the user.

Nevison contends that programs that are readable are better programs and that they will run the first time with fewer problems. Twenty rules are presented and woven into a discussion which advocates clear structured programs. Many of these rules make good sense, but some are difficult to put into practice.

Variable spacing within a line to make it easier to read won't work if your BASIC interpreter (like mine) eliminates all excess spaces. Using a blank line to separate blocks of code is also a good idea, but it is another no-no for my BASIC.

The author calls for more comments within the body of a program to make for better understanding. One of his programs contains more lines devoted to remarks than it does operational statements. If you are like most computer hobbyists, you don't have the excess memory that all of those remarks take. I like well-commented programs, but I usually strip off the remarks at entry time. But that doesn't mean that you shouldn't use remarks while writing programs. They will clarify to you and anyone else who uses them what is intended.

Each of the rules is presented with one or more examples. Both good and bad methods are shown side by side so that it is easy to see the advantages of style. Many of the rules, such as matching the variable to its meaning—V = Value, I = interest, etc.—and labeling constants, make very good sense. Have you ever attempted to read a poorly-commented program and tried to figure out what purpose each variable and constant served?

After a discussion of the rules of style, some practical examples are given: sorting, craps, plotting, bar graphs, dealing a deck of cards, and more. And then comes the biggest program of all—STYLIST. STYLIST is designed to style your programs for you. While it is a huge program meant to do a task that the programmer should be doing for himself, it does present itself as an example of how to structure a program correctly.

After studying *The Little Book of BASIC Style*, take one of the better programs that you have written and rewrite it according to Nevison's twenty rules. You'll be surprised at how much more readable it is, and six months from now, you'll still be able to figure out how it works without having to rewrite it again.

Addison-Wesley publishes many other computer titles and their 100-page *Business and Computer Science Catalog* should be in every computerist's library. I have just read an advance flyer on the third volume in *The Joy of Computing* series, *BASIC and the Personal Computer*, and I am looking forward to its publication. ■

The 2 Meter ECM Caper

—James Bond, move over!

Snake-Oil gets shut down.

Byron H. Kretzman W2JTP
431 Woodbury Road
Huntington NY 11743

The "Conditional," or Class C, license began many years ago when regular licenses were Class A and Class B. Honest in original intent, the Class C license was supposed to encourage ham radio for the handicapped and others who lived more than 75 miles from an examination point and couldn't make the expensive and time-consuming trip to an FCC office. Later, the distance limit became 175 miles. General Class privileges were available to the Conditional Class, which replaced the old Class C. All that was needed was for someone to swear that 13 wpm could be copied and, as for the Technician Class, to "supervise" the mail-order technical exam.

Because the change from 75 to 175 miles was made not too many years ago, a fair number of phony Conditionals exist, many of whom "bought" their licenses for cash or favors from some radio amateur without ethics. Phony Technicians exist, too, but we won't go into that since this is the story of what happened to a certain phony Conditional. Two meter FM seems to attract these people, for some reason which escapes me.

The story is fascinating. I wouldn't believe it if it were told to me. I'll change a few names to protect the guilty. Even so, I'll bet a dime it reminds you of somebody on FM you know.

It all started when my old friend John came over one night to chew the rag about the DX he works and the DX I used to work. John is an electronics engineer at the local electronic countermeasures (ECM) factory, but he gets his kicks out of working DX on CW. Like me, he uses 146.94 to keep in touch with his local ham friends. We were discussing VR6AY on Pitcairn Island when the .94 receiver opened up to interrupt us. There was Snake-Oil, sounding off like an expert to his phony Technician friends. John says, "Let's have some fun," taking my code practice oscillator off the shelf and standing it in front of the microphone. As soon as Snake-Oil stands by, John gives him a one-by-one call on the straight key at a brisk 10 wpm. Snake-Oil comes back, not to John, but to one of his friends, saying "Hey, the band is

really open tonight! Just heard the code ID of the repeater upstate!" John looked at me, reached for my *Callbook* and quickly thumbed through it. Finding Snake-Oil's call, he says, "Just as I thought!" and points to the "C". To prove the point, John broke in again with the CPO, sending only Snake-Oil's call, but three times, at about 5 wpm. No answer. Snake-Oil couldn't even recognize his own call!

As time went on, Snake-Oil more and more incurred the wrath of John and other old-timers by setting up a .34/.94 repeater, but his popularity as the local FM "expert" grew as the number of appliance operators grew. Within about six months, .94 became almost useless for a simplex channel. I told John it was impossible to fight this, but he answered, "Don't you ever watch 'Mission Impossible' on TV?" I thought he was kidding.

As I worked around the shack now, .94 never seemed to shut up. It was alive with talk about the coming Division convention. Snake-Oil was on the program and would demonstrate his FM repeater with its vast satellite receiver system which enabled anyone with a hand-held rice box to use the repeater from anywhere in the county. (Snake-Oil was a really busy fellow.) As I said, there wasn't much simplex activity on .94 anymore, and the old-timer didn't like standing in line to use the repeater while all those rice-box mobiles were telling each other what exit they just passed on the expressway. The local intercom feature of .94 seemed to be giving way to "progress."

One Sunday morning, while driving down a street near Snake-Oil's house, I noticed a cable-TV truck parked by a telephone pole about a block away. I caught a quick glimpse of a guy in coveralls and a hard hat. There was something familiar about the guy, but I couldn't put my finger on it. On the way home that afternoon, I saw the cable-TV truck in another part of town. This time I took a real close look at the guy in coveralls. The bell rang—it was John, but with a mustache??? The next Sunday I saw him again in another part of town. What the hell was going on? John is a well-paid engineer. He wouldn't be moonlighting as a pole jockey for a cable-TV outfit, would he? And, how come on Sunday? Was this a gag?

The more I thought about it, the more curious I got. Finally, I couldn't stand it any longer. I called up John, who had been "too busy" lately to come over to chew the rag about DX, and insisted upon going over to see him that night. John was in his basement, at his workbench, apparently breadboarding a bunch of transistors and ICs. This struck me as strange, too. John wouldn't be doing any homework for his job, as his work was highly classified, and John's ham interest was operating—working DX.

I let him have it with both barrels. We were old enough friends, I told him. He could darn well let me know what was going on, as I had a strong feeling that it had something to do with ham radio.

John swore me to secrecy, and then proceeded to unfold the wildest, most complex scheme imaginable, a scheme designed to completely foul up Snake-Oil's coming Division convention demonstration of his repeater system. Pulling out a drawer of his workbench, John showed me a small collection of plastic pill bottles, each with a very short, stiff wire coming out the top and a longer, flexible wire coming out the bottom. Then John took down from a shelf above his workbench a small black box, also with a short stiff wire on its top. The box had several push-button switches, one of which was labeled, "destruct." This switch had a safety cover which had to be flipped up and held up before the switch could be actuated.

As John explained it, each pillbox was a transponder which would generate white noise, upon command, across the entire 2 meter band. John demonstrated it on his .94 receiver. The noise compensated squelch of the FM receiver would simply cut off the audio in the presence of the white noise, which also covered any signal. Of course, the small size of the transponder made its range very short—hence John's crazy scheme of planting one on top of a convenient telephone pole (so it wouldn't be noticed from the ground) close to each one of Snake-Oil's satellite receivers. This he did by borrowing the cable-TV truck from another friend and using it on Sundays to climb the poles himself. The truck was as common a sight in this county as a telephone company truck.

"What's with the 'destruct' switch?" I asked John, having the distinct feeling that this was no gag either. Obviously, John was utilizing considerable know-how from his job at the ECM factory.

"Well," John replied, "with all these transponders out, sooner or later one would be discovered, and it wouldn't take the FBI long to trace it to me."

At this point, John took one of the miniature transponders and set it up on top of a stick stuck into the ground in the middle of his backyard. "Watch!" John manipulated the buttons on his black box and the transponder went "pooff!" A bright flash, a small wisp of white smoke, and the transponder was gone! John said, "Don't worry, I've got plenty more of them!"

"What happened?" I asked.

"Thermite," John answered. "A small amount, in the bottom of each pill bottle."

I went home shaking my head. This whole crazy scheme (were all ECM engineers this crazy?) seemed to be an awful lot of trouble just to foul up Snake-Oil. I could think of lots of ways to foul him up, more simple ways, but they all involved long jail sentences for the violence required.

Two days before the convention, John called me up and told me that all was ready. All the transponders were planted, one near every one of Snake-Oil's satellite receivers, all over the county. The black box was mounted in John's car, ready for the operation and then the "destruct" trips around the county.

The night before the convention, John called me up excitedly. "Guess what?" he asked, immediately answering the question himself. "Snake-Oil got called in by the FCC for reexamination, and he flunked not only the 13 wpm test, but the 5 wpm test as well, so they lifted his license!"

What a let-down! All I could think of was the tremendous wasted effort John had put into this crazy jamming project. That night, on the ten o'clock news, it was reported that police switchboards all over the county had earlier lit up with a rash of phone calls, each reporting a mysterious flash of light in the sky. ■

"I Love My Ten-Tec!"

—a look at the 540/544

It's tough to argue with pulpit praise.

Rev. James R. Belt WA0JIH
1006 N. 76
Omaha NE 68114

For the past six and a half years, my hamming had become less and less enthusiastic. My reliable Swan 350 wasn't at fault. The level of activity on my favorite bands had increased, not diminished; that wasn't it either. There is just no way to know why our interests rise and fall. But then, something did happen. One morning, on one of my few remaining skeds, a good friend commented on the fact that tubes were becoming scarce. RCA had gone out of manufacturing tubes and others were soon to follow. What would replace them? Transistors, of course.

That did it. My mind went into a "red alert" condition, and I began reading and rereading all the ads and specs of solid-state rigs. True enough, there were more and more solid-state transceivers for the HF bands. Heathkit's SB-104A and the Atlas 180 had given way to the 350XL, and the little 210X and 215X seven-pound delights were right there in the Atlas lineup. A strange new company had come out of nowhere, and they were producing something called a Triton IV (now termed the 540 or 544) which sounded good. Ten-Tec was its name. A quick overview of the situation reminded me of what I had forgotten. These were the people that came out with the little modules and finally the QRP rig, the Argonaut with 5 Watts input. That did it. Over to the local radio emporium I went. What a display. There they were—the Kenwood TS-520S and the TS-820S, the Yaesu models, the Atlas, the ever-changeless Drake line, and the Ten-Tec 540. One by one, I listened to them all, but one was a standout: the Ten-Tec 540. Words fail me. It was like listening to pocket radios before walking into a high fidelity store for a demo. The receiver on the 540 was fantastic!

But, when I listened around the band, all I heard were TS-520s. What could I do? I took the plunge and bought a Ten-Tec 540, the CW filter, and the ac power supply. My ham life hasn't been the same since. My ham activity has skyrocketed.

It's been about 16 months since I first put the 540 on the air. The first thing I noticed was the absence of warm-up. Press the button and the machine speaks. The single-conversion receiver has a bandwidth of 2.7 kHz, which gives none of the squeezed audio that is often apparent with narrow designs. One overlooked factor comes in the audio distortion spec. Every receiver on the market has a 10% distortion allowance, but not the 540. It has 2%, or 1/5, the amount of unpleasant noise to listen to along with the signal. That makes a big difference when you are on the air for over an hour or so. The 540 has a little 2" speaker located in the center of the bottom of the unit that outperforms two separate outboard speakers that I've tried so far. The receiver and the transmitter are not tied together as they are in most of the transceivers on the market. Peaking up or detuning the receiver doesn't affect the transmitter at all. Using the remote vfo doesn't automatically mean that the further you go from the transmit frequency, the more your receiver is off resonance! That's quite a remarkable feature of broadband design, especially if you are a DXer. Stable? You bet. 10 Hz allowed by the specs per hour hardly makes it worth mentioning. The sensitivity is really closer to .2 μV instead of the .3 that is advertised.

The standard for most units is .5 μV. The receiver is quiet. The absence of the ac supply from the unit and the lack of tubes all make a contribution here.

The transmitter does as well as the Swan 350 with its 400 Watts input. The Ten-Tec 540/544 has 200 Watts input on all bands and all modes including CW and RTTY. Output is about 100 to 110 Watts. I have had many, many QSOs on crowded bands that have lasted 45 minutes to an hour with the Ten-Tec. The reports all indicate good audio and a lot of punch to the SSB signal.

It really does get out smoothly and superbly. I did buy a DenTron Super-Tuner to match the 540 to my old inverted-vee dipole. The swr bridge is built right into the 540/544 so that, in the transmit mode, you can monitor swr without an external meter. I just reach over and touch up the knobs on the tuner while I'm transmitting if I change frequency very much. This past year, I worked Sweepstakes for the first time. What fun! I'd just go from one end of 40 meters to the other, hitting all the strong signals instead of sitting in one place with a kilowatt. The sprightly rig and that broadbanded design made it work. Many folks don't like contests and don't move around the band that much, but I do and it's nice to have the capability.

The features of the Ten-Tec are well chosen, making it the most versatile rig I've ever come across. Take the 25-kHz calibrator. It's pulsed so you can distinguish it from a carrier. WWV is obtainable on both 10 and 15 MHz. It's the only rig I know of that has that capability on two frequencies. For the CW man, there is a $25 filter for 150 Hz—that's right, a two-position filter. I tried another well-known outboard CW filter, and it didn't surpass this little wonder. The full break-in keying for CW is like having your sinus cavities open . . . wide! One fellow 540 owner told me that he thought his transmitter wasn't working until the station came back to him. You can listen to the band in between the dits on the number 5. There's more for the CW addict. The sidetone not only has adjustable volume, but there is also an adjustment for the tone over a full octave to beat off the wearies of listening to the same tone. Both adjustments are made through a hole in the bottom of the unit that doesn't require moving the unit.

If you work round tables, you know how vexing it is to wander around from one station to another, so the Ten-Tec people have incorporated an offset tuning control on the front panel . . . with a little LED to let you know when it's working. It has an effective noise blanker for any kind of impulse noise for an additional $29.

The back of the radio has all kinds of switches and plug-in possibilities. All of the plugs are available for phone patches, linear amplifiers, external receivers, external speakers, foot switches to activate the mike, and a plug to take the remote vfo or 160 meter converter.

The alc is adjustable on the front panel so you can reduce the power input to 75 Watts if you are on emergency power. The 540/544 is essentially a 12-pound dc-powered unit drawing 15 Amps on peaks, so it can function well on a 12-volt battery stuck in a corner of the shack for emergencies. Naturally, that 12 lbs. goes a long way toward making it an ideal mobile station. The dimensions are a bit larger than the Atlas 210X, but not nearly as great as many of the hybrid (tube-transistor) rigs on the market.

What about protection? Well, the radio is designed to shut down if you forget to put the antenna on or if the swr is too high. It doesn't blow a fuse; it just quits playing. That has gone a long way toward keeping the transistors in the final from requiring replacement. The factory said that they have only replaced 6 transistors so far in the thousands of units on the air around the world.

The service of the Ten-Tec people is outstanding. I started off with a used Triton IV, and, soon after I purchased it, the antenna relay stuck and I had to key the mike to get it to go back into receive. It wasn't a big problem, but it was annoying. I called the factory, and they shipped me a little circuit board via UPS that took 3 days to arrive. I sent the old one back. Even though the unit was way out of warranty, they made that swap at no expense to me. There are ten circuit boards in the unit that are all field replaceable. The rig is sure easy to service. There are no high voltages to induce a healthy fear in the amateur. The layout is clean, neat, and simple to get at. The manual is a joy to read. Every circuit board is clearly described and defined.

The Ten-Tec 540/544 is one of the finest, most versatile HF rigs I've ever seen and easily the best radio that has ever graced my ham shack. Over the months that I've been on the air with it, I've listened to many other amateurs operating this particular piece of equipment. They have experienced the same service that I've experienced from the factory, and they are uniformly delighted with their good fortune.■

A $5 Phone Patch

—the darn thing really works

If you think you've seen everything in phone patches, check out this one's price tag.

Lewis Tarnopol WA6RJK
164 South Kingsley Drive
Los Angeles CA 90004

After reading Mr. Johnson's home brew phone patch article (D.H. Johnson, "Phone Patch Tips," *73 Magazine*, July, 1977, p. 138), I thought I might throw my hat in the ring, too. I built this phone patch into an old desk model extension phone several months back and it has worked great from day one. In building it, I discovered some very useful hints I'd like to pass along.

Before building or buying a phone patch, I had a few basic criteria to meet. First it had to be cheap! Also, I didn't want VOX—it costs more and its features appealed to me less. With VOX, the beginnings of sentences sometimes tend to be clipped off. Being picky, I preferred the more natural sounding voice. Since I had to monitor the QSO and add 10-minute IDs anyway, I opted for manual control of transmission and receive. Installation of a small SPST switch to control my Drake T-4XC push-to-talk (transmit relay) circuit would allow the person on the phone to talk without receiver noise being present. Any transceiver or transmitter/receiver combo should be able to accept this simple switch, allowing hassle-free communication.

Once the decision had been made, I went to work drawing on paper what I needed and then scrounging in my junk box for the parts. Being a recording engineer, I found one small low-to-high impedance transformer, some audio cable, and all the plugs and jacks (audio-type) I needed. A quick trip to the neighborhood electronics shop took care of the rest.

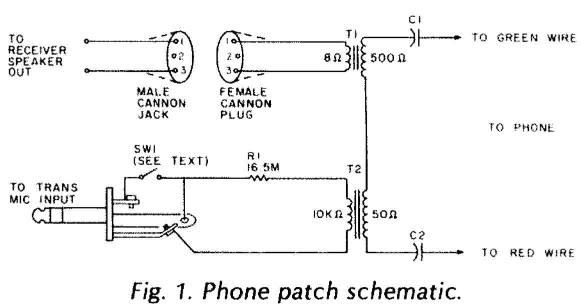

Fig. 1. Phone patch schematic.

Construction

The phone patch schematic is shown in Fig. 1. The phone line impedance is about 600 Ohms. It makes sense to match that impedance as closely as you can because doing so will yield excellent fidelity from the phone mouthpiece. Since I had one transformer with a low impedance side of 50 Ohms, I connected, in series with it, another transformer with a 500-Ohm side. Figuring 550 Ohms to be close enough, I let it go at that. Then I connected up one capacitor in series with each "hot leg" of the phone. This gave me isolation from any dc. I found that 3 uF was a good choice for fidelity reasons. This side of the circuit was then permanently connected to the phone inside the phone cover. I'd like to add that there have been no problems with this permanent arrangement and one could easily put in a switch to disconnect it if desired.

The other side of each transformer was hooked up to its respective device. The high-impedance (10k) leads went to the mic input of the transmitter and the low-impedance (8-Ohm) side went to the speaker output of the receiver. For the speaker, I ran speaker cable connected in parallel to the speaker output of the receiver, soldered on a male Cannon connector, mounted it in a small metal box I had handy, and attached it to the front of my ham desk. It's very accessible. I then soldered a female Cannon plug with about 3 feet of wire to the 8-Ohm side of the transformer. Thus, whenever I want the receiver audio in my phone, I simply plug the Cannons together. I made a plug which, when inserted in the mic jack of my Drake, connects together both the audio wires from the transformer and the two wires leading from my trans/receive (PTT) switch mounted in the phone cover. (For Drake, PTT amounts to shorting out ground and ring on the plug for transmit. I presume most ham PTT functions can be switched in and out similarly.) Cable for the mic section of the phone was good shielded cable. Its use prevented any possible hum from entering during transmission. I recommend always using shielded cable for high-impedance applications in audio.

Originally, the 16.5-megohm resistor (made from a 10-megohm and a 6.5-megohm in series) wasn't part of my plan. Without it, however, I cleverly discovered the phone mouthpiece would *clip* the input of the transmitter. Turning down the transmit gain didn't stop the distortion. Instead, I made the phone yield the same output voltage characteristics as my Shure 444. By inserting the resistor, I had *no* distortion and excellent voice quality. Hooray for carbon mics!

Results

The very first day I assembled my phone patch I had the opportunity to use it. There was a ham in Iowa who wanted to patch into Glendale, California. I answered his CQ Glendale, and he explained he wanted to talk to a sick friend who had almost died from illness a week earlier. I made the patch without hesitation. When the call was done, I received many compliments from both sides, thanking me for helping out. I felt extremely good to have participated in what was a very happy occasion for all.

I later made some on-the-air tests for voice quality. Nothing but compliments came from all those who heard me testing. Many times people couldn't tell the difference between my phone and my Shure! Having the ability to hook up my receiver to my phone (without the transmitter) is nice, too. When I hear something interesting, I call up a friend, plug my phone into my receiver, and we both listen. I might add that I find the transmit switch arrangement very convenient. All communications are done with the phone handset. Since my transmit switch is mounted on the phone, my left hand holds the handset, and my right hand switches the trans/receive switch. Those of you inclined to mount the switch in the handset could pull off one-handed operation. Or, how about a footswitch?

The only change I've made was to add an on/off switch for my receiver. Now I can adjust the receiver gain in the phone to any level without the distraction of an outside speaker blaring away. Since then, I've been quite happy with my home brew phone patch. All in all, I spent less than five dollars. That's what I call cheap! ■

Underside view of phone with patch inside. The wire coming out of the uppermost part plugs into the Drake's mic input. The lower wire plugs into the Cannon box below the electrical outlet (bottom of picture). The PTT switch is centered in the bottom of the front of the phone.

The Filcher Foiler Revisited

—vehicular protection

The best news for hot rods since the green light.

After reading Mr. Helvey's article ("Filcher Foiler Car Alarm," *73 Magazine*, Dec., 1977), I decided that it was just what I needed to protect my old Ford hot rod with its chrome-plated engine, dual quads, custom gauges, etc. Being a middle-aged hot-rodder in a neighborhood full of fifteen-year-olds will almost always ensure a good-sized audience for my car projects. This day was no exception.

The first thing I did was purchase all the required parts, including the door switches. Upon completion of one door jamb, I overheard a supportive ten-year-old telling his older brother in no uncertain terms that, no, Mr. Davis wasn't crazy, and, yes, it was undoubtedly going to be faster with dual light switches! After pretending (?) to go berserk and chasing all the youngsters away, I went inside to reread the article and see just why I was installing another set of door switches.

The very first thing I discovered, which was incidental to my quest, was that the relay as shown is not in a true latching-type configuration. The next thing I discovered is that most vans don't have door switches for the courtesy lights already installed. Hence Mr. Helvey's installation. Well, the Bondo job on the doorpost wasn't too difficult and neither is the new alarm system outlined here.

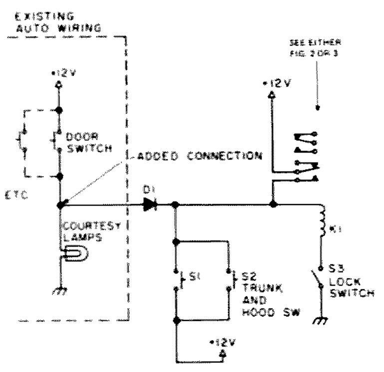

Fig. 1.

My hot rod and my Mustang were both wired the same, insofar as the courtesy lamps use switched 12 volts from the door switch while the other side of the lamp is grounded. Car manufacturers, however, being what they are, have probably made cars where the lamp is at 12 volts on one side and uses a switched ground on the other side. If your car falls in the latter category, simply reverse the grounds and 12-volt sources on the large schematic (not the two smaller alarm schematics), and reverse the polarity of diode D1. I have made provision in my system for hood and trunk switches; however, any number of extra switches may be used.

Isolation diode D1 has been included to prevent the courtesy lights from coming on when the trunk or hood switch is closed. The size of this diode is not very critical, but it should be at least 25 V piv and have a current rating capable of handling the relay coil. Notice the configuration of the latching circuit for relay K1. This corrected design ensures that the relay will latch by positively holding the relay closed for as long as a switch is closed, which will be more than long enough for the armature to contact its latching contact. Mr. Helvey's problem with the relay buzzing rather than latching is not due to a defective relay, but rather to trying to have the relay do something it wasn't designed to do.

Two different methods of activating an alarm device are shown in my schematic: 1) using the existing car horns, where the

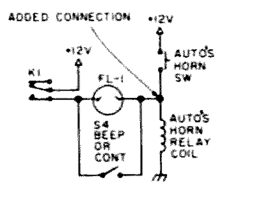

Fig. 2. For use with existing car horns with horn relay.

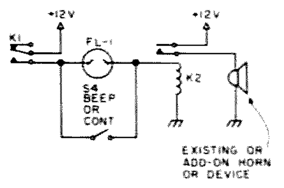

Fig. 3. For use with existing horns without horn relay or to use sirens, bells, or add-on horn.

horns are operated from a horn relay in the car, and 2) using the existing car horns where there is no horn relay (as in the case of most mid-60s Ford products) or for using a siren, bell, add-on horn, etc. Both above circuits are shown with a heavy-duty automotive flasher installed to provide a beeping alarm, rather than a continuous tone. A switch (S4) is included to change from beeping to continuous tone. If not desired, this feature may of course be deleted entirely, thereby eliminating S4, the flasher, and relay K2 from the circuit. K2 is required only because the large current drain of the horns will not permit the flasher to operate properly and will burn out the flasher very quickly.

One last note: Use only a 12-volt source capable of supplying high current (cigarette lighter, battery terminal, etc.), and use a heavy-gauge wire for all wiring. This will prevent an electrical fire, which in a car is very dangerous■

Parts List

D1	50 V 3 A silicon rectifier (Radio Shack 276-1141)	$ .69
FL1	Tung Sol 552 heavy-duty flasher (Auto Parts Store)	2.50
K1, K2	DPDT 12 V relay 10 A contacts minimum (275-208)	4.99; 9.98
S1, S2	Contact switch (for trunk and hood) (275-513)	1.49; 2.98
S3	SPST locking switch and key (275-511)	7.95
S4	SPST toggle switch (mode selection) (275-701)	.99

Build An Economy Zener Checker

—versatile test rig

Why not do it right?

The device shown in Fig. 1 was developed to check zener diodes but it has also been found useful for other purposes.

With no load across the alligator clips, the panel meter will read about 50 volts. With a *silicon* rectifier across the clips, the meter will still read 50 volts for one position of the switch but only .6 volt for the other position. Note that the switch is cross-connected to provide voltage reversal across the diode.

When the alligator clips are connected to a *zener* diode, the meter will read .6 volt for one position of the switch, but for the other position it will read the rated zener voltage up to a maximum of 50 volts.

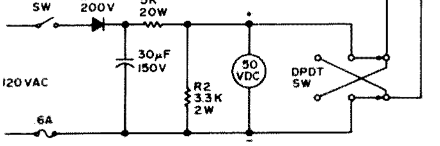

Fig. 1. Zener checker schematic diagram.

A third use is to check the total forward voltage across a string of series-connected rectifiers without applying power. This would be about .6 volt per rectifier. This check could not be made with most VOMs because their ohmmeter source voltage is not high enough.

This device *should not* be used to check *germanium* diodes unless the supply voltage is reduced. This can be done by forward biasing a silicon rectifier to obtain a .6-volt source. Then the germanium can be connected across the .6-volt source in both forward and reverse directions to see if the meter reading will drop to .2 volt in the conducting direction.

A 50-volt panel meter is probably optimum for this checker. However, other voltages could be used if the values of R1 and R2 are changed■

Alaskan Adventure
—stalking the elusive KL7

If you crank up your perseverance, you can WAS.

Yep, I got Alaska! After a solid year of frustration, anxiety, and keen disappointment, I finally corralled a KL7 station.

I believe *Reader's Digest* said that Alaska has something like thirty-seven million acres of land, and the *Callbook* shows something like fifteen hundred amateur radio stations having KL7 calls . . . so it looks like getting Alaska would be about as hard as hitting Texas with a seven and a half gallon hat.

Well, believe me, it ain't! The first thing I did was set up a sked with a station at the North Pole. I had already worked Hawaii and Australia, plus a few other DX points of interest, so, with a sked, things would be easy and I could spend more time on Delaware and the Dakotas. But the sked just didn't come off as expected . . . three times each week KL7IUM and I would toss CQs back and forth at each other, but none of them made connections in a faithful six months of effort. One by one, the other states came dropping in until I was down to Delaware and Alaska . . . and try as I would, I just couldn't find the range.

A funny thing happened on the way to WAS, however . . . I was glued to the CW bands, and one day I heard a CQ that ended: "CQ, CQ, CQ de LA WARE!" I went back to him, not being sure where LA was, nor what country had calls without numbers. The *Callbook* said that LA was Norway, but they had a number after the "LA" . . . so I assumed I had read 3 into a W . . . missing a few dits in the translation. Could happen! So I called and called . . . no reply. Then I told my friend WB5WDD about it, and he said he had heard the same station but couldn't get it to come back. We agreed it was Norway . . . and let it go at that. Finally I landed a Delaware station, and it was then and only then that I realized the CQ I heard was FOR Delaware and not FROM Norway. It could happen to anyone!

But, after concentration on Alaska, I began to hear a few KL7 stations . . . one of them coming in quite clearly on a Sunday afternoon. He called CQ South America, so I waited through several of his calls until finally I assumed he would not get his desired station. Then I called him and anxiously awaited his return call. It came like this: "Can't you hear? I am calling South America!" So there was lesson number XX on CQ courtesy . . . but I kept listening and dialing. One evening I heard a truck driver, mobile in California, rag chewing with a strong KL7 station . . . so I waited . . . and waited . . . and waited . . . not daring to holler "break" after the previous experience. They gabbed a good half hour, and the truck driver, who evidently had not read the book on ham courtesy, either, closed by saying, "I have a buddy tuned in on us now that would like to have a word with you . . . so I'll be . . . etc., etc." And the buddy took over until the band closed! Well, it was important . . . the buddy was trying out a new rig, and he wanted the opinion of this stranger in Fairbanks on whether he should buy the rig or not!

Finally, in desperation, I decided that the next KL7 I heard would either pitch me out on my ear . . . or QSL! And then it came . . . again, a strong station in KL7-land hooked up with a California ham . . . and I sat through the usual routine of statistics before timidly shouting "break" plus other pertinent data that I thought would get

me through. There was a short silence and KL7 said, "I believe we had a breaker . . . come on in, breaker!"

Here was the chance I had been so long waiting for . . . and behold, my voice almost failed me! Finally I got it out: "KL7ABC, this is WB5WDG, Muskogee, Oklahoma. Do you copy?"

There was an exciting few seconds of dead silence, and then California said, "I believe he is calling you, KL7."

Then KL7 said, "No, I think he was calling you." and with that, they went back to their aforementioned QSO and never paid me another bit of attention. I snapped off the rig, snapped at my XYL, and told her where they could put Alaska if Russia ever wanted her back . . . and went to bed, only to roll and toss and count caribou, grizzlies, fjords, and permafrost.

But the final blow came a couple weeks ago when KL7 came in quite clearly, slowly, and with a hesitating dahdididahdit followed by SA . . . so, naturally, I assumed that this was a Novice newly upgraded who was trying out his new wings. I went back to him in fear and trembling, hoping that this was it. And it was . . . he heard me and came back loud and clear. A real live KL7 . . . and he was answering my call . . . at last, the big hunt was over. I was so excited that I almost missed his QTH when he gave it as Ft. Bragg, North Carolina. He had been transferred from a military base in Alaska and was still using his KL7 call . . . the SA I had heard after the dahdididahdit was not an SA at all, but a four. Your ears hear what you want them to hear.

But enough of that stuff . . . quitting never gets it . . . and I just didn't quit. Quite by accident, I heard a QSO that ended identifying itself as having a treasured Alaska station as one of the participants. Again I waited patiently until it ended, and I swung in behind the finale with my call. Believe it or not, the KL7 answered.

At last, my luck had changed and I was ready to apply for my WAS award. His signal was strong . . . his fist was great . . . and everything was deathly quiet. He acknowledged my call, gave me his name, and then started with his QTH—just as a 4-land station with a million-Watt linear started his big CQ, almost knocking my cans from my ears. I ditted a few thousand times and he stopped just as the lad in Anchorage was telling me that he had to get to work, but would answer my QSL as soon as he got it. And that ended that . . . thanks to the million-Watter in orange country.

Only this time I was ready. This had happened to me before . . . many times . . . so I was prepared. While I was listening to the KL7 QSO, I was copying his data as he sent it to the former recipient . . . and even though Florida knocked the orange juice out of my coax, I was ready with the proper address and now have my QSL merrily on its way to Anchorage with an SASE enclosed!

Why didn't I refer to the *Callbook*? Well, this lad had already said that he was too new to be in the latest edition of the *Callbook* and he had to get his QSLs in care of his dad, who was in the book! Practice may not make perfect . . . but it helps. ■

The Last DXpedition

—"QTH hr is Purgatory"

What the devil is going on here?

This old-timer was one-in-a-million, with a personal history dedicated to amateur radio. He was the envy of operators the world over. He held more certificates than the average ham ever knew existed, was winner of numerous contests and citations from all over the world for amateur radio services above and far beyond the call of duty, and was designer and builder of practically every type of radio equipment from the spark-gap days on up. This old-timer had just expressed his last "73" along with his final "dah-dit-dah." In simple words, he died.

He awakened, feeling no pain, and discovered he was lying on a very comfortable, elaborate bed, in a gorgeous room which was permeated by the faint odor of burning sulphur. "Oh, brother," sighed the old-timer, "I knew this would happen to me. I should have been more careful to always stay within the legal bands. I knew I was wrong in using that 'California Kilowatt' so often, and I should not have worked those guys with the HS, XU, XV, 3W8, and 8F calls. Yes, I'm confined to eternal damnation!"

"Just a minute there, my friend. Don't be upset about what happened to you." Jumping from his bed, the old-timer found himself face-to-face with a man who was reddish of face and the epitome of sartorial splendor in his superbly tailored suit, bright red socks, and foot-long cigar. The old-timer could plainly see the horn-like protrusions, all polished and gleaming, near the top of the man's head, and even the shadow of a tail extended from his rear. "Allow me to introduce myself. I am lovingly called Satan by my many admirers and I welcome you to Purgatory. Now, don't get yourself all uptight about things you heard concerning me and my home from those narrow-minded people up there where you used to live. I've been given a bad press all my life, and I honestly don't feel I deserve such humiliating treatment. They don't like me up there for some reason, and they sure paint a black picture of Hell. Now, don't misunderstand me—it's Hell down here alright, but we still have plenty going for us, as you'll soon discover. Here, have a glass of 20-year-old bourbon, a fine cigar, and pull up a chair. Tell me all about yourself, you lucky man!"

Before the old-timer had time to collect his thoughts, Satan started in again. "Look, pal, I'm going to try to make you like it down here. Sure it's Hell, but just for openers, tell me what you like the best. Do you want a dozen or so beautiful, sexy gals—or maybe you'd like to become a millionaire? Is it just hunting, fishing, and yachting you like? Tell me what 'turns you on' and it's yours, absolutely free of charge, with no strings attached."

"Well, Mr. Satan," replied the old-timer, "up there I was one hell, oh, pardon me, of a ham radio operator, and I thought just maybe you'd have . . . "

"A ham radio operator!" screamed Satan. "Why the hell didn't you say so in the first place! Quickly, come with me." Satan then rushed the old-timer outside to a warehouse, unlocked the door, and said, "We'll start with your tower. Here's a nice medium height one of about 500 feet, OK?"

"Wow!" yelled the old-timer. "These are built better than the commercial towers up there. You sure there's no catch to this?"

"Aw, come on, pal," replied Satan. "Would I fool you when you're going to be my guest for quite some time? Why shouldn't I try to please you with the best of everything just to make you happy? Sure, it's Hell down here, as I said before, but we still have much more to offer a nice guy like you. Now, let's get some antennas up. How's this—a simple Christmas tree of rotary beams, simple 10-element beams for every band? I'll have them erected immediately."

"Yes, but what am I going to do for a transmitter and receiver?" queried the skeptical old-timer.

"Never fear, friend, Satan is here. Take a look and pick up any of these." Here was a room filled with every late model transmitter and receiver, all in sealed cartons. The old-timer was dumbfounded, as he had never owned any equipment that wasn't "home brewed."

"Wait a minute, friend," said Satan. "Pick up a good linear while you are at it. And by the way," he whispered, edging over to the old-timer, "how about one of my special 'Satanic Kilowatts' that makes those 'California Kilowatts' up there sound like peanut whistles? Here's a great new 10 kW job.

"Sure, this is Hell, but answer me truthfully, did anyone up there ever offer a nice guy like you so much for free with absolutely no strings attached?"

The old-timer was absolutely at a loss for words. Having scrounged all his life for every dime to buy used parts to build anything he ever operated, he never dreamed he would be so fortunate as to have such magnificent appliances to operate for all eternity. "Let's get this set up!" yelled the old-timer. "I just can't wait to get on the air!"

"Certainly," said Satan. With a wave of his smoking hand, there was a loud clap of thunder and a puff of sulphur-ridden smoke, and the old-timer found himself in a shack fit for a king, with everything properly set up.

"Great, great, absolutely beyond belief!" cried the old-timer. I just don't know how to thank you enough. I'm going on the air to tell everybody up there the true story of you and your kindness, Mr. Satan. I'll tell them the absolute truth about the goodies you have to offer everyone. By the way, where do I plug in this magnificent equipment?"

"Well, my friend," replied Satan as he hastily headed for the door, "that's the hell of it—we have no electricity!"■

An Audio Morse Memory

—got a tape recorder?

Listen to your own fist—and learn.

The tape recorder decoder (Fig. 1) can be very useful and is easy to duplicate. It converts an audio signal to dc to key a relay. Code can be recorded on a tape recorder, then played back through the decoder, thus keying a transmitter, monitor, or both. Works just dandy for a "CQ" tape or a "CQ field day" tape. CW can also be recorded from a receiver and then played back to key your transmitter, letting a fellow amateur hear his own fist! A delayed test-transmission with a timer can also be arranged, allowing you to check signal quality from a friend's shack.

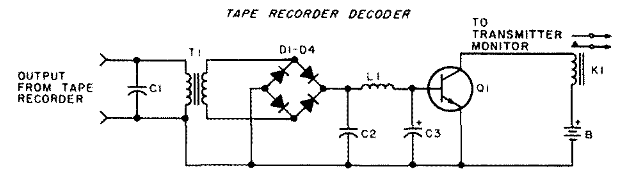

Fig. 1. Tape recorder decoder schematic diagram.

Parts List for Tape Recorder Decoder

Q1—For maximum sensitivity, a high-gain transistor such as a 2N447A (gain of 200) should be used. But any transistor of reasonable gain is OK (2N338, 2N3641, 2N3843, etc.). A PNP transistor can be used as easily by reversing the polarity at the battery and C3 (2N1307, 2N404, 2N408, 2N1025 with a gain of 100).

C1—.001 to .005 uF rf bypass.

C2—.1 to .25 uF disc ceramic, mylar, or electrolytic (6 V).

L1 — .5 H choke. A toroid is best because of its small size and low losses. The value is not critical and can be replaced with a 68- to 100-Ohm resistor, though performance is degraded slightly when demodulating low frequencies.

C3—1 uF to 2 uF, 3 V electrolytic.

T1—miniature transistor audio output transformer with primary of 8 Ohms (to match tape recorder output) and a secondary of 500 to 1000 Ohms.

D1-D4—1N34 or equivalent. Just about any small-signal, germanium diode will work.

K1—reed relay with 3- to 6-volt coil. A 10-Watt reed relay with coil can be bought at Lafayette Radio, or a range of relays, with and without coils, can be obtained at suppliers.

B—battery, 3 to 6 V.

None of the part values are critical. The volume control setting on playback and record will have to be adjusted to obtain the best results. Playback volume should be as low as possible to prevent background noise from causing odd clicks, or overloading from causing mushy characters.■

The Amazing Active Attenuator

—can you find a use for it?

The op amp is the answer.

I'm sure, by now, you have heard of many uses for op amps. But did you know that they can be used as attenuators? For some uses, they are better than attenuators consisting of only resistors. While the principle is very simple, I have not seen much mention of it in the various electronic magazines.

In an inverting op amp amplifier, as shown in Fig. 1, the gain can be varied from the open loop gain down to a gain of one. This gain is determined by the equation R_f/R_{in}, where R_f is the resistor from the output to the input and R_{in} is the resistor from the driving source to the input of the op amp (Fig. 1). Now, what happens if R_{in} becomes greater than R_f? To save you the trouble of running this experiment, the answer is that there is a loss from input to output and the circuit becomes what I call an active attenuator.

There are, unfortunately, some disadvantages to this attenuator. The first problem is that an active component, along with its associated power supply, is required. Also, frequency response is restricted to the bandwidth of this active component. Next, you must remember that this circuit inverts, so if you are using it for dc, you will get a negative voltage out if you feed in a positive voltage and vice versa.

Now, for the advantages. The output of this active attenuator, as in any op amp amplifier, is a low impedance (independent of resistor values). This means that any loading (within reason) of the output will not change the output voltage. Also, it is great for driving long, unshielded wires without the worry of hum. Also, although I am not yet sure what it is useful for, you can use this circuit as a summing attenuator. This is done by using different input resistors for each input desired. Fig. 2 gives the details.

Here are a few things to watch out for: First, the amplifier configuration must be inverting because a non-inverting op amp amplifier has a minimum gain of one no matter what. Second, the input impedance is equal to R_{in}. So, when calculating the resistor values, choose R_{in} first, so that it is equal to the desired input impedance. Then choose R_f for the desired attenuation. Using this procedure, the resistor equation can be rearranged as $R_f = R_{in} \div$ desired attenuation. Also, make sure that the op amp is still useful at the desired frequency of operation. One thing that I am interested in knowing is what happens to the open-loop frequency response when the circuit is used as an attenuator. I know that as the gain of an op amp increases, the frequency response drops, so with an active attenuator, does the frequency response increase?

Well, I hope that you can put this information to use. I have not given too many details because most of the information required can be found in many magazine articles and books dealing with using op amps. I have found the *IC Op-Amp Cookbook* by Walter G. Jung (Howard W. Sams & Co.) especially useful. If you come up with some new data or uses for the active attenuator, please let me know about it. If nothing else, you can use this circuit as an answer to those people who go around talking about "passive amplifiers and active attenuators." ■

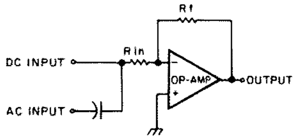

Fig. 1. Circuit for the active attenuator. $V_{out} = (R_f/R_{in})V_{in}$ and $R_{in} = R_f \times$ desired attenuation.

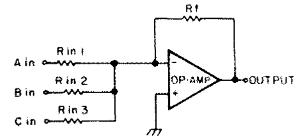

Fig. 2. Circuit for summing attenuator. Attenuation of $A_{in} = R_f/R_{in}1$, $B_{in} = R_f/R_{in}2$, and $C_{in} = R_f/R_{in}3$.

La Mesa CA 92041

A Single IC Time Machine

—amazing clock

You name it—this does it.

Both clocks set up and operating. The small clock is on GMT, the other on local time. The radio is connected to the alarm output of the larger clock.

How would you like an electronic clock with options from the following assortment of features?

Single-chip operation
Fluorescent direct drive
Simple forward or reverse time setting
4-digit nonmultiplexed display
Am/pm and 1 Hz activity indicator
50 or 60 Hz timebase operation
Three-function wake select (radio tone, radio, followed by tone in 8 minutes)
Count inhibit
Power-up clear
Leading zero suppression for tens of hours
Month-date or date-month format
A second alarm time
LED direct drive (10 mA/segment)
Low-voltage standby allows 9-volt battery backup
Intensity control
Slow-up circuitry eliminates RFI
12- or 24-hour display format
24-hour alarm
Variable sleep (1 to 59 minutes)
Seconds display

INSTRUCTIONS

1. To adjust, remove a screw on each side and remove the cover. As viewed from the rear, left to right, there are 6 switches as follows:

#1 (Red toggle)	Set hours/month
#2 (Green toggle)	Set minutes/day
#3 Slide switch	Inhibit/run
#4 Slide switch	Spare
#5 Slide switch	Alarm select—UP alarm #2, DOWN alarm #1
#6 Slide switch	Display format—UP 24 hours, DOWN 12 hours

Note: In 12-hour mode, pm is indicated when 3 bars appear In the first digit position.

2. On initial light-off, all time functions will read 0:00, colon on or off, date will indicate 12 31, and seconds 00. To start the clock, momentarily place switch #2 (green toggle) in the advance position; seconds will start counting and the colon will flash. (Minutes may be set at this time if desired.)

3. To synchronize (to WWV or a time-tick), place switch #3 in its up position, stopping the clock as indicated by the absence of a colon and 00 seconds. At the instant of the "00 seconds" pulse from WWV or other time source, depress switch #3, restarting the clock.

Note: Step #2 must be performed first, after initial light-off.

4. Place function switch on LOCAL and set time:
   (a) To set hours, use switch #1 (red toggle)—UP advances; DOWN decrements; and MID-POSITION is the normal run position.
   (b) To set minutes, use switch #2 (green toggle) as in (a) above.

5. Place function switch on zone, alarm 1, or alarm 2, and set the desired time as in step 4(a) and (b). Repeat for each desired function.

6. Place function switch on DATE and set the desired date, using the #1 toggle for month and #2 toggle for the day.

Note: After the seconds have been initially synchronized, any and all times (and/or dates) may be changed at will. No further synchronization is required unless the timebase is gaining or losing time—or the clock is accidentally stopped when changing power sources.

7. To use the alarm(s), select the desired alarm with switch #5, and then place the front panel alarm switch to ON. When the alarm energizes, it may be stopped for 10 minutes by pressing SNOOZE, or by momentarily turning off the alarm switch. (A momentary turn-off rearms the alarm to energize at the designated time 24 hours later.)

Notes: SNOOZE inhibits the alarm for 10 minutes from the time it is pressed (not from the time entered), e.g., if the alarm is set for 06:00 and is "snoozed" at 06:03, it re-energizes at 06:13. This may be repeated indefinitely and makes the feature amenable for use as a 10-minute timer during long-winded QSOs. Also, if the display is blanked, the alarm feature will activate but will not sound off until the display is unblanked, if done within 1 hour of the time set. (Unless the snooze button is pressed, the alarm operates for an hour and then resets itself should the alarm circuit be on but the clock unattended.)

8. On the right side of the front panel are two slide switches which control the illumination level of the LEDs. The first blanks or unblanks the display; in the blank position, the alarm output is also made inoperative (see step 7, above). The second (outboard) switch controls the display illumination level: HI for daytime viewing and LO for nighttime viewing.

OPERATION

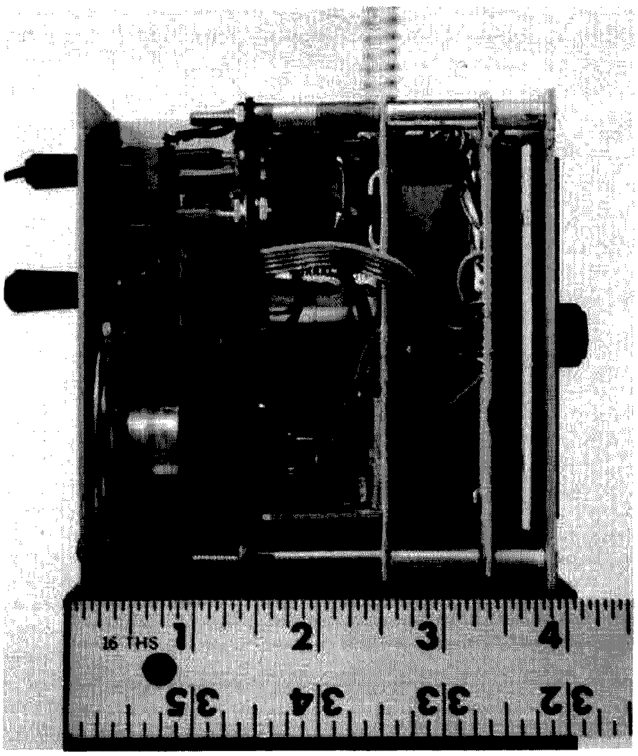
1. This clock is designed to operate from a number of power sources, 9 to 13 V dc or 6 to 9 V ac at the power input jack, without regard for polarity, or on a 9-volt transistor battery internally mounted. A small earphone-type jack is in parallel with the internal battery and may be used to (a) parallel the internal battery with an external battery while exchanging the internal battery, (b) provide a convenient test point for measuring the internal battery voltage condition, or (c) if necessary, be used as a recharge point for the internal battery.

2. The input to the power supply is a bridge rectifier which will accept ac or dc voltages of either polarity. A -5-volt regulator (7905) provides the LED voltage and a regulated 5-volt source for the internal crystal timebase. All circuits have been isolated from the case; therefore, it is safe to use this instrument in a car, using its battery connected to the power jack without regard to polarity. Caution: The shaft of the function switch is at circuit ground (+) and *must* have a plastic knob. Use of a metallic knob will invalidate the preceding statement.

3. The crystal timebase adjustment capacitor has been paralleled with a small piston-type capacitor to provide a "fine" adjustment, and is accessible via a small hole in the back skirt below the alarm speaker.

4. In operation, this unit draws current from the power source as follows:

7 mA — Illumination blanked
26 mA — Illumination LO
160 mA — Illumination HI



Battery version, top view.

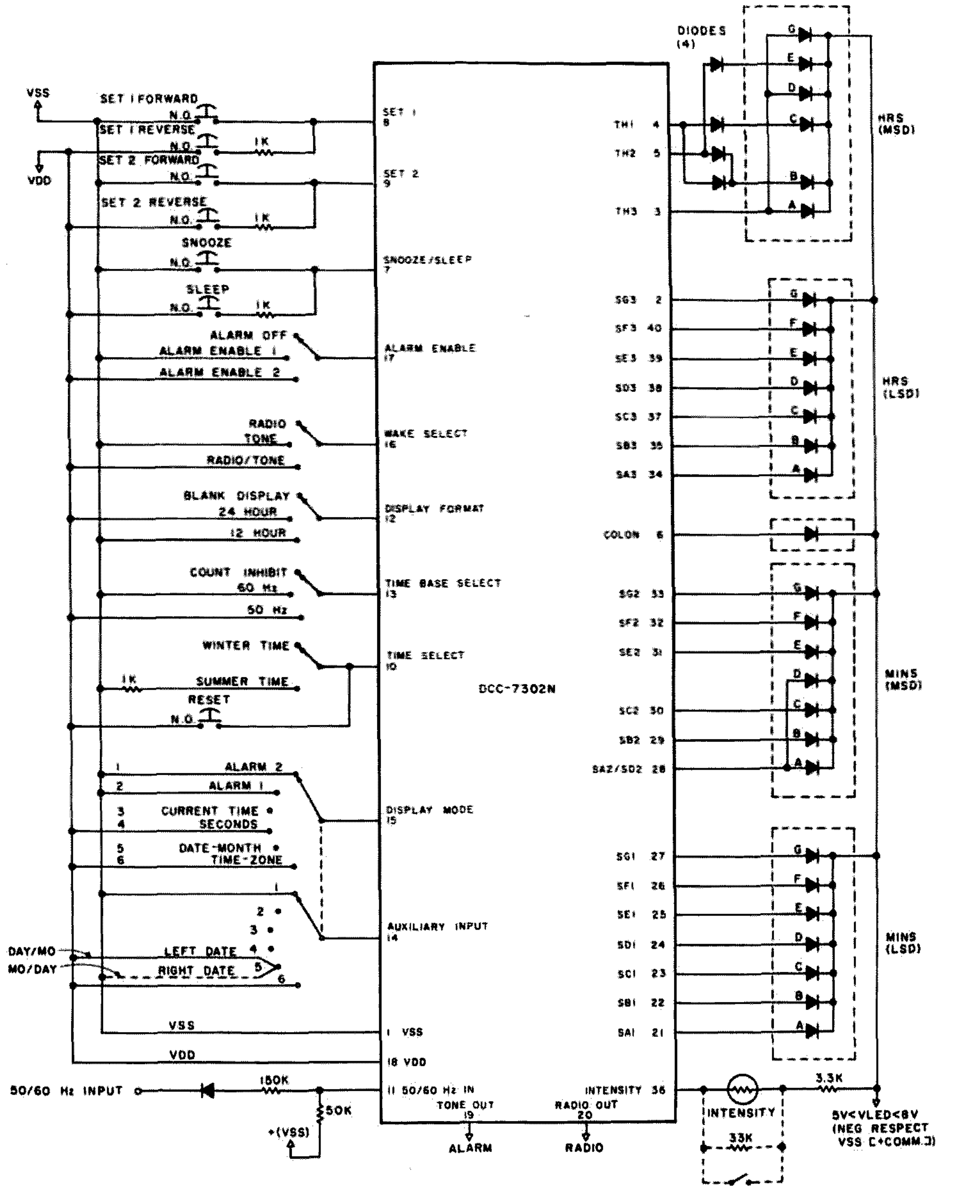


Fig. 1. Generalized circuit (24-hour or date left display format) — a modified drawing to show the 12- or 24-hour option, the 50/60 Hz option, and the manual intensity control option.

Summer/winter time switch for Daylight Savings Time
Brownout indication
Four-year calendar
One time zone register

Would you like to use it independently of power lines, as well — possibly in your car or in foreign countries when you travel on 230/115 V, 50 or 60 Hz?

If you desire a clock with the above listed features, the DCC-7302N clock chip comes in a kit, available with fluorescent display, for about $30. In order to add options, read on. The chips are available for about $6.00 and an LED 4-digit display for about $10, or you can fabricate your own display from individual LED readouts.

I have produced 2 clocks around the 7302N chip. One is designed to operate from 115/230 V, 50/60 Hz power lines and includes many of the published chip options. The second is designed to be operated from either a battery source or a filament transformer — in this, a bonus was obtained when it was discovered that the clock will function nicely on 9 V or less, and the battery drain may be minimized by using low illumination or a blanked display as much as possible. Blanked, the total current is 7 mA; at minimum illumination, it is 26 mA, and, at maximum illumination, 160 mA (using a 9 V source).

The 115/230-volt version uses the power lines as a timebase and has most of my desired options, as indicated in the drawings.

The battery-operated version uses a crystal timebase sold by S. D. Sales, and several options were deleted to conserve on space and the number of switches required. A 7905 negative regulator IC chip is used in this unit to provide 5 V regulated for the timebase and the supply voltage for the LEDs.

Caution: Although these chips use a positive ground

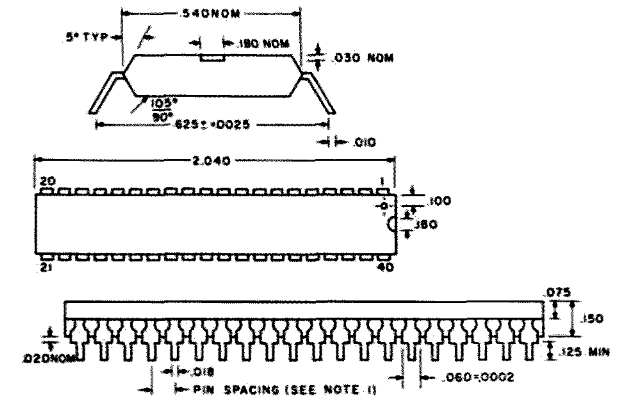

Fig. 2. The pin spacing is 0.100 between centerlines. Each pin centerline is located within ±.0010 of its true longitudinal position relative to pins 1 and 40.

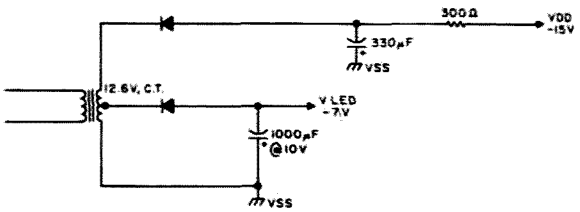

Fig. 3. Recommended power supply for LED operation.

(common), the LED display must be of the common cathode configuration.

PC Board Preparation

Lay out the circuits on graph paper, full scale, 10 lines to the inch, making a template. The template is then taped to the copper side of the PC board stock and each hole point lightly punched through the template. Remove the template and clean the copper with scouring powder and/or a steel wool soap pad, rinsing

Input function	V_{SS}	Open	V_{DD}	Aux input
Display mode	alarm 1	current time	seconds	open
Display mode	alarm 2	month-date		V_{SS}
Display mode		date-month	time zone	V_{DD}
Set 1	forward		reverse	N.A.
Set 2	forward		reverse	N.A.
Timebase select	60 Hz	count inhibit	50 Hz	N.A.
Display format	12 hour	blank	24 hour	N.A.
Wake select	tone	radio	Radio and tone	N.A.
Alarm enable	enable 1	off	enable 2	N.A.
Snooze/sleep	snooze		sleep	N.A.
Time select	summer	winter	reset	N.A.

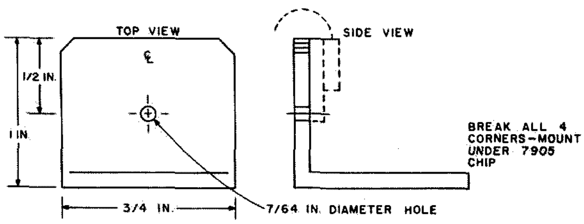

Fig. 12. Heat sink detail. Use 1" x 1" x 1/16" aluminum angle cut ¾" wide or fabricate it from aluminum or copper stock.

and drying each PC board thoroughly.

After the PC board is dry, use a wide-tip permanent marking pen and draw a wide line (about ¼") through all close-spaced contact points (20 on each side of the chip and others). Then, using a straightedge and a scribe, remove about 1/64" of the ink from between each of the contact points. Using a narrow etch-resist pen, draw a circle around the individual contact points (those separated by more than 0.1"), and connect the various contact points as indicated on the template. Use care not to soil the copper during this process. After all contact points have been correctly and properly connected, use the wide marker pen and fill in as much of the unused copper as possible to reduce the amount of copper that has to be etched off. This will speed up the etching and prolong the life of the etchant. In the battery version, remove the copper around the corner holes and the function switch mounting hole.

Etch the PC boards with your favorite etchant.

Note: There are several permanent marking pens on the market that will satisfactorily perform as etch-resist pens: El Marko™ and Marks-a-lot™ are examples that have been used here. If in doubt, try your favorite on a scrap of PC board. These pens are much less expensive than the etch-resist pens available from your friendly Radio Shack or other dealer.

Construction

All PC boards should be the same size for mounting ease, unless you wish to mount the programming board separately, as in the case of the 115/230 V version.

Check over the features

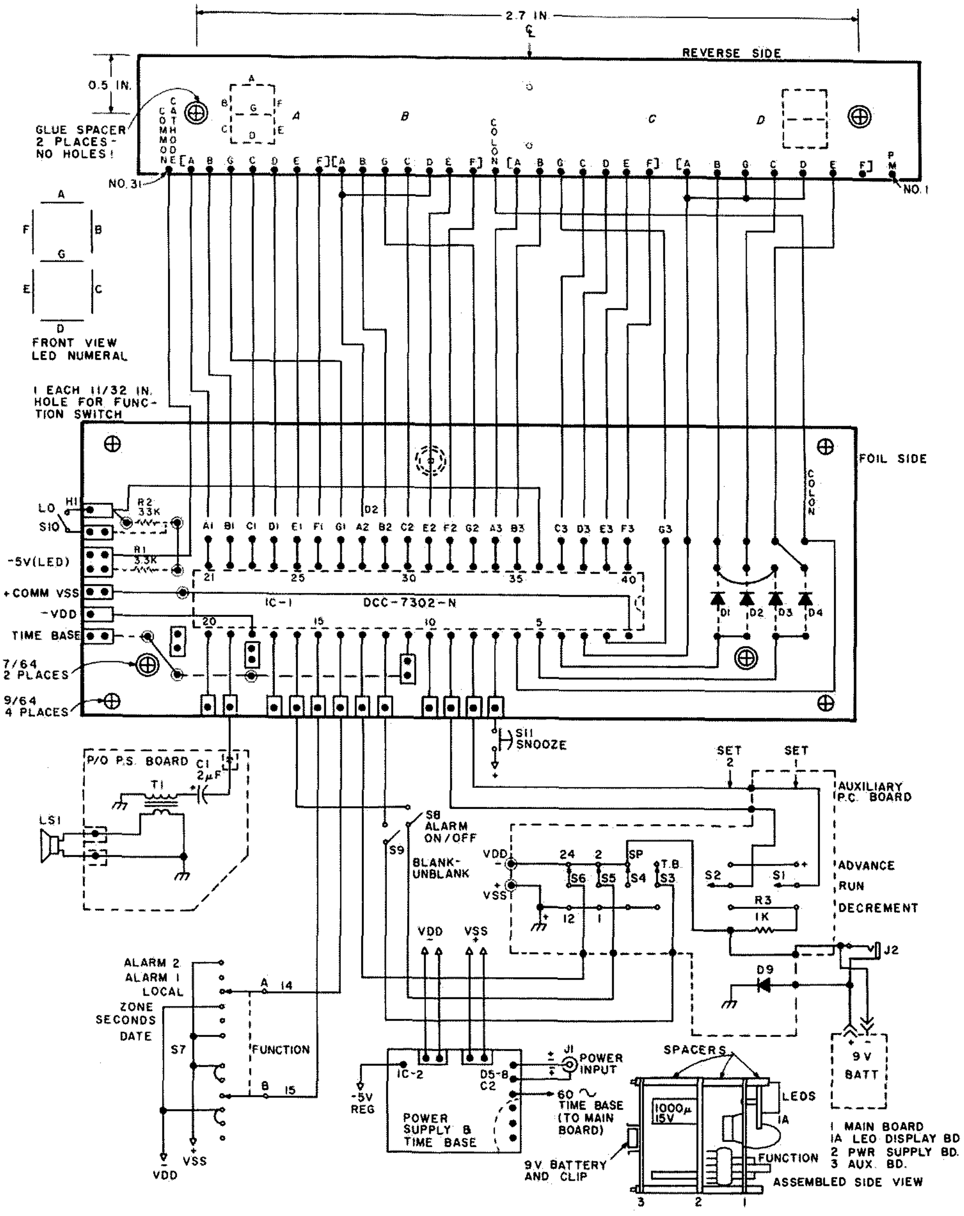

Fig. 13. Wiring arrangement used for the battery version. J1 and J2 must be isolated from the cabinet chassis.

and decide which ones you need and which ones you can live without. Then determine how many switches you need. Time can be set with push-buttons, but, to conserve space, use SPDT miniature toggle switches with center-off. For economy, use single-pole slide switches where possible. Minimize the number of front panel switches. In the 115/230 V version, I used 6 push-button switches, 5 SPDT center-off toggle switches, 2 SPST slide switches, and 1 DPDT slide switch. In the battery version, it came out 2 SPDT center-off toggles, 1 push-button, and 7 SPDT slide switches, of which one is a spare and 4 are used in SPST functions.

Two problems were encountered in the timebase inputs. In the 115/230 V version, the chip would not initially clock. A copy of the kit schematic was obtained, and it indicated that pin 11 was biased back to common via a 150k Ohm resistor. This cured the clock problem but created another – the chip was clocking at 2 pulses per second rather than one pulse per second. A diode cured that. In the battery version, I found that pin 11 would drive directly off the output of the timebase without a diode, an isolation capacitor, or isolation resistor. However, I found that if the filter capacitor and the 7905 chip were not adjacent on the PC board, it would be necessary to place about 0.1 uF across the input to that chip to stabilize the output of the timebase.

A socket for the 7302N chip is recommended but not necessary. When drilling the PC board, use care, and, if possible, use special drills* for glass epoxy boards. Use nothing larger than a #65 drill, except at the edge points where wire connections are made, where a #60 drill is more correct. Of course, the hardware holes must be of the correct sizes to accommodate the screw sizes used. If a drill press is not available, be very careful with a hand drill or it will drift or make slanted holes, and aligning 40 pins of a chip or socket is no fun under those conditions (experience speaketh).

*Special drills are available from: Ford Cutting Tools, M.A. Ford Mfg. Co., Inc., Davenport IA, or Tools & Metals, 301 N. Johnson, El Cajon CA 92020.

The 2-pole 6-position non-shorting function switch may be mounted on the same PC board as the chip. The LED display and the chip PC are mounted back to back with a ¼" spacer between them (see drawings for details). Locate the positions on the back of the display that correspond to the positions on the template for the main board (with the chip). Thread the spacers for #4-40 screws, and use Super Glue™ (or its equivalent) to bond them in position.

I also used Super Glue to secure all slide switches in position, and, in the battery version, the battery clip was secured similarly. If done right, a good bonding is affected; if done wrong, try, try again (it took 3 passes for the battery clip to hang in there).

6-32 x 3" screws were used to mount the PC boards into the cabinets, using spacers and the front panel for support. If necessary, ¼" Plexiglas™ tubing may be used to fabricate the desired spacers. The i.d. is slightly smaller than a 6-32 thread and can be either tapped or drilled out – for ease of assembly and disassembly, unthreaded spacers are recommended.

Use care in locating the 4 mounting holes for the 6-32 x 3" screws, the openings for the display, and the shaft of the function switch on the front panel. In the battery version, provide an insulated mounting for the switch or insulate the shaft with shrink tubing, and be sure there is no contact between the shaft and the case (this has been

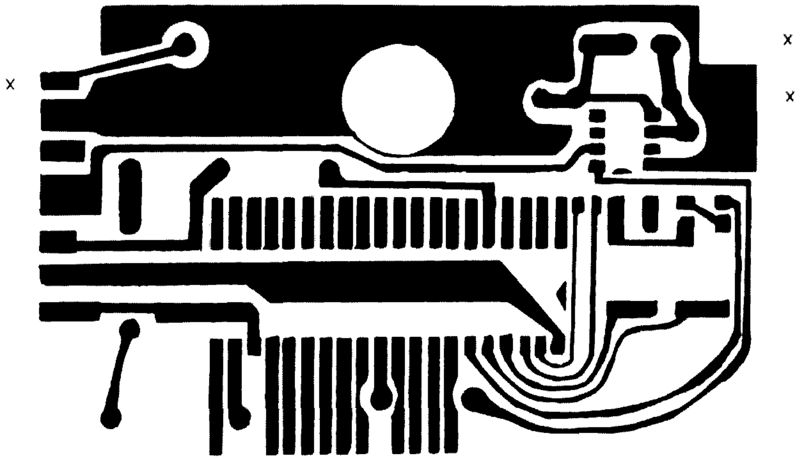

Fig 14(a). Main circuit board – PC board.

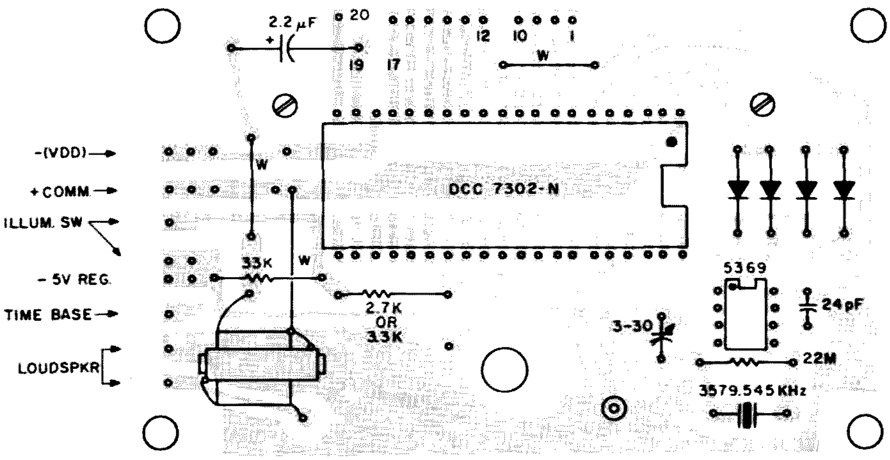

Fig. 14(b). Main circuit board – component layout.

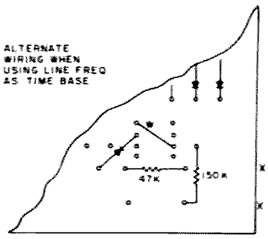

Fig. 14(c). Alternate wiring when using line frequency as timebase.

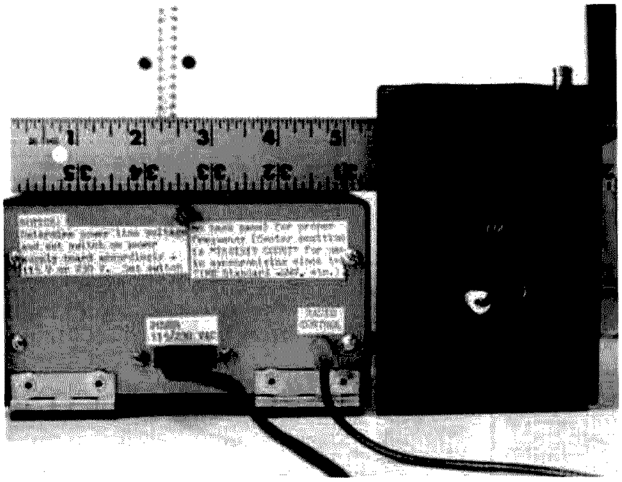

Ac operated version, rear view.

corrected in the included template drawing).

The illumination control is a 33k Ohm resistor with an SPST switch in parallel to add or subtract the 33k to or from the circuit. If desired, the switch and resistor may be replaced with either a 30k Ohm variable resistor or a photocell control of about 30k Ohms maximum resistance.

At this writing, it has been determined that the battery-operated unit is hard on 9 V transistor batteries, in spite of its low drain in the "low" or "blanked" conditions. A Duracell™ only lasted about 20 hours under a 26 mA load; a regular carbon-zinc battery lasted about 18 hours (both new batteries). Although the clock works satisfactorily on a 9 V battery charger, I learned that the circuit "loads" the charger to about 7.8 volts, and a new battery inside the unit will supply power to the clock, in parallel, until it is at or below the input voltage from the charger.

When the clock is on the internal battery, it will continue to function (blanked or low) at terminal voltages below 7.0 volts, but disturbing the input power (paralleling the battery or applying an external supply) can and does cause glitches, if not done carefully. When glitches are introduced, the displays become random – like showing 65 seconds, or a 3 in the tens-of-hours column, or beeping the alarm tone when the alarm is turned off. Under these conditions, the best cure is to remove power completely and restore the correct voltage level; the clock needed resetting anyway.

If it is desired to use the pm indicator in the 12-hour mode (rather than display 3 bars), the 12/24-hour selector will have to be a DPDT (center-off) switch, and the date format will have to be the American style (month/day). Similarly, if only the 12-hour option is desired, the month/day format must be used in order to access the pm indicator, as the 3-bar output required for a 2 or a 3 is also the pm indicator in the 12-hour mode, and no digit greater than a "1" can be

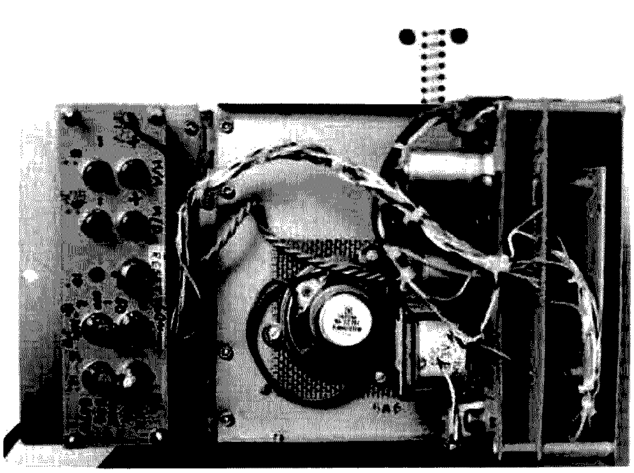
tolerated in the tens-of-hours digit when the pm indicator is desired.

The clocks were mounted in small utility boxes. The 115/230-volt version was installed in a box 3" H x 5¼" W x 6" D. The chassis was U-shaped, but the back panel (skirt) was sawed off at the bend, dressed up to allow for hinging, and hinges were installed. The programming board is mounted on this, and, when it is desired to set the clock or change the program, one thumb screw is removed and the back drops down, disclosing the programming switches. The battery version is mounted in a Ten-Tec TG34 box which is 3" H x 4¼" W x 4¼" D. It is of a double "U" construction, and the top/sides piece is removed by removing one screw on each side, exposing the interior and making the set and program switches available.

An attempt to operate the battery clock off the cigar lighter outlet in the car met with failure, causing a glitch when the car was started. A filter is proposed, consisting of a small resistor and two 12 V zener diodes back to back to act as shorts for any transients. ■



Ac operated version, top view with the rear skirt opened to disclose "program" switches.

Car Battery Charger

—junk-box special

This is the safe way.

David E. Roscoe W1DWZ
49 Cedar Street, RFD #2
East Bridgewater MA 02333

One of the most useful pieces of "junk" that can be found in any self-respecting ham's junk box is an old, but serviceable, 12-volt automotive battery. They can be very useful for bench testing, field day operation, running that mobile rig at the home QTH, jump-starting the wife's car, etc. To be maintained at the peak of their usefulness, they do require occasional recharging. After getting along for a number of years with a haphazard (and dangerous) collection of hay wire and diodes, we decided to remedy the situation. Most of the commercially available chargers did not seem to meet the requirements we wanted, so we set out to fabricate our own. We wanted one that had the capacity to put out 15 Amperes or so if needed, yet have the capability of being adjustable to 1 or 2 Amperes for a trickle charge, or to some value in between.

After experimenting briefly with series resistors and series-regulating pass transistors, these ideas were discarded as we found it difficult to dissipate such large quantities of power (and heat). While thumbing through some manufacturers' applications literature, we came upon one describing the triac and decided that this would be a really neat way to do it (Fig. 1).

A triac is basically two SCRs connected in parallel in opposite directions so that conduction is permitted during both halves of the ac sine wave. By controlling the phase and amplitude of the signal to the gate, the firing point of the triac can be controlled and, thus, the conduction angle can be varied to regulate the input power to a transformer primary. A bilateral thyristor (D1, a diac) is used in the gate circuit to provide a threshold level for firing the triac. C3 and R4 provide a transient suppression network to protect the triac from damage when the power is switched off to the transformer primary.

R1, R2, R3, C1, and C2 provide a phase-shift network for the signal being applied to the gate. R1 is selected to limit the maximum charging current at full rotation of the control pot to stay within the ratings of the rectifiers, transformer, etc., of the specific components chosen by the builder. As is true of most ham projects, we tried to use what parts we had available. Readers wishing to build this unit could substitute whatever they might have in their junk boxes for the bridge and the transformer and their unit would only be limited by the voltage and current ratings of these components. ■

Immortality for Vacuum Tubes?

—build a solid state tube saver

This circuit doesn't replace tubes—it prolongs their life!

Lewis J. Newmire K5KXM
217 South 103rd E. Ave.
Tulsa OK 74128

The deleterious effects of simultaneous application of heater and plate voltages to vacuum tubes are well known. High power transmitters have interlocks and time delays to prevent such occurrences. For reasons of economy, however, such interlocks or delays are seldom designed into consumer electronics.

The solid state circuit shown in Fig. 1 is a simple but effective 60-second B+ delay. Q1 is any SCR able to block unloaded B+ voltage and pass the required load current. Using an RCA S-2061M, this circuit will perform in power supplies up to 600 volts and 4 Amperes.

This circuit is not a perfect switch. It has a voltage drop when on of about 1 volt and a "leakage" current when off equal to (Volts$_B$ unloaded /30 in mA. This "leakage" current of a few milliamperes limits plate voltages in most applications to only a few volts. The 10-Watt resistor is operated at full rating with a B+ of 600 volts, but only for 60 seconds at each turn-on.

Wire the B-delay into the power supply as shown in Fig. 2. The + end of the switch is connected to the input filter capacitor. All other wires except the one from the rectifier(s) must be removed from this capacitor and connected to the − end of the switch.

The B-delay may be installed in all types of vacuum tube equipment including receivers, transmitters, instruments, and TV receivers. Note: In a color TV receiver, the automatic degaussing may be visible on the screen for a few seconds after B+ is switched. The original B-delay used an RCA 40812 SCR. It has been operating in my black and white TV for 6 years, during which not a single tube has been replaced.■

The Hot Mugger X1

— coffee drinkers, rejoice!

There is no such thing as a cold drink.

Ever since Wayne Green's editorial in the July, 1977, issue of *73*, I have been thinking about a coffee warmer. He gave some ideas on how to make one and also said that it should be a real money-maker. I, too, hate cold coffee with a passion and usually end up with such every time I bring a cup out to the shack. So, with his idea and my junk box of parts, I put together the Hot Mugger, destined to become the most popular piece of gear in the ham shack.

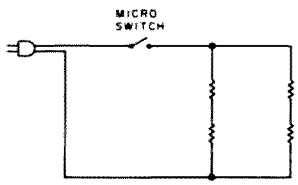

Fig. 1. Schematic.

I have used the Hot Mugger for several months now, and it works very well. But I have left a lot of room for improvement and would be interested to see other ideas for a coffee warmer. I am surprised that no one has written one up yet, as it is a very practical item for the ham shack. I hope this will set the wheels in motion and we will see many improvements and innovations.

The Hot Mugger does not require much in the way of parts. My junk box yielded all that were needed. There are four 550-Ohm, 15-Watt power resistors in series parallel, which gives 26 Watts of power dissipation. The 26 Watts does a good job of keeping a cup of coffee warm. I don't know how much lower you can go in power dissipation and still keep your cup warm, but you might try whatever you have on hand. I don't recommend exceeding 26 Watts, as this wattage will cause ¼ cup of coffee to become quite hot.

The cup should be a flat-bottomed one without any recess. I chose my cup before making the top for the coffee warmer so that I could cut the hole to the right size. The microswitch has a long actuator so that the cup will sit down on it and turn on the heating element (resistors). The base and housing were made out of printed circuit board, soldered and screwed together with an opening cut out of the top for the cup.

That's just about it except for painting. I used Rust-oleum® primer, which I don't recommend because it gave off a fishy smell for a long time afterward. Probably a good auto engine paint would be a better choice. A nameplate could be added so that your friends will know what it is.

As I type this, the Hot Mugger X1 is on the job keeping my coffee warm to the last drop. What is there left to say except, "Try it; you will like it." ■

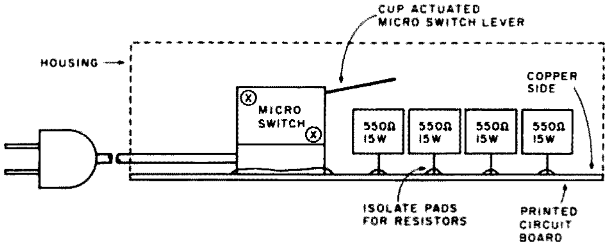

Fig. 2. Construction.

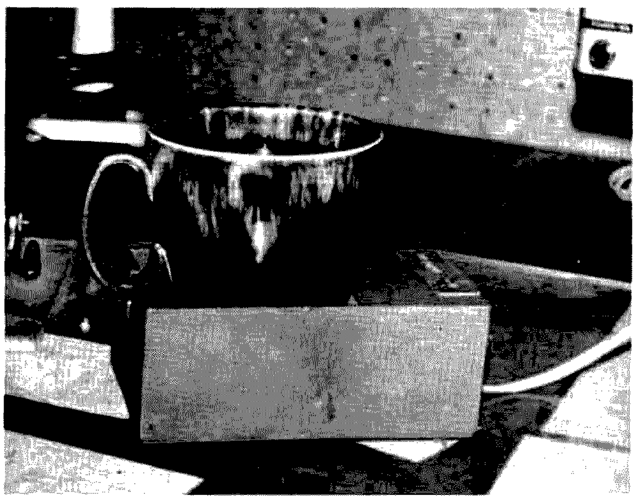

Side view of the finished Hot Mugger.

Build the Mini-Probe

—it's only logical

Decoding digital with a Polaroid™ pistol.

Here is an inexpensive logic probe that will determine all possible states of digital logic. It is built by point-to-point wiring on a piece of perforated board just wide enough to fit into a discarded Polaroid™ film-coating container and about 2½ inches long.

The Circuit

Referring to Fig. 1, the plus 5 V and ground connections are made to the circuit under test, and the probe is touched to the pin under test. If the pin is open, Q2 will conduct slightly because of the bias introduced by R1. This will cause the yellow LED to light at about half brightness. If the pin under test is ground, both Q1 and Q2 are off so neither LED will light. If the pin is high, the red LED will blink once because Q1 puts a high signal into the one-shot, and the yellow LED will light at full brightness because Q2 is turned on. If only the yellow LED were used, it would be difficult to differentiate between an open and an oscillating condition. This is where the one-shot goes to work. It gives a relatively long (.5 seconds or so) pulse anytime the probe goes high—even if for a very short duration. So if the probe contacts an oscillating pin, it will blink continuously.

Unless pulses of very high frequency are to be detected, there is nothing critical about the layout except for space economy so that the board can be slipped into the case.

So there, in a nutshell (plastic one), is a way to know what's happening inside that digital monster's mind.■

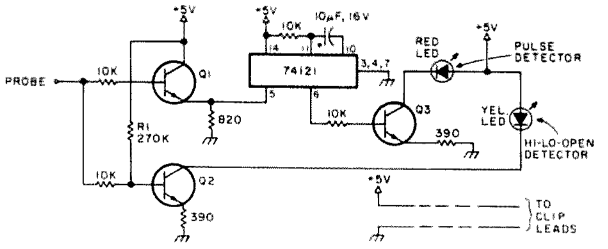

Fig. 1. Logic probe schematic diagram. Resistors ¼ Watt, 10%. Transistors ECG 123A or equivalent. LEDs as desired.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

interested in the same end . . . a better world, helped along a whole lot by amateur radio. Hamming can only provide these benefits to the world if it is fun, so let's all try to do what we can to make amateur radio fun . . . for everyone. I don't ask *you* to speak out against those who are lousing things up, whether by intention or stupidity—I just ask that you look into these things with an open mind and vote with your conscience.

ALSO AT ATLANTA

In addition to laying it on the line about amateur radio . . . and I expect the usual goon squad . . . I'll be talking about microcomputers. I'll be talking about them primarily in terms which may be of particular interest to you . . . how to make money in microcomputing. I'd talk about how to make money in amateur radio, but I don't know anyone who has figured it out yet. Perhaps those who are pushing for the Communicator Class license on 220 have the answer.

The opportunities in microcomputing are still as good as ever for making a bundle. The industry has grown some since I got involved. Sales in 1975 were about $5M. This went up to about $25M in 1976 . . . $100M in 1977 . . . and passed $300M in 1978. With Atari and Texas Instruments now hitting the market with microcomputers, 1979 is still an unknown quantity. Radio Shack has a very big lead and may just be able to hold it, what with about 10,000 of their stores selling the TRS-80.

I'll be talking about hardware which is needed and which can be marketed easily to make money. I'll be putting software into perspective. Mostly, I'll try to answer as many questions as I can. I may even talk a bit about the whole philosophy of making money . . . what the secrets of success are and how to achieve success if you want it. Most people have blundered into the trap of the good old American system . . . guaranteed to keep you poor for life and with no real hope of spectacular success. Is there anything to do about this? I think so . . . and the first step is to become aware of the system and how it can be beaten.

Will I be seeing you at Atlanta June 16-17th? I hope so. What about Dayton? I don't know . . . I skipped it last year, but haven't decided about this year yet. With two or three new magazines in various stages of getting started, Instant Software really getting going, and some other projects, I don't really have time to go most of the places where they want me, much less where they don't.

MEET ME IN ST. LOUIS

Yes, Wayne Green is coming to St. Louis . . . for the big hamfest on March 31st. I'll be talking about amateur radio . . . the good things and the bad. I'll be answering questions on just about anything. In addition to that, as at Atlanta, I'll be talking to microcomputer hobbyists about the many ways of making money in this new field. I'll try to give some perspective on what has happened and what I see as coming in both fields.

This will be my first trip to St. Louis, so I'm looking forward to it. I'll be getting in a day early, so I'll have a chance to get on the local radio and television stations and promote the hamfest.

If you're a Wayne Green fan, be sure to come to the show . . . at the new convention center. If you're anti-Green, it's even more important for you to come and make sure you are right in your assessment. Is it possible that you are more a part of the problem than a part of the solution? Find out at the St. Louis hamfest.

There will be a raft of exhibits and other talks . . . with manufacturers showing their latest ham gear and dealers doing their best to cut their own throats. They're lining up some fantastic speakers and forums (in addition to my talks), so you'll have a great time.

I'm looking forward to seeing you . . . please come.

THAT LONNNG ARRL PIECE

One of the problems is that I'm spread a lot thinner than I should be. Instant Software is demanding . . . as is *Kilobaud MICROCOMPUTING* . . . and with two or three more magazines in the planning stages, when do I sleep? This came to a head last month with my endless editorial about the League.

Normally, when I write an editorial, I sit down and write with smoke coming out of my typewriter. Then I find the heat abated a bit and write a second draft which is a bit less fiery. If I don't like the first two drafts, I try a third time. In December, *all* of the drafts of my editorial managed to reach print, end to end. I'm supposed to get a chance to review my editorial before it goes to the printer . . . but they skipped me last month. Rats.

Oh, I get annoyed at a lot of the crap I get from the League, but I'm not as upset about it as most people think. You'll perhaps get better perspective on this at St. Louis or Atlanta if you come and say hello and get into one of my talks.

ARTICLES NEEDED

Our increased use of color in *73* permits us to run some color photographs of interesting DXpeditions. The time was when we had to run all those pictures of gorgeous places in black and white. We're looking for colorful DXpedition pictures accompanied by interesting articles. An article will not only help pay some of the freight for the trip, but could also encourage others to help out a bit when they send for your QSL card. DXing is one of the most exciting aspects of amateur radio, so let's see more of the DXing fun in articles for *73*.

If I can get my new tower up, I'll be back in there scrapping with you for the rare ones. I'm a tough one to beat, so watch out! I racked up over 300 confirmed countries (all on 20m phone) in one year a while ago . . . and even managed 100 countries on 20m phone one weekend, just to prove to myself that I could do it. I didn't get much sleep.

It appears that we are up to here in antenna, keyer, and counter articles, but really in need of articles on transmitters, receivers, and transceivers. Surely someone out there has built a rig which will get thousands of hams hot to follow suit. Let's see more construction projects on ham gear.

It is my conviction that the tens of thousands of hams who have bought microcomputers should be using them in place of Teletype™ equipment. Let's have more articles on RTTY using microcomputers.

SLEP WRITES

A letter from Bill Slep (Slep Electronics) mentions that his ads have been selling stuff right and left. That's always nice to hear. Bill says that there has been a recent run on microwave equipment which hams are using to receive the TV satellites direct. I've been reading a lot about this recently and would like to encourage those who have been successful in getting something inexpensive together to do the job to write for us about it.

Why bother to get TV direct from a satellite? Well, right off the top there is the challenge. It isn't easy. Once you get set up, you'll be getting network program feeds. This means that you'll be able to get, for example, Johnny Carson before the salty language is bleeped out. You'll get a lot of programs which are not being broadcast in your area. You'll get the Home Box Office stuff . . . late movies.

I've been corresponding with Bob Cooper K6EDX/5, who publishes a magazine for the CATV field and is deeply into this direct satellite TV reception. I may be able to get him to either write an article for us or at least get him to get someone else to prepare such an article. Using commercial gear for the effort would run you into the thousands of dollars. Heck, just a receiver for 4 GHz costs thousands. Then they want you to buy a ten-foot dish and a special preamplifier. Some experimenters have been getting the stuff with a lot less expense and trouble. If you're one, write to me about it.

NEW COVER PRICE

The new cover price shouldn't come as much of a surprise to anyone. A big part of it is inflation, which has been running about 10% of late. It's been two years since there has been an increase in cover price. If inflation keeps up like it has (if you continue to let your congressman spend money on more and more government), the price increases will have to come more often. How'd you like to find a different price every month? Keep it up, Congress!

We see the inflation in many ways. Postage has gone up beyond belief . . . made even worse by the great big, thick, heavy issues of *73*. Paper costs have doubled in the last couple of years, and no end is in sight. Wages all around have been going up in step with inflation. Our advertising rates, once under $100 per page, are now over $1,500 for a page!

Obviously, the way to beat the cover price is to subscribe. I've been hinting gently at that for a long time. At $2.50 per issue, this comes to $30 per year. The subscription rate is $18 for one year and $36 for three years. That means you can get three years of *73* for just a little bit more than buying one year on the newsstand. Convinced? Remember when a life subscription was going for $37?

Of course, those early issues of *73* were much smaller (about one half the size of this page) and thinner. You're getting eight times as much material for about six times the price . . .

so it is a good deal. Fifty-seven feature articles in the November issue! That's more than all the other magazines combined, isn't it?

THE 10 GHZ SAGA

Chuck Martin WA1KPS started off going great guns (Gunns, that is) on 10 GHz with contacts with New Hampshire from Massachusetts, Vermont, Maine, and even the Granite State itself (106 miles between Pack Monadnock in southern New Hampshire and Mt. Washington, up north). From there on, the situation got more difficult.

A couple of tries from hills in Rhode Island didn't make it. The paths were even difficult on 220 MHz, so the failure on 10 GHz wasn't very surprising, even if it was disappointing.

Chuck got the two transceivers together and found little things to do which supposedly improved their action. He also borrowed a two-foot dish to perk up his end of the signal, just in case this would help. It might push a signal through some trees, but it wouldn't boost it over any mountains.

On November 19th, I braved icy winds gusting to over 80 mph up in the superstructure of a tower on the Pack, while Chuck relaxed up in the branches of a tree on a hill in Rhode Island. Well, he was perhaps only partly relaxed, considering that he was trying to hold on to the tree while he aimed the dish and tuned the transceiver . . . and gradually froze.

Perhaps it was worth it all. We did manage some short contacts as the two transceivers drifted in frequency about 16 MHz as they cooled down to the subarctic temperatures. The AFC system is pretty good, but definitely not equipped to handle that kind of drift. And tuning the little buggers is about like trying to tie an appendix with boxing gloves on. You have to turn the tuning knob about a thousandth of an inch to tune in a signal. This is interesting to do when you are being blown almost out of a tree or a tower by gusts of very cold wind . . . shivering . . . and your hands are turning blue as frostbite creeps up towards your armpits.

That makes five states on 10 GHz, with all contacts being over 50 miles. Anyone done better than that, or should we send it to the book of world records? Our laurels will not be crushed. Chuck has some ideas on pepping up the transceivers, and if we put the darned things outside so they can come to a steady temperature, we should avoid the drift miseries. The next stop obviously is Connecticut for state number six . . . if we can get organized before the snow hits.

Those little Microwave Associates Gunnplexers sure are good fun. They put out enough of a signal so that you should not have to have any additional antenna for a contact over any line-of-sight path. Our contact of over a hundred miles was plenty strong.

Sherry has been itching to get a hot air balloon ever since we went down to Florida and made the balloon cover for *73* a couple of years ago. If we get one, I understand that contacts from the balloon count for New Hampshire as long as the balloon is tethered. I wonder if a 5,000-foot kite string counts as a tether?

OCTOBER WINNER

Our readers have selected "Antenna Design: Something New!" as the best article in our October issue, so Harry A. Mills W4FD and Gene Brizendine W4ATE will be sharing our $100 Most Popular Article prize. Remember, your ballot is your Reader Service card.

DX

from page 14

from Greenland to South America out of our home base, Wright-Patterson AFB, on a two-week "worldwide" communications test of an experimental airborne satellite terminal. Among the crew of 25 men, we had four hams: Sandy Cole K1SC, Tom Walilko K8NOQ, Bob Beach W8LCZ, and Wayne Beeson K8WB.

After landing (on Ascension Island) on Saturday night, we immediately searched for the acting base commander, Captain Lord, and finally found him in a barracks card game. Captain Lord informed us that the required forms and the British Islands Administrator's signature needed to obtain our own ZD8 calls would not be available until Monday morning. Meanwhile, he authorized the use of your call, ZD8KG, for us as guest operators. He presumed your kind permission since you were not then on the island.

The authorization seemed adequate, as we had the word of the *Lord*, so we rushed over to barracks 14 and set up our FT-101E and 18-foot vertical antenna. Our first QSO took place just after midnight on September 17th with W7PFZ on 20 meter SSB.

We then proceeded to have the time of our lives working our first pileup from the fun (rare) end of the QSO. An awesome and enjoyable experience almost every DXer has dreamed of was coming true. All four of us took turns as noted in the enclosed log copy.

We worked 10, 15, and 20 meter CW and SSB. Conditions on 10 were great, so we used that band a lot in racking up 230 contacts from ZD8KG in about 36 hours.

On Monday, we filled out the required forms, got the necessary signatures, and finally received our own calls. Sandy got ZD8SC, Robert got ZD8RB, Wayne got ZD8WB, and I got ZD8TW. We still had some operating time left, so we returned to the rig and ran off 105 more contacts in the four hours before our plane took off for Brazil.

We totaled five continents, fifty countries, and 325 contacts, of which 101 were with stateside stations. We earned no awards but we had a terrific time.

During some hurried and confused packing, we yanked our antenna off the barracks roof in the middle of our last QSO with WB0TXV on ten meter SSB. A sudden end to our DXpedition. We all had a ball and can't wait to do it again. Our plane will return to Ascension Island in March, 1979, and again in the summer of 1980. We plan to bring multiple rigs next time and to use our newfound experience to cut through the pileups faster. Meanwhile, we left our aircraft number and 73 written with six-foot high rocks on the side of West Bay Hill near the barracks.

We requested everyone we worked to QSL direct to our home calls, but if you or your QSL manager, K4KBL, receive any cards for contacts we made, you can forward them to me. Again, thanks for the use of your call and we hope to see you on a future trip to the island.

Tom Walilko K8NOQ/ZD8TW
712 Sykes Circle
Wright-Patterson AFB OH 45433

BITS AND PIECES

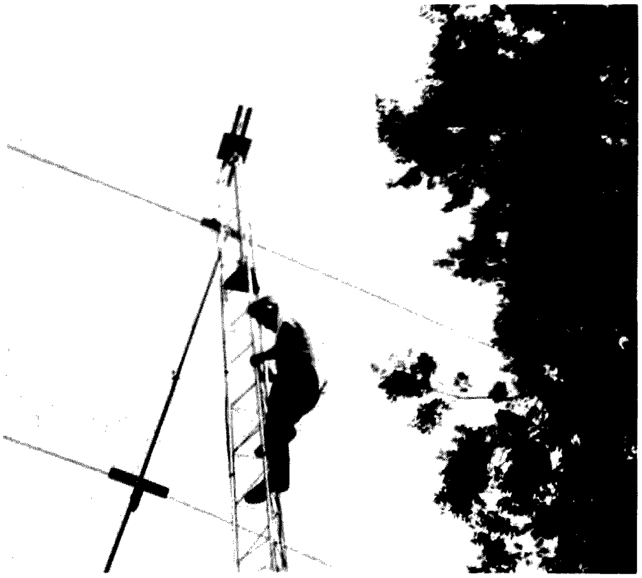
As of this writing, no documentation has reached the ARRL for the HZ1BS/8Z4 neutral zone operation. No documentation, no recognition.

If you still haven't worked KV4, there is really no excuse. KV4AA recently made his 38,000th QSO. Most are CW.

That W0DX who operated from Desecheo recently is Bob Denniston, former president of the ARRL. He runs the Smuggler's Cove Hotel on the north side of the island group.

4U1ITU in Geneva reports that they are receiving QSL requests for 4U1UN in NYC. The correct QSL route for 4U1UN is UN Staff Radio Club, United Nations, Box 20, NYC NY 10017. SASE, of course.

For those who are still confused by the FCC callsign allocations in areas outside the continental U.S., the following should be of some help. The



George Lindley WA5HKW erecting his home-brew three-element beam. George built it from plans in Bill Orr's Beam Antenna Handbook *for about one-third the cost of a commercial beam. He says it works great.*

digit is the key. Alaska stations sign AL7, KL7, NL7, and WL7. The rest are as follows.

Atlantic: 1—Navassa Island; 2—Virgin Islands; 3—Serrana Bank; 4—Puerto Rico. Prefixes are KP, NP, and WP.

Pacific: 1—Baker, Canton, Howland Islands; 2—Guam; 3—Johnston Island; 4—Midway Island; 5—Kingman Reef (K suffix); 5—Palmyra, Jarvis; 6—Hawaii; 7—Kure Island; 8—American Samoa; 9—Wake Island; Ø—Northern Mariana Islands. Prefixes are AH, KH, NH, and WH.

All the foreign nationals have been assigned YS9 prefixes in El Salvador. YS1WPE is now YS9YSS.

The operator at HFØPOL, the Polish base in the South Shetlands, left and the new crew contains no amateurs. QSLs have been printed, but there is a holdup in getting them filled out and mailed.

The ARRL is planning to take the FCC ten meter linear ban to court. As noted before, the innocent hams were the only ones to suffer from this ban. The manufacturers of illegal CB linears either went underground or switched to manufacturing high-powered "amateur transmitters." CBers just plug in their transceiver as a vfo. Passing laws to make it illegal for lawbreakers to break the law has never made much sense to us.

Those working toward WAZ should bear in mind that UAØYAE, heard often on 15 meter CW, is located in Tana Tuva, which is in Zone 23. In fact, any UAØY is in Zone 23.

Gary Yarus WBØMSZ puts out a directory of stateside QSL managers that contains over 1300 managers. This is almost a necessity for the serious DXer and at only $1.00, it's a great bargain. The address is: Gary Yarus, 921 N. Clay Avenue, St. Louis MO 63122, and the list is updated weekly.

UVØBB claims to be the first and only YL operator in Siberia.

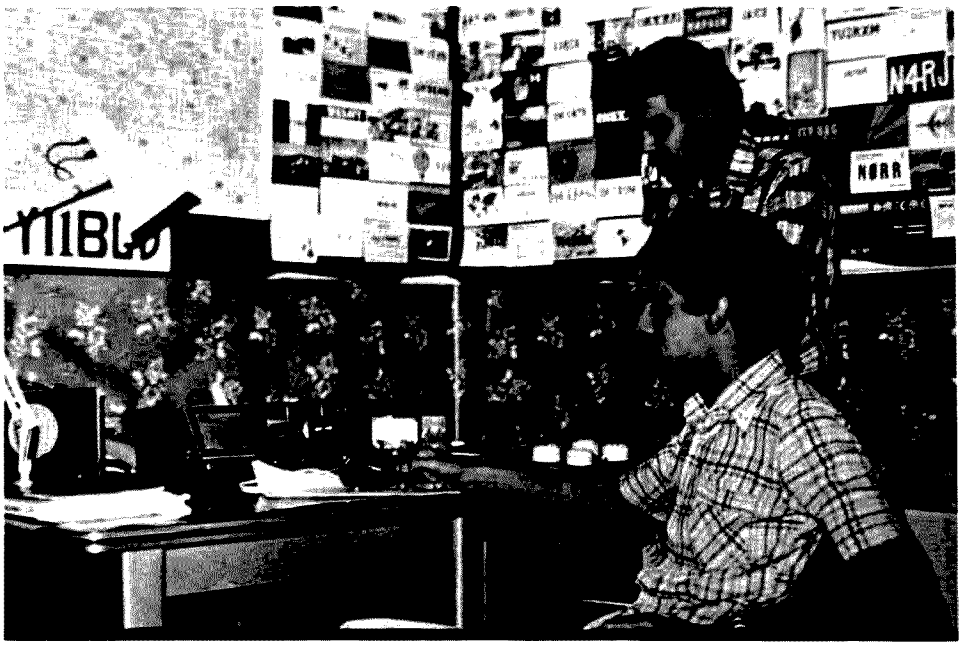
SV1IT is considering a possible Mt. Athos effort this summer. Nothing definite as yet, but if you run across him, you might ask for the latest word.

Amateur radio continues to experience rapid growth. Amateur licenses in the U.S. are expected to top 366,000 by early this year. There were some 28,000 new licenses issued during 1978. The total number of licensed amateurs in the U.S. has increased better than 100,000 since 1975. CB licenses, on the other hand, dropped below 100,000 per month last summer for the first time in several years. Look for several of the larger CB equipment manufacturers to jump into the amateur market.

QSL manager ON5TO notes that the true-blue 9U5CA has not been active since 1971. The one showing in '76-'77 was a pirate. Only 9U5CB, 9U5DS, and 9U5CR are legit at present.

The U.S. and Surinam, PZ, completed a reciprocal operating agreement on October 12. Amateurs of either country wishing to operate in the other country can do so upon application to the proper authorities. Information on this or any other reciprocal operating agreement can be obtained by sending an SASE to the ARRL. Reports indicate a reciprocal agreement with Spain is now in the works.

Ever wonder what the shack of a rare DX station looks like? Here's the operating position of the much-sought-after YI1BGD, the only station currently active in Iraq. Pictured are ops Majid (seated) and Saad, along with their Atlas transceiver. Can you spot your QSL on the wall? Thanks to Jack Winterbourne VE3ITO and the CARF News Service for the photo.



A note from K5OVC straightens out the Argentine-Antarctic callsign designations. LU-ZA, ZG, and ZM are South Orkneys. LU-ZY is South Sandwich. LU-ZC, ZI, ZO, SZ, and ZT are South Shetlands. Others are Antarctica.

Jim Henderson, who spent several months signing ZM7AH from the Tokelaus a few years back, wants to clean up any remaining need for ZM7AH cards and seal the logs permanently. Anyone still needing a card can reach Jim at 13490 Mt. Hood, Reno NV 89506.

The Mellish Reef operation, VK9ZR, managed some 16,000 contacts despite being plagued by generator problems that limited their output.

K4OD notes that he still has all logs from his previous overseas assignments and will be glad to confirm any contacts. Anyone needing a card from OA4DX ('68-'71), HP1XOD ('70-'71), PY1ZAL ('71-'73), EP2OD ('75-'77), or 9D5B ('76-'77) can reach Carl at PO Box 135, Front Royal VA 22630. SASE, of course.

EI8H is a legitimate station, but any EI8H/xx you hear is a definite phony. Pat has been getting loads of QSLs for these operations, but all are going into the trash and he requests that no more be sent.

ZD9GG can often be found on a list operation run by WA7ZTL on 14245 kHz around 1445Z. An Asahi newspaper recently took some aerial photos of Okino Torishima. The outlines of the barrier reef are quite distinct and the foundation of the never-built weather station can be seen in the center. Only two rocks are visible at high tide. One is five feet tall. It is difficult to imagine another operation taking place from here for quite some time.

The DX gathering on 14225 kHz after 1500Z is a great hunting ground. Check it out.

The first DXCC for 160 meter operation was issued on November 15, 1976. Since that time, twelve have been issued. #1 went to W1BB, of course, #2 to W1HT, #3 to W8LRL and KV4FZ (two were issued), #5 to K1PBW, #6 to W4BRB, #7 to W2QD, #8 to W2DEO, #9 to W4QCW, #10 to W4YWX, #11 to K4CIA, and #12 to W9NFC. The east coast pretty well has a lock on this award.

8J1JCI was a special station on from the Japanese Chamber of Commerce and Industry Centennial Exhibition.

QSL INFORMATION

In the November column, a typo snuck in directing QSLs for GU5CIA, GU4EON, and GU3YIZ to K5YY. This was an error and San says no more, please. The correct route is to N6MA, whose address is listed below.

3D6BA to WA4HNL
3YØBZ to VE7ZQ
3Y5DQ/3Y1VC to LA5NM
4079WARC to YU2DX
4NØD to YU2CQ
4N2EC to YU1JAS
7P8BH to WB9ZZK
8J3ITU to JH3DPB
9J2JN to WB2IZN
9K2FX to W4KA
GU5CIA to N6MA, 3800 J Street, Oxnard CA 93030
A7XAH to DJ9ZB
EX9A to Box 88, Moscow
H5RAC to WA4HNL
HH2DX to George Werner, 1045 Le Brun, Jacksonville FL 32205
HZ1AB to K8PYD

ZL3HI/C to N2CW, 207 West Fifth Street, Ship Bottom NJ 08008

Thanks to *The West Coast DX Bulletin*, the Long Island DX Association *Newsletter*, and *Worldradio Magazine* for much of the preceding information.

AMATEUR RADIO IN IRAQ

During a business trip to

Baghdad in September, 1978, I contacted Majid Abdulhamid, Chief Operator of the Radio Club of Baghdad, amateur radio station YI1BGD.

Majid gave me telephone directions to find the club premises, now located in the building of the General Directorate of Scientific Welfare in the Azamia district of Baghdad. This building also houses other scientific clubs.

I was met by Majid and another club operator, Saad Al Tai, both of whom accorded me a very courteous welcome.

On being informed of the general interest of North American amateurs in the situation of ham radio in Iraq, they explained their present status.

YI1BGD is the only legal ham station in Iraq at present. Majid is holder of the license, which is limited to the 20 meter band and 100-Watt input.

The club hopes to be permitted soon to operate on other bands and with higher power.

The present membership, besides Majid, consists of seven operators, including two YLs. Majid expects the club to grow as their activities become more widely known.

The whole operation was made possible through a radio course given by YU1NFV, who has since left Iraq.

The club station commenced operation on April 14, 1978, and has logged a respectable number of countries and QSOs since that time.

The present station is equipped with an Atlas 210 and a two-element quad which is operated manually. Recently, they received a donation from Japan of a Yaesu FT-101, which is awaiting clearance at customs pending the revised station license.

YI1BGD's operating schedule is Monday and Wednesday on 14210 MHz, and on Friday from 2000 UTC until 0100 UTC, their beam is directed at North America. At that time they have regular skeds with VO1CU (Gordon) and I2CBM (Bert) who act as control stations on their behalf. The Friday frequency is 14310 MHz.

When I enquired if they had any QSLs for VE3-land which I could carry back, they showed me the station log which indicated almost 100 percent QSL response from them. Those hams who have sent QSLs are quite certain to receive confirmation, but it will take time. It does not appear that the club takes long to respond, but the distance and conditions really slow things down.

The club has received some publicity in the Long Island DX Association bulletin, one of the British magazines, and locally in an Arabic publication.

My friends were kind enough to let me take a few pictures of them and their station (I hope the film survives the security checks on the return trip), and also gave me a small black and white print of four of the operators in the shack—Kamal, Majid, Mohammed, and Dhia.

Judging by the enthusiasm of these two men, the DX hounds will continue making regular contact with YI1BGD, but it is doubtful that there will be any other YI stations for some time. This information came to us courtesy of Jack Winterbourne VE3ITO, and was first published in the Burlington, Ontario ARC bulletin.—Ed.

ADMINISTRATION OF TELEGRAPHY EXAMINATIONS TO HANDICAPPED APPLICANTS FOR OPERATOR LICENSES IN THE AMATEUR RADIO SERVICE

Order extending time for filing comments and reply comments

AGENCY: Federal Communications Commission.

ACTION: Order Extending Time to File Comments.

SUMMARY: The FCC is inquiring into the administration of its telegraphy examinations to handicapped persons who apply for amateur radio licenses. The comment period ends November 30, 1978. Mr. Norman Kaplan has petitioned to extend the comment period. The comment period is being extended to encourage as wide a participation in the proceeding as possible.

DATES: The comment period is extended to March 30, 1979. The reply comment period is extended to April 30, 1979.

ADDRESSES: Send comments to: The Secretary, FCC, 1919 "M" Street NW., Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

Mr. Robert Cassler, Personal Radio Division, Safety and Special Radio Services Bureau, 202-634-6620.

SUPPLEMENTARY INFORMATION: See attached document.

Adopted: November 21, 1978.

Released: November 24, 1978.

In the matter of the administration of telegraphy examinations to handicapped applicants for operator licenses in the Amateur Radio Service, Gen Docket No. 78-250.[1]

1. On August 24, 1978, the Commission released a Notice of Inquiry into the administration of telegraphy examinations to handicapped applicants for operator licenses in the Amateur Radio Service. Comments were due no later than November 30, 1978. Reply comments were due no later than December 29, 1978.

2. A petition to extend the comment period to March 30, 1979 was submitted by Mr. Norman Kaplan of the Disabled American Veterans, North Miami Beach, Florida. Mr. Kaplan cites the need for as many handicapped persons to participate in the proceeding as possible. Because of the special nature of this proceeding, we agree with petitioner.

3. Accordingly, the Commission, by the Chief, Safety and Special Radio Services Bureau, pursuant to delegated authority granted to him by § 0.331 orders that the comment period and the reply comment period in General Docket No. 78-250 are extended to March 30, 1979, and April 30, 1979, respectively.

Carlos V. Roberts,
Chief, Safety and Special Radio Services Bureau.

OSCAR Orbits

Courtesy of AMSAT

FINDING OSCAR

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

New Products

from page 26

ing. The peak reading feature is a must for SSB transmitters. The MP1 also will display swr. Swr is measured directly, without having to use extra charts or graphs.

For ease of installation, the MP1 has a removable coupling unit which may be placed up to 4 feet from the meter.

The MP1 is portable. It contains the latest in low-power ICs and is powered by a 9-volt battery. For long-term non-portable operation, an optional ac adapter is available.

A low-battery-voltage indicator has been built into the wattmeter to indicate when the battery needs changing.

The MP1 will provide all the functions and features needed to maintain an efficient, well-operating HF amateur station.

For more information, please contact your local dealer or *Mirage Communication, PO Box 1393, Gilroy CA 95020; (408)-847-1857.* Reader Service number M75.

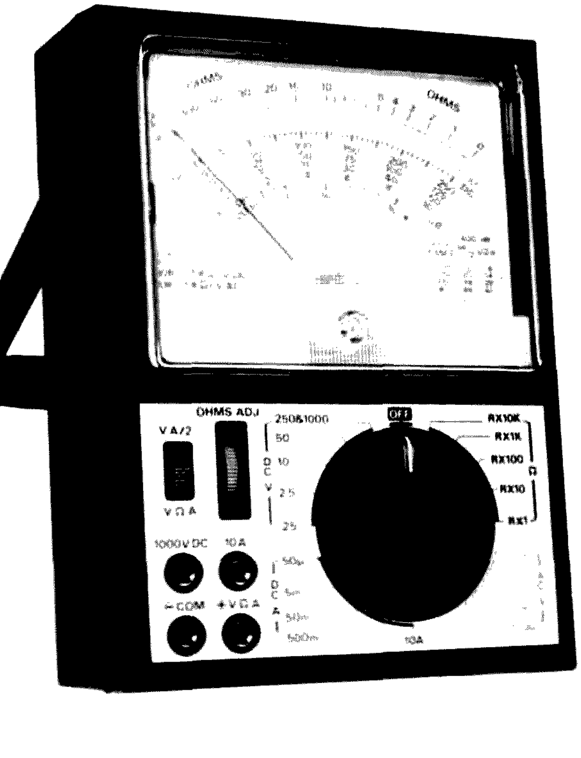
NEW MURA VOM MULTITESTER OFFERS DUAL-RANGE SENSITIVITY

Mura Corporation, manufacturer of home entertainment products, CB accessories, and electronic parts and components, has introduced a new precision VOM multitester with extremely high dual-range sensitivity.

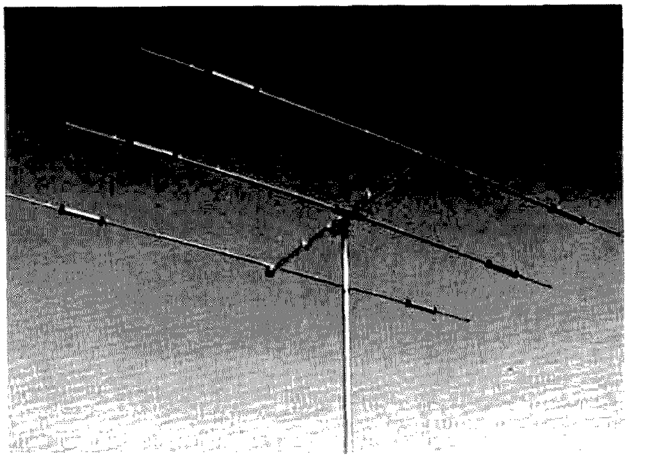
Designated Model 85-M, the new VOM multitester is ideal for use where measurements must not appreciably disturb a particular circuit being tested. It features high 50,000-Ohms/volt dc and 10,000-Ohms/volt ac sensitivities on one set of voltage ranges, and 25,000-Ohms/volt dc and 5,000-Ohms/volt ac on a second group of voltage ranges.

In conjunction with a power supply, the 85-M can be used to measure capacitance and inductance. Special circuitry has been included to protect the meter movement against accidental overload, and a mirror arc has been provided to help eliminate parallel error from readings. In addition, a convenient carrying handle, attached to the unit's high-impact casing, can be positioned for easy meter reading.

The new 85-M measures 6¾" x 5" x 2" and weighs 1 lb., 5 oz., with batteries. *Mura Corporation, 177 Cantiague Rock Road, Westbury NY 11590; (516)-935-3640.* Reader Service number M79.



The Mura Model 85-M VOM multitester.



Wilson's "System Three."

"SYSTEM THREE" BY WILSON

Wilson Electronics is proud to announce the latest in triband antennas for 10-15-20 meters. The "System Three" features lightweight design, heavy-duty materials, low swr across all three bands, a boom length of 14' x 4", wind survival of 100 mph, direct feed with 52-Ohm coax or with a balun, and a capability of 2000 Watts.

For more information on the "System Three," see your favorite dealer or contact *Wilson Electronics, Consumer Products Division, PO Box 19000, Las Vegas NV 89119.* Reader Service number W2.

YAESU'S FT-202R

"The Handie," a new miniaturized two meter handheld transceiver (Model FT-202R), has now been added to the Yaesu line of amateur radio equipment.

Measuring only 67 x 49 x 171 mm, the one-Watt-output, six-channel hand-held should please the most critical user with its excellent receiver performance and high-quality F3 transmitted signal.

The receiver is double-conversion, with a sensitivity measurement of 0.32 mV for 20-dB quieting. "The Handie" covers the entire two meter band and includes a flexible rubber ducky antenna and attractive carrying case. Crystals are supplied for three channels.

Other features include a combination "S"-meter and tuning meter, tone burst or subaudible squelch (optional), built-in speaker, and condenser microphone. Batteries required (not supplied) may be AA-size or nicads to provide 9.6 V dc (not to exceed 12 V dc).

For complete details on this new hand-held transceiver, see your Yaesu dealer or write to *Yaesu Electronics Corporation, PO Box 498, Paramount CA 90723.* Reader Service number Y1.

NEW CUSHCRAFT HF VERTICALS

Many hams are convinced that to work meaningful DX they need a couple of thousand Watts and a monster antenna array. While that undoubtedly helps, where is it written that the ham suffering a money or space cramp can't compete for his day in the DXCC sun?

Three new Cushcraft verticals, the ATV-3, ATV-4, and ATV-5, provide a commonsense solution to a commonplace problem. Specifically designed for the DXer, these antennas provide the low angle of radiation necessary for long-haul DX communicalton, along with the performance and quality long associated with the Cushcraft name. The ATV-3, ATV-4, and ATV-5 operate over the 10, 15, and 20 meter amateur bands, with the ATV-4 having built-in 40 meter coverage and the ATV-5 all set for complete 5-band operation.

All antennas feature a built-in PL-259 coax connector and stainless steel hardware for all electrical connections, and are matched to 50 Ohms and rated for a full 2000 Watts PEP. Factory-marked tubing and plain English instructions make assembly a snap.

Built to withstand the severest weather, the ATVs feature specially-designed high-Q traps employing large-diameter enameled copper wire and solid aluminum air-dielectric capacitors. The trap forms are manufactured from filament-wound fiberglass for minumurn dielectric loss and high structure strength. Durable 6063-T832 aluminum tubing with 0.058" (1.5 mm) wails used for the vertical radiator and the heavy-duty phenolic base insulator ensure long life and durability. All this adds up to an antenna line that comes through winter after winter a winner!

For more information and a

The new Mizuho SX-59 preselector from Gilfer.

full-color catalog highlighting the entire Cushcraft HF, VHF, and UHF antenna line, write to *Cushcraft, PO Box 4680, Manchester NH 03108.* Reader Service number C67.

GILFER INTRODUCES VERSATILE NEW RF PRESELECTOR/ PREAMPLIFIER WITH AUTOMATIC ANTENNA SWITCHING

If you are missing out on those weak DX signals because your receiver needs more sensitivity, here's a low-cost way to hype it up: Add the new Mizuho SX-59 preselector/preamp from Gilfer.

The SX-59 adds 20 dB of gain (3 or 4 S-units) with low noise. Tunable in 3 switched bands from 3 to 30 MHz, the unit is completely automatic in antenna switching—turn it on and it connects itself to the antenna, turn it off and the antenna is reconnected to the receiver. No manual bypass is needed.

Beautifully styled in a solidly-made beige-colored cabinet, the SX-59 has a built-in, switchable, 20-dB rf attenuator to cope with excessively strong signals, plus a range switch, rf gain control, tuning dial, LED "on" indicator, input and output coax (SO-239 and phono plug) antenna connectors, "remote" terminals, and a built-in power supply for 117 V ac.

It's easy to use. Just select the band and tweak the tuning dial for the maximum signal. You'll be surprised at what you're missing. And if you've an old single-conversion receiver, the SX-59 will also reduce those images by 4 or 5 S-units.

For complete information, write *Gilfer, Box 239, Park Ridge NJ 07656.* Reader Service number G6.

NEW STACO REGULATED 8-AMP POWER SUPPLY

A new regulated 8-Amp power supply from Staco, Incorporated, is built to operate amateur, commercial, and industrial transceivers, as well as other 12-volt dc equipment, from 120 volts ac.

The solid-state Staco RPS-8 is ideally suited for fixed output power. A unique current fold-back circuit and internal circuit breaker provide automatic dual overload and short-circuit protection. In the event of component failure, an automatic crowbar circuit protects equipment from high voltage. The RPS-8 features a surge current of 8.0 Amps, a continuous current of 6.0 Amps, and a full 13.8-volt dc output. Ventilated steel housing is clad with black and white vinyl to prevent scratches or mars. Each unit is complete with input power cord, switch, pilot light, and operating instructions. Output connections are easily made to the terminal board on the rear of the unit. The RPS-8 measures 3-5/8 inches x 5 inches x 8 inches, and is backed by a 90-day limited warranty.

For more information, contact *Staco, Incorporated, 301 Gaddis Boulevard, Dayton OH 45403.* Reader Service number S78.

Corrections

I would like to offer a reed relay update to my October, 1978, article ("Happiness Is A Smart Scanner"). This information is from Allied's catalogue #790 (page 180). The following relays may be used: stock no. 929-377 (mfr. type MRR1ADS), stock no. 850-1552 (mfr. type W107DIP-3), or stock no. 703-2012 (mfr. type AMP2012). Also, please note my new address.

John P. Skubick K8JS
791 106th Ave. N.
Naples FL 33940

I just had a letter from Harold Drennon WØFSC who was nice enough to point out an error that he found in my OSCAR turnstile antenna article in the November, 1977, issue, page 63, Fig. 3. In the 2m driving harness, the wording below coaxial line 2 read λ/RG-62A/U, but should be λ/4 RG-62A/U. This is the first notice of a problem I have had, and I am sorry it was not caught by me in the proofs. The original was okay, but the proofs are still my responsibility. I thoroughly checked the entire article again, while I was at it, and, sure enough, I found one of my own errors. Fig. 1 caption should be: "Vertical mast is 10' ± 5' . . ." Surely the builders caught that one or they got strange looks when they went shopping!

Dave Brown W9CGI
Noblesville IN

Eric Corbett WD8PYE and others have pointed out a few errors in the wiring diagram and description of the Novice keyer on page 44 of the March, 1978, *73 Magazine*. The following should be noted:

Fig. 1: IC1 pin 7 should be pin 4. C2 should be reversed (negative side grounded).
Fig. 2: D2 should be connected to R6 at the crossover point.
Table 1: With power applied but key not contacting, IC2 pin 5 should be low (not high as indicated).

Several hams have written with these difficulties, along with shorted diodes, etc. None of them has written to me a second time, so hopefully I have been able to explain enough to them to get their keyers working. If you are having any difficulties, and will describe any voltages differing from those in the article (with above corrections), I'll help you out.

Michael Windolph WØOGX
Chaska MN

Ham Help

I need information on how to update or increase the usability of a Hammarlund Super-Pro or BC-779 shortwave receiver. Any info would be appreciated.

Contests

from page 24

other ZS1 stations. All modes or combination of modes permitted. All bands or combination of bands permitted. Closing date for the award is July, 1979. No QSL cards are required. Send a copy of your log verified by 2 local amateurs. Fee: US $1 or 10 IRCs; ZS R1.00. Send applications to: The Award Manager, ZS1MO, PO Box 5100, Cape Town 8000, Republic of South Africa. A special indication is given for VHF contacts.

SECOND ANNUAL INTERNATIONAL SSTV CONTEST

The contest is sponsored by R. Brooks Kendall W1JKF and David Ingram K4TWJ.

CONTEST RULES:

Contest is held annually on the second full weekend of March from 1500 to 2200 GMT, Saturday and Sunday, 3/10/79 and 3/11/79. All amateur bands between 3.5 and 29.7 MHz may be used.

EXCHANGE:

Exchange of pictures should include callsigns, RST report, and contest number. FCC rules require verbal exchange of callsigns for U.S. stations. Do not include contact number.

CREDITS:

1 point for each station worked. A station may be worked once on each band for credit. 1 point for each state or province worked. 5 points for each country worked. 5 points for each continent worked. Total score is the sum of all the credits. Excessive discrepancies in the contest entry may cause disqualification. Entries become the property of the contest committee. The decisions of the contest committee are final.

ENTRIES:

Activity sheets should show station worked, state or province, country, and band (80, 40, 20, 15, 10). Summary sheets should show number of stations worked, number of states or provinces worked, number of countries worked, number of continents worked, and total score. Contest entries should be postmarked no later than 4/10/79. Top scorer will be awarded a certificate and a year's subscription to the magazine of his or her choice. Certificates will also be awarded to the top scorer for the most countries and most continents worked.

Send entries to either: R. Brooks Kendall W1JKF, 10 Stocker Street, Saugus MA 01906, or David Ingram K4TWJ, Eastwood Village, No. 1201 South, Rt. 11, Box 499, Birmingham AL 35210.

THE WORKED ALL WEST AUSTRALIAN SHIRES AWARD AND THE WORKED ALL WEST AUSTRALIAN POST CODES AWARD

To become eligible for these awards, it is necessary for overseas amateurs to work 40 shires and 50 post codes, respectively, with proof of the QSOs to be forwarded to the Contest Committee, c/o PO Box 6250, Hay Street, Perth 6000, Western Australia, along with 10 IRCs or equivalent for the initial award. Subsequent stickers will be issued free, although return postage will be appreciated.

A map of West Australia showing all shires is available from the above address for $2 Australian.

Ham Help

I am with the Canadians in Lahr, West Germany. My problem is this: The D.A.R.C. over here has a large number of QSL cards that belong to DA call holders. I am in the position of trying to locate amateurs and pass on the cards. I am *not* a QSL bureau, just a locating service.

At the time of writing, I find myself with over 5000 cards, DA1, DA2, DA4, and DJ (foreign civilians), all of which the D.A.R.C. is unable to locate. So, for some time now, I have been trying to locate same, with little or no luck. Most of the U.S. Army DA call holders are moving around all the time, including going back home, so a lot of amateurs are without their QSL cards. If you are missing some QSLs, let me know.

In the October, 1978, issue of *73 Magazine*, in Ham Help, I asked for a simple modification for the popular Kenwood TR-7400A in order to receive the Civil Air Patrol frequency of 148.15 MHz. A reader (Gerald Gray WAØIKA of Topeka) came up with the mod, and I would like to pass it along for use by other 7400 owners. The only components needed are a small switch and a diode. Connect as follows: With the top cover of the radio removed, install an SPST switch with one lug grounded to the cover. Locate the switch directly behind the CT1 terminal. Connect the cathode of a 1N914 diode to the other switch lug. Add a 2" piece of wire to the anode, and slip shrink tubing over switch lug, diode, and wire. Strip the other end of the wire approximately ½" and wrap it around terminal CT1 on PD board X50 1380 10 (refer to Kenwood manual); no solder is required. Install the cover. Label the switch "Receive, + 600." With this switch in the closed position, I can receive the CAP frequency of 148.15 by setting the display dial of my transceiver on 147.550, and, with the TX offset of +600, I can simplex on the frequency. No change is required to transmit on this frequency, and just turn the switch off to receive the frequency displayed. My thanks to Gerald and *73 Magazine*.

George E. Taylor WA4GUW
Muscle Shoals AL

I need to get in touch with other amateurs, faculty members on the college or university level, who teach biomedical electronics and instrumentation. I'm on the faculty of the University of Texas School of Allied Health Science in Houston.

MDs interested in the subject are also very welcome. However, I am seeking resources on at least the post-graduate level in Health Related Science. In addition, those interested should be "teaching oriented."

I have an old Hallicrafters S-85 receiver and would like to modify and utilize it for DX work as the receiver is extremely sensitive. I am in need of a schematic and operator's manual. Thanks.

Charles Bott DL-579/WW
PSC Box 56
APO NY 09123

I am in need of an operations manual and schematic for a Dumont Labs type 350-R oscilloscope. I will pay for copies, or whatever arrangement we can come up with.

James G. Brown
15 New Ocean St.
Lynn MA 01902

I need a manual or complete schematic for a Motorola 41 V dispatcher (high band, 110/12 volts). It is needed for a club project.

Chuck Bennett WB8GQW
17060 Paver-Barnes Rd.

Route 31. Admission is $2.50 per person. There is plenty of space, with over 200 sellers' tables, and displays from major manufacturers. There will be seminars and door prizes.

VERO BEACH FL
MAR 17-18

The Treasure Coast Hamfest will be held on March 17-18, 1979, at the Vero Beach Community Center, Vero Beach, Florida. Activities will include prizes, drawings, and a QCWA luncheon. Admission is $3.00 per family. Talk-in on 146.13/.73, 146.52/.52, and 222.34/223.94. For information, write PO Box 3088, Vero Beach FL 32960.

JEFFERSON WI
MAR 18

The Tri County ARC Hamfest will be held on March 18, 1979, at the Jefferson County Fair Grounds, Jefferson, Wisconsin. Advance tickets are $1.50. Reserved 6-foot tables are $2.00 in advance, while 6-foot space is $1.00. For information, send an SASE to Glenn Eisenbrandt WA9VYL, 711 East Street, Fort Atkinson WI 53538.

LAWTON OK
MAR 23-25

The Lawton Fort Sill Amateur Radio Club, Inc., will hold its 33rd annual hamfest at the Montego Bay Motel Complex at Lawton, Oklahoma, the weekend of March 23-25, 1979. There will be the usual large flea market, ARRL officials, technical programs, QCWA breakfast, and activities for the ladies.

EAST RUTHERFORD NJ
MAR 24

The Knight Raiders VHF Club, Inc., will hold its world-famous flea market at St. Joseph's Church, East Rutherford, New Jersey, on Saturday, March 24, 1979. Doors open at 10:00 am. There will be free admission and free parking. Refreshments will be available. Flea market tables are available for: $5.00/full table or $3.00/half table, in advance; $6.00/full table or $3.50/half table, at the door. Talk-in on 146.52 and 144.65/145.25. For further information, call Bob Kovaleski at (201)-473-7113 or Jack Mandelberger at (201)-857-0016 (evenings only). Send reservations to: R. Wetzel, 419 Union Ave., Rutherford NJ 07070, and make checks payable to: Knight Raiders VHF Club, Inc.

WAUKEGAN IL
MAR 25

The Libertyville and Munde-

lein Amateur Radio Society will hold its second annual Lamarsfest on Sunday, March 25, 1979, at the J. M. Club, 708 Greenwood Ave., Waukegan, Illinois. Doors will open at 7:00 am. There will be plenty of free parking, door prizes, and a large indoor flea market for radio and electronic items. Tables will be available at $4.00 each. Advance tickets are $1.50; $2.00 at the gate, with children under 10 free. Hot lunch will be available and there will be plenty of commercial exhibits and demonstrations. Talk-in on 146.94. For further information, write LAMARS (include SASE, please) at 1226 Deer Trail Lane, Libertyville IL 60048, or call (312)-367-1599.

MUSKEGON MI
MAR 30-31

The Muskegon Area Amateur Radio Council is sponsoring the ARRL Great Lakes Division Convention and Hamfest at the Muskegon Community College in Muskegon, Michigan, on March 30-31, 1979. This event will feature manufacturers' exhibits, technical forums, and a large swap shop. Ample parking and dining facilities are available. Friday evening at the Muskegon Ramada Inn, there will be a "Ham Hospitality" with libation courtesy of the MAARC and a Wouf Hong initiation. For additional information, contact MAARC, PO Box 691, Muskegon MI 49443, or H. Riekels WA8GVK, (616)-722-1378/9.

COLUMBUS GA
MAR 31-APR1

The Columbus Amateur Radio Club will hold first annual hamfest from March 31-April 1, 1979, at the Columbus Municipal Auditorium, US 27 & 280, Columbus, Georgia. Donation is $1.00 at the door. There will be plenty of free parking and overnight free RV space. Exhibitors and flea market will be inside, with a free flea market outside. Talk-in on 28/88. For advance registration and details, write Bob Glasgow N4BGN, 1503 Layard Drive, Columbus GA 31907; (404)-561-7746.

WILLIAMSPORT PA
APR 29

The West Branch Amateur Radio Association will hold its 15th annual Penn Central Hamfest on Sunday, April 29, 1979, from 11:00 am to 5:00 pm at the Woodward Township Fire Hall, Rt. 220 south from Williamsport. For more information, write Richard Sheasley K3QDA, RD 1, Box 454, Linden PA 17744, or call Tony at (717)-322-6017.

NEENAH WI
MAY 5

The 3-F Amateur Radio Club will hold its annual swapfest on Saturday, May 5, 1979, from 8:00 am to 3:00 pm, at the Neenah Labor Temple, 157 S. Green Bay Road, Neenah, Wisconsin, just off Highway 41 at the Highway 114 or 150 exit. Facilities include a large parking area and a large indoor swap area with a free auction at the end of the day. Food and beverage will be available. Advance admission for tickets and tables is $1.50; $2.00 at the door. Talk-in on 52/52. For reservations, write to Mark Michel W9OP, 339 Naymut Street, Menasha WI 54952.

SALINE MI
MAY 13

The ARROW Repeater Association will hold its annual Swap and Shop on Sunday, May 13, 1979, at the Saline, Michigan, fairgrounds. Admission, including parking on the fairgrounds, is $1.50 in advance and $2.00 at the door. There will be food, prizes, and a covered area for trunk sales, as well as indoor tables. Because of Mother's Day, wives will be given free admission. Talk-in on 146.37/97, 223.18/224.78, and 448.5/443.5 MHz. For additional details, write ARROW, PO Box 1572, Ann Arbor MI 48106, or call George Raub AD8X at (313)-485-3562.

Ham Help

My divorce broke me. (Among other things, I lost my TR-4.) Does anyone have any ham gear to spare? A homebrew 40m CW transceiver would do. Thank you.

Lin Hamilton WB6PAV
14100 Chadron Avenue
#130
Hawthorne CA 90250

Hopefully, your Ham Help column can help me find the information I want. I would like to get in touch with anyone who is still using an old Galaxy V transceiver on the air today and find out what their opinions are of it.

Rick Todd KA8AKL/N
14470 Basslake Road
Newbury OH 44065

I would very much appreciate help from anyone in finding a circuit diagram of the McMurdo Silver Masterpiece VI.

Reg Trickey G3DRB
31 Pensby Ave.
Chester, England

I would like to obtain a copy of the original owner's manual for a Viking "Courier" linear amplifier.

John I. Nelson AA7W
19025 73rd Avenue N.E.
Bothell WA 98011

I need a schematic for a Johnson Model 122 vfo. Any help in obtaining this will be greatly appreciated.

Bill Richmond WD4CPQ

NEVER SAY DIE

editorial by Wayne Green

WHAT WENT WRONG AT THE ARRL?

Yes, I can hear the sighs of resignation from ARRL devotees . . . won't Wayne *ever* stop attacking the ARRL? . . . and why is Wayne trying to kill off the *only* national organization representing amateur radio? What utter nonsense!

The ARRL could and should be an organization which is run for the benefit of radio amateurs everywhere, and one to which all of us should be able to point with pride. The fact is that it is a sorry mismanaged shambles. It is managing to lose money despite the highest membership in history, and despite the most advertising in history in its magazine. To be able to come up with a disastrous deficit in the face of such monumental prosperity indicates either extremely bad management or else a very heavy hand in the till. We're talking about *millions* of dollars.

If the board of directors had any real power to manage the League, one could lay the blame for the problems at their door. One or two fast meetings a year which are almost totally controlled by the headquarters "Mafia" hardly constitute much power to control. I don't think we can really blame the directors, other than to perhaps let them know that we think they should have recognized the problems and gotten together to really do something about them, even if it meant the immediate firing of Baldwin and his cohorts.

THE REAL PROBLEM

The seeds of the disaster presently befalling the League go back many years. The odd situation is that it is the success of the League in drawing in newcomers that has led to things coming apart.

Sometime in the early days of the League, it was decided that everything possible should be done to prevent any other organization ever getting a chance to get started. This would perpetuate a competition-free situation and allow the ARRL to be a dictator in the field. In order to get anything serious going in opposition to the League, it was believed that another group would have to have a publication to use as a medium for communication with its members and for drawing in new members, much as *QST* has been used by the League all these years. To discourage this possibility, the advertising rates of *QST* were set at such a low rate that it was thought no sane persons would try to buck the establishment (ARRL) by competing with them.

Not too long ago, I sat down with a list of the advertising rates of all of the magazines in the country (SRDS) and compared their advertising rates with those of *QST*. I found that few of them had ad rates less than three times those of *QST* for the same approximate number of readers, and most were four or more times the *QST* rates.

If this is true, how is it possible? And how come there *are* some competing ham magazines . . . one of which obviously is doing rather well? The key to the legerdemain by which the ARRL was able to keep their ad rates so low was in their special second-class postage rates as a nonprofit organization. These rates are a tiny fraction of the rates paid by any regular magazine publisher. This means a saving of thousands of dollars a month, paid for by the U.S. government instead of *QST*, and substituted for the income which would normally be expected from advertising.

But, then, how can *73* compete against the low advertising rates and succeed in spite of the ARRL scheme? The secret to this, as anyone who has visited the *73* HQ can attest, is in efficient management. *73* is run from an extremely low-cost part of the country, from a very low-cost building, without the fantastic executive salaries of the ARRL, and almost all functions of the publication except printing are done in house.

No one knows for sure how much the head men at ARRL HQ make except the directors. You won't find it in the annual reports, nor will you even find any listed expenses which will give you a true hint of the salaries. I've been told that some go as high as $100,000 per year, but I doubt if they really are much over $75,000. At one time, the two top people at the League were making more than the entire staff of *73*.

THE CURE

A few years ago, before I got so involved with computers, the smartest thing the ARRL directors could have done would have been to make a deal whereby *73* and *QST* would amalgamate and I would manage the League. I guarantee you the organization would be in the black, our future would have been a lot more secure at WARC, we would have a lot more satellites up and running, and we would still have most of our ham satellite frequencies. The League needs a strong entrepreneurial type of person, not obfuscating bureaucrats who have come up through the ranks by never offending anyone.

LETTERS

BLACK HAMS

The letter by Jack Chancellor W9SON in the November, 1978, issue raised some interesting questions. How many black Americans are hams? How are black hams responded to during QSOs and in amateur radio activities?

I'm a black American ham, licensed since 1954, and in spite of extensive travel in 27 states in the course of my professional activities, I've never met a black ham. I may have worked other black hams on the air, but I've never had a QSO where the other op identified himself as black. (Research shows that recognition of the race/creed/color of a speaker by voice alone is next to impossible.)

Reactions to me by hams here in my hometown who have learned that I'm black have been 100% positive, though I don't doubt that some anxiety has been aroused. One instance bears relating: My first affair with 2 meter FM was quite a mix-up until a local ham straightened me out on the 600-kHz difference between transmit and receive frequencies through the repeater. After many, many QSOs, he agreed to stop by my place to pick up some gear I was donating to the local amateur radio club. Naturally he discovered I was black. Then he had to withdraw an earlier invitation to my wife and I to be his guests at his club (which is a block from my QTH, by the way) because his club does not admit blacks, either as members or guests.

This same local radio club had several blacks enrolled in its Novice code/theory classes. Another local radio club urged my participation in a practice emergency net on 2 meter FM. Any number of individual local hams and I have chewed the fat at length, on and off the air, about every topic under the sun. Never has the question of my race arisen (except in discussions of racial problems in the United States).

Although I've never personally experienced racial prejudice as a ham, I'm confident prejudiced hams do exist who practice their prejudices with varying degrees of directness—from "pulling the plug" the instant they discover the other op is black to adding to their CQ calls "no lids, no kids, no blacks."

I'm equally confident that, as W9SON asserts, there are blacks who believe that amateur radio is not open to them. This is not true objectively, but most blacks perceive reality in terms of the history of the black man in America—slavery, discrimination, and prejudice. Why, they say, should I believe the amateur radio fraternity to be any different from others which are predominantly white and known to be discriminatory.

I don't quite agree with W9SON's suggestion that perhaps ham radio should mount a campaign to dispel such beliefs among potential black hams.

I do believe, however, that our fraternity can, through each of us as individuals, attract the support and participation of many blacks in America if we would act toward them, on and off the air, as we would have them act toward us.

Carlton D. Trotman W3BRX
York PA

SELF-CREATED DOOM

I am writing this letter not so much as a letter to the Editor, but as a message to all hams!

I receive all of the ham magazines. I occasionally read your editorials. I am not too outspoken. However, the more I read about WARC, I decided I would come forth as a loud minority, and not as a silent majority.

I am a black ham, but I have some ground to stand on: nine years in HF communications for the United States Army Signal Corps, in fixed station point to point, Acan Starcom Stratcom and DCA, along with one year at Ohio Bell, and four years at the R. L. Drake Company. My present position (for the past six years) is as a two-way and microwave technician at the Dayton Power and Light Company. I presently hold a First Class Radio Phone and Extra Class license. In addition, I am the past General Chairman for the Dayton Hamvention, and also past Technical Chairman for DARA.

So you see, communications is my business! I cannot sit back and fool myself about what is about to take place. What we should think about is that if the ship sinks, we all go down. Even that guy who claims there's nothing to it. Noah tried to tell people that God was going to destroy the world. They laughed at him until one day they woke up and saw the water rushing upon them.

The hams will sit down and discover there aren't any ham bands anymore! Someone will say, "What in the world has happened?"

I am not going to sit by and let ham radio die because of the lack of exposure in countries that are still using the drum for communications. I want you to know that I am beginning to see the storm clouds. I guess I am a militant ham operator. For what it's worth, this one time I am joining the loud minority.

Another important concern is that, while I don't know about other towns, Dayton has a great deal of deliberate man-made interference. It's outrageous! If the FCC cracks down on ham operators, it's the hams' fault. The ham is destroying himself and the services available to us.

For instance, a guy will walk right out of his office past a phone, enter his car, and use the autopatch to find out whether his wife needs anything from the store!

Ham operators will create their own doom!

Need I say more?

Wallace M. Wright, Jr. AD8N
Dayton OH

HOT TYPEWRITER

I read your editorial entitled "WARC Doom and Gloom" in the December, 1978, issue of *73* and boy, did it strike a nerve! I am one of those operators who still uses his old Novice 75-Watt rig, but many OMs and YLs I QSO with on the air are using new equipment into which they have sunk a considerable hunk of change. Imagine telling these ops that their bankroll has sprouted wings, their beautiful riceboxes are now illegal, and they can resort to the landline for DX!

You could have used half the editorial space for printing the names, addresses, and phone numbers of members of the ITU, the U.S. Congress, the FCC, the ARRL, and anybody else who can help prevent the WARC from becoming a disaster for hams.

Don't worry, the powers-that-be would get mail, radiograms, phone patch calls, personal visits, etc., by amateurs concerned about the future of ham radio.

I wish you would have limited your visions of gloom. Phrases like "if we lose everything" are unsettling breaches of the peace. You are going to get a lot of people riled up with that hot typewriter of yours.

Regarding the ARRL: I quit when incentive licensing came out. Why should we subsidize someone who is taking away our bands? If the ARRL helps us out at WARC, great. If they don't, then how can they justify their existence? We need some people in the ARRL with some common sense, not foolish vindictive mossbacks—without mentioning any names.

I have one last question for you, Wayne, How is *anybody* going to keep millions of low-power CB radios and hundreds of thousands of ham rigs out of reach of curious individuals who want to satisfy that age-old need to communicate?

Bob Wilk WA0OTV
Kansas City MO

A HELL OF A CONTEST

You may not publish this, but this is my opinion of contests: They can go straight to hell. I am referring to the contests of December 9, 1978. Never in my life have I heard a ruder bunch of people on the air. I couldn't carry on a QSO of any kind without some damn fool breaking in and hollering "CQ Contest, 5 by 9 in Oregon, QSL?"

Whoever authorizes this bull ought to be horsewhipped with a linear. If the ARRL is the authorizing source, then the authorizing person needs his or her you-know-what kicked. This isn't my opinion alone, but just one of a whole lot of people who feel the same way. If I want a signal report, I will ask for it during a QSO. While I am in a QSO, I don't want to hear some jerk hollering "CQ Contest."

If people are going to be rude, then they should go back to CB radio where being rude is part of it. Amateur radio doesn't need it, nor do the vast majority of hams I know.

Dale Dishon WD5JRF
Palestine TX

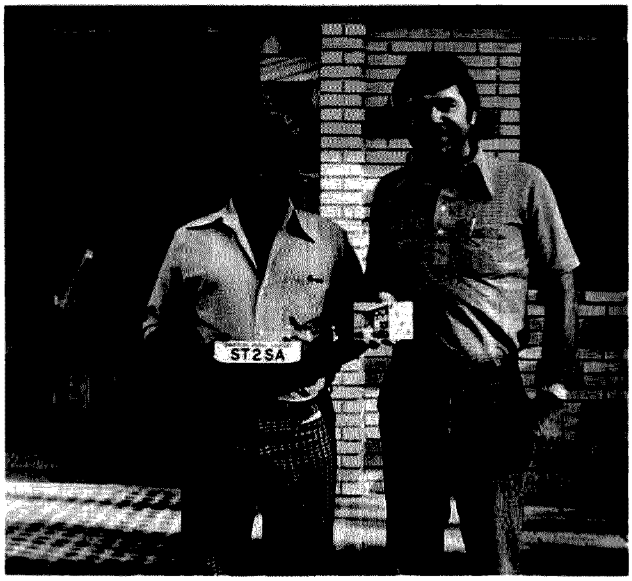
POLAROID POWER

I came across an idea and thought you might want to know, if you don't already.

My father bought a Polaroid SX-70 camera recently and, as you know, it takes the cartridge-type film with the battery built right in the film pack. Every time you put a new film cartridge in the camera, you are putting in a new battery.

I took one of those apart tonight just out of curiosity and discovered that it was a flat paper pack with chemicals sealed inside. I thought that the

Continued on page 203



ST2SA and K5YY.

son K5YY racked up some 6,000 QSOs from several of the rarer African spots including ST2SA, ST0YY, 3B8YY, FH8, D68AD, and 5H1.

San's main objective was to activate some areas that had seen little or no CW action and to concentrate on the west coast areas of the United States that generally have poor propagation into the East African and Indian Ocean areas.

The results were 6,000 QSOs, of which 20% were on CW and 68% were with stateside stations. Twenty percent of the stateside contacts were with W6 and W7 stations, including 50% of the contacts made from FH8, where he was really concentrating on the west coast. Although limited to only short stays due to travel accommodations, San managed 800 QSOs from ST0YY in six hours and some 400 QSOs each from FH8 and 3B8 in only four hours of operation at each stop.

An acute fuel shortage in Sudan cancelled all flights for over a week, but San was able to catch a charter flight to South Sudan which had to return to Khartoum the next day. Otherwise, he would have been stranded and the last half of the trip, including D68, FH8, and 3B8, would have been jeopardized. Luckily, it was a weekend and conditions were good.

Travel plans and itinerary had to be constantly changed and updated because of widespread airline flight cancellations. Getting a seat on another flight was nearly impossible and several tickets had to be repurchased because most places did not exchange tickets when flights were cancelled.

San's baggage was lost at FR7 and the last part of the trip was made with just bare toilet articles and only two pairs of shorts and socks. He wore the same clothes for twelve straight days. All his equipment was also lost.

Due to a food shortage at ST and D68, San lost twelve pounds. Upon returning home, he developed a subacute case of malaria, despite having taken all the proper anti-malaria drugs before departing. It was six weeks before he felt back to normal again.

On the bright side, the temperature in Sudan was only 105 to 110 degrees while he was there instead of the 130+ degrees just prior to his visit. Conditions at the Indian Ocean stops—3B8, D68, and FH8—were pleasant but very boring without ham radio.

San reports that the few good experiences included meeting some very nice people on the trip. Sid ST2SA and Alex 3B8DA were especially nice. 3B8CJ was not a big DXer, but he went out of his way to help San obtain the 3B8YY call instead of the 3B8Z calls which are usually issued to foreigners.

FH8OM and FH8YL were extremely nice and San reports that Beatrice FH8YL is very beautiful. Reiner FH8OM is the Honda and Yaesu dealer for the Comoro/Mayotte/Reunion area. Reiner was kind enough to take a day off and fly San from Mayotte to Kenya.

Robin D68AD is chief engineer of the Comoro Cable and Wireless and San says one of the nicest people he has ever met. San stayed with Robin while on Comoro and used his equipment. The FT-101E which had been donated by the Northern California DX Foundation had been left with FH8CY on Mayotte. All the other equipment was lost with his luggage.

San gives special thanks to Jack W2LZX for meeting him at the airport in New York both going and coming, and to Tony WA2EAN, who had finally managed to locate San's baggage which had been on Reunion all the time.

More special thanks to those who contributed equipment and money to the operation. The Northern California DX Foundation, whose contributions of an FT-101E and finances allowed San to go more places and stay longer, also provided the QSL cards. As mentioned before, the FT-101E was left with FH8CY in Mayotte to provide more operating time from that country. MFJ donated a keyer and antenna tuner and Butternut Electronics and Mor-Gain Electronics provided antennas.

Tired once more of the soft life and not one to rest on his laurels, San is planning to head out to more unconquered worlds later this summer or fall. Working once again with the Northern California DX Foundation, San has plans for three spots, all on the top ten needed list. Keep an eye on the DX bulletins for later information.

OBTAINING A VP2V LICENSE

We recently received a letter from Mr. A. M. Swain, Telecommunications Officer of the British Virgin Islands, explaining the procedure involved in obtaining a VP2V license. We are reprinting it here in case anyone might be interested in a vacation/DXpedition this summer.

1. You must possess a current U.S. amateur radio license of General Class or higher.
2. The annual license fee is $15.00, and each license or renewal expires on January 31st in the year following the one in which it was taken out.
3. Provided that a license is first granted after the first day of August, the fee shall be fifty percent of the fee specified.
4. Send a certified copy of your current license, along with a Postal Money Order made payable to the "Accountant General." No personal checks can be accepted. You must also include a 5¢ stamp to cover "stamp duty." Mail to: Ministry Of Telecommunications, Works

K5YY with FH8OM on the left and D68AD on the right.

Microcomputer Interfacing

Christopher A. Titus
David G. Larsen
Peter R. Rony
Jonathan A. Titus

Microcomputers are amazing devices, with an endless variety of useful applications. If you've followed the I/O articles in 73, you are probably aware that the key to using microcomputers for practical purposes is the ability to interface them to the real world. Computers are completely useless unless they can be made to accept inputs from devices like keyboards, temperature sensors, or receivers and generate output to devices such as video terminals, fire alarms, or Model 15s.

When we decided that a monthly column was needed to explore the important topic of microcomputer interfacing, we were pleased to learn that such a column was already being written by The Blacksburg Group, authors of the well-known Bugbook Series™. In recent years, the column has appeared in the scientific publication American Laboratory, where it's been quite popular.

While this column will not deal specifically with amateur radio, the interfacing techniques discussed here will benefit anyone who wants to get more out of his micro, including hams.—Jeff DeTray WB8BTH, Assistant Publisher.

INTERFACING DIGITAL-TO-ANALOG CONVERTERS

An *analog-to-digital converter* is an electronic device that converts analog signals to digital signals. Typical commercial converters are based upon the principles of successive approximation, dual-slope integration, staircase-ramp conversion, or voltage-to-frequency conversion.[1] The most common use for an ADC is to convert the output from an analog transducer or analog instrument into digital form suitable for direct observation on a digital display or as input into a computer. All digital panel meters and digital multimeters contain built-in analog-to-digital converters. Modern ADCs provide standard TTL outputs which may be coded in binary, binary-coded decimal (BCD), or perhaps other less frequently used codes.

To illustrate how you would interface an ADC to an 8080-based microcomputer, consider the generalized 10-bit ADC module shown in Fig. 1. In addition to the 10-bit output and analog input pins, our module also contains a START input and a DONE/BUSY output, whose functions will be discussed later. It is not possible to simultaneously transfer all ten bits from the ADC into an 8-bit microcomputer. For the 10-bit converter, the data transfer is accomplished by placing bits D0 through D7 (the ADC's eight least significant bits) in the first input byte and the remaining two bits, D8 and D9 (the ADC's most significant bits), in the second byte.

To gate data onto the data bus and into the 8080, 8212 eight-bit three-state buffer chips are used between the ADC's outputs and the 8080's data bus. A gating scheme is required so that the three-state buffers are enabled only during the time when the 8080 requests data. In the case of the 8212 buffer, the required gate is incorporated within the integrated circuit chip, so all that you must supply is a negative IN control signal and positive 065 and 066 decoded pulses derived from the address bug decoding logic.

The remaining control signals that are used include (1) a START pulse applied to the ADC that resets it and starts the internal conversion process, and (2) a DONE/BUSY ADC output flag which indicates that a conversion has taken place and that the 10-bit digital output is ready. These are important control signals since they synchronize the operation of the conversion process. Analog-to-digital converters are not generally "free-running" devices that continuously convert voltages into digital outputs. These conversions take a finite period of time. It is necessary to pulse or strobe the ADC to start each conversion, and you cannot expect a 10-bit binary value to be output by the converter immediately after the strobe pulse is applied. For the generalized converter in our figure, a 21-microsecond conversion time is required. Inside our ADC, a successive approximation technique is used that converges on the unknown voltage by making successively smaller tests and comparing the results of such tests to the unknown voltage.

The DONE/BUSY flag, which indicates that the converter is either DONE (logic 1) or BUSY (logic 0), is input into the microcomputer as a single bit. Since there are six unused bits at input port 066, bit D7 is assigned to the flag. The START pulse to initiate a conversion must be a short positive pulse. It can be obtained by gating the control signal OUT with a negative device address pulse, 037, using a 7402 2-input NOR gate.

A typical software subroutine used to perform a single conversion is shown in Table 1.[2] The 10-bit binary result of the conversion is left in the B and C registers of the 8080, with the least significant eight bits in register C and the most significant two bits in register B in bit positions D0 and D1. The microcomputer spends time in the TEST loop as it checks and rechecks the flag bit while the conversion takes place. The converter we chose took only 21 microseconds, so

New Products

DRAKE WH-7 WATTMETER/COUPLER

Drake's new WH-7 wattmeter/coupler is a through-line wattmeter designed to match the styling of the TR-7 and the rest of the 7-line, but it will make a most useful and attractive addition to your shack regardless of the rig you're using. The instrument has a large, easy-to-read meter with three calibrated scales to measure forward power. There's a 20-Watt scale for low power enthusiasts as well as the more usual 200- and 2000-Watt scales. A fourth calibrated scale provides direct reading of vswr, and is switch-selected from the front panel.

The WH-7 features a frequency coverage of 1.8-30 MHz. The line impedance is 50 Ohms resistive. The wattmeter accuracy is ±5% of reading + 0.2 Watts on the 20-Watt scale, ±5% of reading + 2 Watts on the 200-Watt scale, and ±5% of reading + 20 Watts on the 2000-Watt scale, throughout the 1.8-30 MHz range. Insertion of the wattmeter in the line changes the vswr no more than 1.05:1. The power capability is 2000 Watts, continuous duty.

The wattmeter is installed between the output of the transmitter (or amplifier) and the antenna. Ordinary PL-259 coax connectors will couple directly with the SO-239 receptacles on the sensing element. The sensing element is completely removable for placement in a convenient position. It can be removed by unscrewing the four machine screws on the bottom of the cabinet which hold it in place. In this manner, the sensing element can be installed behind the operating table so that bulky coax need not be brought up. Approximately 3 feet of small, flexible cable connects the sensing element to the meter, allowing a wide range of installation positions.

There are three different types of power to consider when using a wattmeter: forward, reflected, and radiated. The WH-7 reads the sum of the radiated and reflected power, or forward power. True radiated power may be determined with the vswr calculator supplied with the wattmeter. Simply lay a straight edge across the appropriate scales of "FORWARD" and "VSWR", and read "REFLECTED" power on the right-hand scale. Radiated power is calculated by subtracting the reflected power from the forward power.

Vswr measurements may be made easily and directly with the WH-7. Just turn the selector switch to the "SET" position (full CW) and adjust the "VSWR SET" control to align the meter pointer with "SET" at the full-scale position on the meter. Then turn the selector switch to the "VSWR" position and read the vswr directly from the vswr scale.

Once you discover the convenience of a wattmeter like the WH-7, you'll never want to be without it. Whether you're in the process of matching a new antenna, making a fast band change during a contest, or performing any other activity where fast and accurate measurement of rf power and vswr is needed, you'll find your wattmeter to be your biggest helpmate and worth every penny you spent for it.

The WH-7 wattmeter/coupler's main cabinet measures 5-5/16" high, 6-7/8" wide, and 7" deep. The removable sensing unit is 2-1/2" high, 3-3/8" wide, and 2-3/4" deep. Its weight is 2-3/4 pounds, and the selling price is $89.00. Available wherever Drake equipment is sold. *R. L. Drake Company, 540 Richard Street, Miamisburg OH 45342.* Reader Service number D11.

CSC OFFERS NEW 6-MODE MODEL 4001 PULSE GENERATOR

The 4001 offers independently-variable pulsewidth and spacing controls from 100 nanoseconds to 1 second in 7 overlapping decade ranges. Two single-turn verniers provide continuous adjustment in each range. The duty cycle is variable over a 10,000,000:1 range, continuously adjustable from 0.5 Hz to 5 MHz. The control settings are calibrated within ±5% at each end of the vernier ranges. Jitter is held to less than 0.1% + 50 picoseconds.

The six push-button-selectable modes are Run, Trigger, Gate, Single-Shot, Square Wave and Complement. (The pulse spacing control is not active in the Trigger or Single-Shot modes.)

The Run mode is frequency-settable from 0.5 to 5 MHz through the pulsewidth and pulse spacing controls. The Trigger mode accepts dc-to-10-MHz signals from an external source.

The Gate mode starts the generator synchronously with the leading edge of the gate signal. The last output pulse is independent of the falling edge of the gate signal. In addition, the "One-Shot" push-button can manually activate the gate mode.

The Trigger/Gate input is TTL-compatible. It accepts 2-$V_{p\text{-}p}$ sine waves, 1-V_{peak} pulses (with a minimum width of 40 nanoseconds), and a maximum ±10-volt input. It also offers a dc-coupled 10k-Ohm input impedance.

The Single-Shot or One-Shot mode outputs a pulse each time the momentary manual push-button is depressed.

The Square Wave mode operates at up to 2.5 MHz. The square wave frequency is the reciprocal of twice the sum of the pulsewidth and pulse spacing control settings.

The Complement mode inverts the output signal.

A single-turn vernier adjusts the output amplitude over a 0.1-10-volt range. The output exhibits a maximum 400-Ohm impedance at full amplitude. Output rise and fall time is less than 30 nanoseconds.

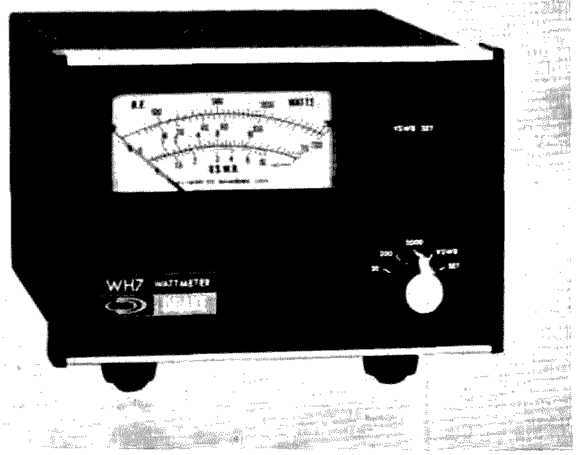
The TTL output offers a fan-out of 40 TTL loads, and is capable of sinking 64 milliamps at a maximum of 0.8 volts. TTL-output rise and fall time is less than 20 nanoseconds.

A Sync output offers a minimum output amplitude of 2.4 volts and a fanout of 10 TTL loads, and will sink up to 16 mA at a maximum 0.8 volts. The output pulse is greater than 20 nanoseconds, with a rise and fall time of less than 20 nanoseconds. The sync pulse lead time is greater than 20 nanoseconds.

For additional information, contact *Continental Specialties Corporation, 70 Fulton Terrace, New Haven CT 06509; (203)-624-3103.* Reader Service number C9.

THE 2 METER BROOMSTICK

Smithe's new fully self-contained 5/8-wave centerfed dipole for 2 meters is rather intriguingly named the Broomstick. Why Broomstick? Well, it does look strikingly like a



Drake's WH-7 wattmeter/coupler.

CSC's new Model 4001 pulse generator.

broom with an SO-239 connector in place of the bristles.

The 2 meter Broomstick is 4½ feet long and an inch in diameter. There are no protruding radials, tuning rings, or appendages of any sort, and it needs no ground system. A small hook on one end enables it to be quickly and easily hung from a drapery rod, closet pole, or picture hook, so that it is unlikely to offend even the most particular XYL or other members of the family.

For the moment, my Broomstick is hung behind the drapes of one of the living-room windows, where it is completely out of sight but still enables me to key up several area repeaters and put out a very respectable signal on simplex frequencies.

The first location I tried with the Broomstick, an inside bedroom (no windows), produced pretty good results on receive but rather poor performance on transmit. Also, for some reason, I was unable to get the vswr to 2.1:1 maximum over the entire band as specified in the manufacturer's literature. However, moving the antenna to the position behind the drapes of one of the living-room windows produced a big improvement on both transmit and receive, and the vswr came down to within the manufacturer's specifications. Although I had no way of precisely measuring the antenna's gain, on-the-air checks support the 4 dBi figure given in the specs.

The 2 meter Broomstick is not only a versatile indoor antenna at home and away, but can be used outdoors as well—it's watertight and looks like it should stand years of rain and sun and whatever else Mother Nature is likely to throw at it. A mobile mounting clamp will be available shortly. If you've been stuck with using a telescoping whip or rubber ducky at home or from hotel and motel rooms when you travel, the Broomstick will give you a very useful signal boost.

Smithe's 2 meter Broomstick is priced at $19.95 and is sold and distributed by *Smithe Aluminum, Box 442, Laurel MD 20810*. Reader Service number S80.

DRAKE DRY DUMMY LOADS

If I were ever limited to a single accessory item for the shack, I'd unhesitatingly choose a dummy load. Whether I'm tweaking up a new piece of equipment I've just built, going through the neutralization process after changing the final amplifier tubes in my transceiver, or simply retuning after changing bands, I find a dummy load indispensible.

Now, with Drake's two new dry (no oil required) dummy loads, the DL-300 and DL-1000, it's easier and more convenient than ever to have a dummy load handy and ready to use whenever needed.

The DL-300 will handle 300 Watts of rf for 30 seconds, with derating curve to 5 minutes. Maximum vswr is 1.1:1 to 30 MHz and 1.5:1 from 30 to 160 MHz. Impedance is 50 Ohms resistive, nominal. Its small size (6.7" x 2.08") and light weight (11 oz.), plus built-in PL-259 coax connector for direct connection to transceiver or transmitter output, makes it perfect for portable, mobile, or fixed station use.

The DL-1000 is larger (14" x 3.6") and heavier (2 lbs.), but it handles 1000 Watts of rf for 30 seconds, with derating curve to 5 minutes. Maximum vswr is 1.5:1 over the 0-30 MHz range. Impedance is 50 Ohms resistive, nominal. When the Drake FA-7 cooling fan is added to the DL-1000 to provide forced air cooling to the resistive element, the unit's rating limitations are expanded, i.e., 90 seconds at 1000 Watts. The DL-1000 is provided with SO-239 coax connector and rubber feet for desk or bench use.

The DL-300/DL-1000 dummy loads should be used in conjunction with the derating curve which comes with the units if power is to be applied for a period exceeding 30 seconds. Allowance must be made for adequate cooling-off periods when needed, to prevent exceeding the rating dictated by the derating curve. Failure to do so will drastically reduce the life of the resistive element. A good rule to follow is to allow one-minute cooling-off periods between use.

The DL-300 connects directly to an SO-239 connector, eliminating the need for an interconnecting coax cable. The DL-1000 should be connected to the transceiver or transmitter using a convenient length of coax cable.

With one or both of the Drake dry dummy loads in the shack, you'll find that servicing your gear is a lot easier and safer, and you'll be a lot more popular with your fellow amateurs if you use one when matching a new antenna or retuning after changing bands. If you haven't been using a dummy load, try one. You'll like it!

The DL-300 sells for $19.95, and the DL-1000 for $39.95. Available wherever Drake equipment is sold. *R. L. Drake Company, 540 Richard Street, Miamisburg OH 45342*. Reader Service number D11.

NEW DVOM IS RUGGED, CONVENIENT, AFFORDABLE

A new 3½-digit pocket-sized digital multimeter has just been introduced by The Hickok Electrical Instrument Company for electrical/electronic test, calibration, and field service applications. The instrument, designated the LX 303, contains features generally found in more expensive units, including autopolarity, autozero and automatic overage indication. A rug-

BARTG SPRING RTTY CONTEST
Starts: 0200 GMT Saturday, March 24
Ends: 0200 GMT Monday, March 26

The total contest period is 48 hours, but no more than 30 hours of operation is permitted. Time spent listening is counted as operating time. Off periods may not be less than 3 hours at a time and times on/off must be summarized on the log and score sheets. There will be separate categories for single operators, multi-operators, and shortwave listeners. Use all amateur bands from 80 to 10 meters. Stations may not be contacted more than once on any one band, but additional contacts may be made with the same station if a different band is used. Those on the ARRL countries list and in addition each W/K, VE/VO, and VK call area will be counted as separate countries (but W/K, VE/VO, and VK will be counted once only for QCA purposes).

MESSAGES:

Messages exchanged will consist of:

Time in GMT consisting of a full 4-figure group; the use of the expression "same" or "same as yours" will not be acceptable.

RST and Message Number—the message number must consist of a 3-figure group starting with 001 for the first contact made.

POINTS:

All 2-way RTTY contacts with stations within one's own country will earn 2 points, while those outside one's own country earn 10 points. All stations will receive a bonus of 200 points per country worked, including their own. NOTE: Any one country may be counted again if worked on another band, but continents are counted only once. Proof of contact will be required in cases where the station worked does not appear on any other contest logs received or the station worked does not submit a check log.

SCORING:

Multiply QSO points times total countries worked; multiply total country points times 200 multiplied by number of continents worked. Add these two totals together to obtain your final score. Example: exchange points (302 x countries 10) = 3020; country points 10 x 200 x continents 3 = 6000; final score = 9020 points.

LOGS AND SCORE SHEETS:

Use a separate sheet for each band and indicate all rest periods. Logs to contain: date/time in GMT, callsign of station worked, RST report and message number as sent, RST report and message number as received, exchange points claimed. The summary sheet should show the full scoring, the times off and on the air, and, in the case of multi-operator stations, the names and callsigns of all operators involved with the operation of the station. All logs must be received by May 31, 1979, in order to qualify. Send logs and check sheets to: Ted Double, 89 Linden Gardens, Enfield, Middlesex, England EN1 4DX. The judges' decision will be final and no correspondence can be entered into with respect to incorrect or late entries. All logs will remain the property of the British Amateur Radio Teleprinter Group. Certificates will be awarded to: leading stations in each of the

three classes, the top stations in each continent, and each W/K, VE/VO, and VK call area.

If a contestant manages to contact 25 or more different countries on 2-way RTTY during the contest, a claim may be made for the Quarter Century Award issued by BARTG for which a charge of 3 dollars US or 15 IRCs is made. Make your claim at the same time as you send in your log. Holders of existing QCA awards will automatically have any new countries added to their records. However, in view of the high volume of work which the contest manager has to deal with, it will not be possible to prepare and send out new awards or update existing awards until the final results of the contest have been evaluated and dispatched.

If any contestant manages to contact stations on 2-way RTTY with all six continents and the BARTG contest manager receives a contest or check log from all of the operators in those six continents, a claim may be made for the WAC Award issued by the *RTTY Journal*. The necessary information will be sent on to the *RTTY Journal*, who will issue the WAC Award free of charge.

INTERNATIONAL 10/10 NET CANTERBURY CHAPTER QSO PARTY

Starts: 0000 GMT
Saturday, March 31
Ends: 1200 GMT
Sunday, April 1

Work each station only once; all contacts on 10 meters. Exchange callsign, name, QTH, 10X number if any, Canterbury Chapter number if held, and your own local chapter name and number if any.

SCORING:

Claim 5 points for working the Canterbury Chapter callsign ZL3ACA. This will be used on a roster basis throughout the party by committee members who will also be using their own station calls. Score 3 points for working a station holding a 10X number and also either full or associate Canterbury Chapter membership. For any station holding a 10X number, but who is not a Canterbury Chapter member, score 2 points. You only get 1 point for working any other station on 10 meters.

ENTRIES:

Logs must be received no later than May 15, 1979. Send to: C. J. Bramley ZL3ME, 198 Greers Road, Christchurch 5, New Zealand. Please write clearly; show your name and address with your 10X number if you have one.

AWARDS:

A handsome first-place trophy to the highest scorer. A pennant to the highest scorer in each US, Canadian, Australian, Japanese, and New Zealand call area; to each Central and South American country; to each European, African, and Asian country; and to three Pacific Ocean zones. Awards are free and will be sent airmail.

NORTH DAKOTA QSO PARTY

Starts: 1800 GMT
Saturday, March 31
Ends: 2400 GMT
Sunday, April 1

This contest is sponsored by the Fargo Repeater Association. Activity will be between North Dakota and out-of-state stations. The same station may be worked once per band and mode. North Dakota mobiles may be worked again with each county change.

EXCHANGE:

QSO number and county for ND stations; QSO number and state, province, or country for others.

FREQUENCIES:

3560, 3895, 7060, 7230, 14060, 14285, 21060, 21355, 28060, 28600, 29005. Novices and Techs will operate in the middle of their bands.

SCORING:

One point per QSO. ND stations multiply total QSOs by sum of states, provinces, and DX countries. Others will use ND counties for their multiplier (53 max.).

ENTRIES AND AWARDS:

Certificates to top scorers in each state, province, and DX country, the top 10 ND entries, and top 5 ND mobiles. Mailing deadline is April 20 and all entries should be addressed to: Fargo Repeater Association, WD0CCL, 2826 Evergreen Road, Fargo ND 58102. Include a large SASE for a copy of the results.

TENNESSEE QSO PARTY

Contest Periods:
2100 GMT Saturday, March 31 to 0500 Sunday, April 1
1400 GMT to 2200 GMT Sunday, April 1

The contest is sponsored by the Tennessee Council of Amateur Radio Clubs. You may work the same station on different bands, modes, or counties. Repeater contacts are not allowed. Mobiles compete against mobiles, portables against portables. Single-transmitter entries only. No county line operations for multiple contacts are allowed. Portable stations must use a portable antenna as on Field Day. Phone and CW are all one contest, combined score!

EXCHANGE:

TENN stations give RS(T) and county; others send RS(T) and state, province, or country.

FREQUENCIES:

Approximately 50 kHz up from the bottom of each CW band. Phone—3980, 7280, 14280, 21380, 28580. Novices operate authorized frequencies.

SCORING:

One point per contact: TENN stations multiply by sum of different states plus different VE provinces plus TENN counties. Others multiply by number of TENN counties for final score. Add bonus of 200 points for each county operated from outside of home county with a minimum of 10 contacts.

AWARDS AND ENTRIES:

Plaques to TENN top score, TENN mobile, TENN portable, and out-of-state. Certificates with results to every log showing 15 contacts. Logs must

THE 73 MAGAZINE 10 METER AWARDS

The return of vigorous solar activity means that 10 meters is once again a band to be reckoned with. Ol' Sol's 11-year cycle of sunspot production is about to hit a peak, with the result that QRP 10 meter DX is possible.

Now's the perfect time to convert that old CB rig to 10. American Crystal Supply makes a variety of simple and inexpensive conversion kits, or you can do-it-yourself from the articles in 73. True appliance operators can purchase ready-made rigs from Bristol Electronics or Standard Communications. To give you an added incentive, 73 is offering two nifty Certificates of Achievement for 10 meter channelized communications.

For domestic types, there is the 10-40 Award. This one should be pretty easy—just work 40 of the 50 states. The DX Decade Award goes to DXers who work 10 or more foreign countries with a channelized 10 meter rig. We have endorsement stickers, too—the whole bit.

To give everyone an equal shot at award #1, only contacts made October 1, 1978, or after will be valid.

Well, don't just sit there. Get out your soldering iron, order some crystals, and put that CB rig on 10. This is going to be fun, so don't miss out!

RULES

1) All contacts must be made in the 10 meter amateur band using channelized AM equipment. Both converted Citizens Band equipment and commercially-produced units may be used.

2) To be eligible for award credit, all contacts must be made October 1, 1978, or after.

3) The 10-40 Award is available to applicants showing proof of contact with stations in at least 40 of the 50 United States. A special endorsement sticker will be available to those working all 50 states.

4) The DX Decade Award is available to applicants showing proof of contact with at least 10 foreign countries. Endorsement stickers will be awarded for 25, 50, 75, and 100 countries.

5) A log of stations worked, with the date, time, and type of equipment used for each contact, must be submitted when applying for each award or endorsement.

6) Each application for an award or endorsement must be accompanied by a signed statement that all claimed contacts are valid. No QSL cards need be sent, but they must be in the possession of the applicant.

7) To cover costs, a fee of $5.00 must accompany each application for the 10-40 or DX Decade Award. The fee for endorsement stickers will be $2.00 each.

8) All award applications should be mailed to: Chuck Stuart N5KC, 5115 Menefee Drive, Dallas TX 75227.

show date/time in GMT, station worked, band, mode, exchange, and score. Use separate sheets for each band with over 25 contacts. Submit a cross-check sheet similar to ARRL operating aid #6 if you have over 200 QSOs. Logs must be legible to avoid disqualification. Mailing deadline is May 1. Send business size addressed envelope to: Dave Goggio W4OGG, 1419 Favell Drive, Memphis TN 38116.

WISCONSIN QSO PARTY
Starts: 2100 GMT March 31
Ends: 0300 GMT April 2

Maximum operating time is limited to 24 hours. Phone and CW are the same contest. Any station may be worked only once using all bands 160 to 10 meters. Novices or Technicians sign /N or /T.

EXCHANGE:
WISC stations send RS(T) and county; others send RS(T) and state or province.

SCORING:
Phone contacts count as one QSO point, while CW contacts count as two QSO points. WISC stations multiply QSO points by number of states plus WISC counties; others multiply QSO points by number of WISC counties. Foreign countries other than VE and VO count as additional states. Novices score as above, then multiply total by 2.5 to get final score.

FREQUENCIES:
3550, 7050, 14050, 21050, 28050, 3980, 7280, 14280, 21380, 28580, and 20 kHz up from the bottom of the Novice bands.

AWARDS:
Awards to the highest score per state and the highest club score. Awards to be presented at the Central Division Convention in June in Milwaukee.

ENTRIES:
Logs must show date/time in GMT, band, mode, call, report, and score. Logs must be legible or will be classified as check logs. Logs containing more than 100 contacts must also be submitted with ARRL or similar dupe sheet. All entries must be postmarked before May 1. Send results to: Wisconsin QSO Party, c/o West Allis RAC, PO Box 1072, Milwaukee WI 53201.

WORKED ERIE, PENNSYLVANIA AWARD

This certificate is sponsored by the Radio Association of Erie. In order to qualify for the certificate, an amateur must prove two-way contact with ten Erie amateurs on any band in any mode or combination thereof. A copy of his QSL cards or log entries will be required as proof. A self-addressed, stamped envelope will ensure a speedy return of the award. Send inquiries or information to: RAE, Box 844, Erie PA 16512, or John Lindvay WB3IFD, 908 West Ninth St., Erie PA 16502.

WARC 1979 CW DIPLOMA

On occasion of WARC 1979, the REF is making available the CW Diploma for contacts made between January 1 and December 31, 1979. Necessary are a minimum of 300 QSOs to include: 1 station of the city of Geneva—WARC 1979, 50 French stations dealing a code number with the RST, 10 cantons HB, 5 provinces ON, 25 provinces Italy, 8 districts EA, 5 provinces PA, 15 DOK of Federal Germany, 1 station of G, GI, GM, GW, and 15 other European countries. Apply before April 1, 1980, to REF (WARC 1979), Square Trudain 2, 75009 Paris, France. Include 10 IRCs and a verified list of QSOs. Per country, a rank will be established and the first will be honored with an additional award.

Ham Help

I would appreciate it if any Canadian ham who is willing to take his portable rig to school or have about a half-dozen kids visit his shack to talk to students in another province would send a QSL card to me. On the blank side of the card, please list the bands you can use and the modes (AM, SSB, RTTY, OSCAR, SSTV), to help match you to the ham in the other province. Our Ministry of Education "school-to-school" coordinator seems quite interested in helping me match up classes and hams.

Randallstown MD 21133

Allow me to make a rash assumption: You read *73*. Now, that is not quite so unfounded; I mean, you are reading this column, right? Right. Hello, out there! Unless this is your first issue of *73*, or you are a hopeless tube buff, by now you've read about a little device known as a UART. The reason that this chip (yes, Virginia, it is an IC) is important is the subject of this month's column.

Plunging right to the heart of the matter, Fig. 1 is a pinout diagram of a popular UART, the AY-5-1013-A. Available from several sources advertising in *73*, as well as Radio Shack and Jim-Pacs frequently found in electronic and computer stores, this chip is usually priced under seven dollars. Its rather long designation is frequently truncated to a "1013," and it is pin-compatible with several other UARTs on the market.

"UART" stands for "*U*niversal *A*synchronous *R*eceiver *T*ransmitter." Now before you get all lost in that sea of words back there, let's dissect it a bit and see if we can understand it. Starting from the rear, the first word we encounter is "transmitter." OK, we are all hams, so we know what that means, right? Let's see, the antenna must go here, the key, hmmm, where do you plug in the key? Hold up, hee-haw, WHOA! This ain't that kind of transmitter. This is a data transmitter which, when coupled with its companion receiver, will allow us to convert from serial data to parallel and back again. You remember serial and parallel, don't you? We covered that last year. As you may recall, the most efficient means for transferring data long distances is in serial format. Generation, however, is best done in parallel. Last month we looked into one such technique. But we digress.

Okay, so here we have generated some parallel data, five to eight bits long, and we wish to send it. Some fancy logic and a shift register could put the data out, appending the necessary START and STOP bits, and accomplish the task. But you know, a bunch of chips, all that wiring, and remember Murphy's Law as applied to circuit complexity. No, that would be too messy; let's use the UART. To send data is rather straightforward. The chip must be configured for the number of data bits, stop bits, and parity. Then a clock of sixteen times the baud rate is applied, and the data is presented to the transmitter parallel inputs. Grounding the "send" line momentarily begins the process and, lo and behold, the data flows serially out of the UART.

The *R* stands for receiver and, while basically similar to the transmitter, albeit backwards, there are a few hookers. The data comes into the receiver serially, is converted to parallel, and is presented to the receiver output. A pair of signals is also used to state that there is data ready to be picked up, and that the data has been picked up and new data may replace it. This is frequently termed "handshaking," for what seem to me to be obvious reasons.

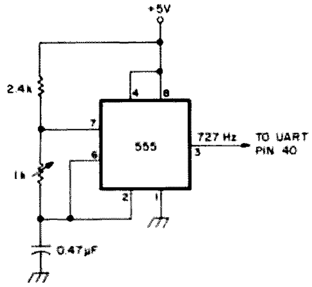

Fig. 2. 727 Hz clock.

This handshaking between the UART and the device using the data brings us to the *A*, standing for asynchronous. Realize if you will that, although the data is going by rapidly, and to your plodding visage continuously, it really is going in a start-stop fashion, with delimiters defining each character. Although bits within each character are being sent at a given baud rate, characters themselves may be sent as rapidly as the system will handle or whenever the operator decides to hit a key. This is asynchronous data flow. If the data were being sent at a known, constant rate, there would be no need for character delimiters. This is called synchronous data, and devices capable of generating either synchronous or asynchronous data are frequently termed USARTs. I'll let you figure that one out for yourself.

The *U*, of course, is for universal. I guess that means they can use them on the *Enterprise*. So that's the UART. At least you've got some idea now of what this multi-legged chip does. Let's see how to hook one up.

Remembering that we need a clock sixteen times the baud rate, dig out a 555 and look at Fig. 2. The baud rate for 60 wpm RTTY is about 45.45, and sixteen times that is roughly 727 Hz. The values shown in the diagram will give that frequency, with the variable resistor used to fine trim the output.

Fig. 3 shows how to hook up the UART itself. We are not using the receiver portion of the chip here, and that half may be safely ignored. The character to be sent is programmed by grounding the space bits on the transmitter. When the "send" line is grounded, the character will be sent out over the output line. Before we leave the UART, note that it requires not only +5 V, but also −12 V at a few mA. Although there are other UARTs not requiring this supply, we are showing it because the 1013 is the most widely available.

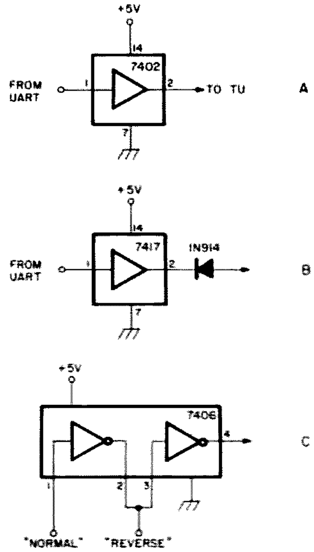

Fig. 4. Output buffers. (a) 7407. (b) 7417. (c) 7406.

The output from the UART is a TTL-compatible line that goes low on space and high on mark. Most keying schemes, including the one shown for the ST-6 a while back, use this convention. To prevent interaction with the TU's circuitry, however, one more chip will be used. A 7407 buffer, wired as in Fig. 4(a), will be used between the UART and the keyer. The 7407 is an "open-collector" buffer. That means that instead of giving a TTL high level during mark, it presents an open circuit. We then obviate the risk of feeding a voltage into a sensitive circuit, be it the ST-6 or a shift-pot keyer. A standard buffer, like the 7417, can be used with a blocking diode, shown in

RAM Scan Your KDK

—amazing flexibility for $30

This mod was made for you and me.

Art Chapman WB2JHN
30 Cymbeline Dr.
Old Bridge NJ 08857

How would you like to program and scan up to 16 frequencies with your KDK, 7400, 2036 or other synthesized rig? Utilizing six readily-available ICs, this scanner will display the scanned frequencies on your KDK's readout, give you a programmable priority frequency, be no larger than a pack of king-size cigarettes, and cost you no more than $30. Sound interesting? Read on.

The idea struck me one day while reading an ad for the 1-4 MHz scanners for the KDK and 7400. I wondered how many times those scanners would stop at unwanted repeater input frequencies, noise, and other undesirable signals. Why couldn't there be a better solution for less than $100?

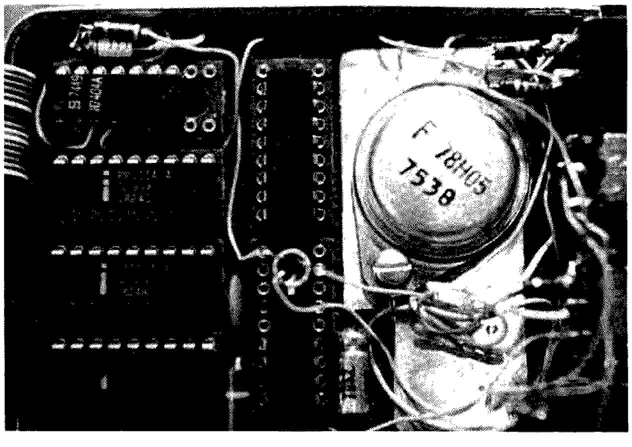
Although this article is geared to the KDK, the concepts and circuitry are adaptable to most other synthesized rigs. An understanding of the various stages I went through developing the scanner should help those with other than KDKs apply it to their radios.

Looking at the KDK's priority channel, which simply ties a set of diodes across the inputs of the decade counters, 146.52 would be connected as shown in Fig. 1.

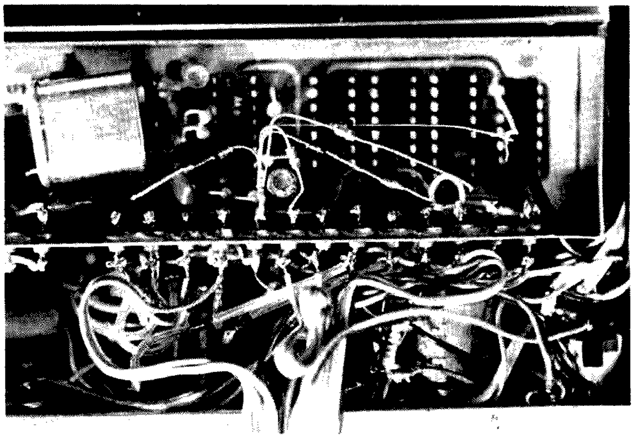
Why, then, couldn't we build a board with a series of diode arrays and scan them? A typical scanning circuit might look like Fig. 2.

With the circuit shown, IC-22S owners could easily scan their rigs. The problems with this scheme are that it takes gobs of diodes and a relatively large diode matrix board. But it still works and works well.

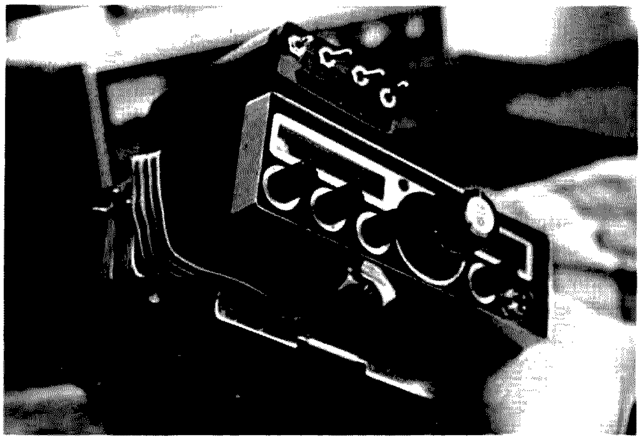
Photos by Jim Stansberry WA2HEN



Close-up of the scanner hand-wired on vectorboard. The clump of components (upper left) and the transistor (center) were a last minute fix to use the KDK's busy light and unlock light for scanner control. Note the heat sink under the 5 V regulator.



View of the tie points for the twelve memory lines into the PLL section. Note the diodes hanging in midair. The common junction of the diodes does not have any wire soldered to it. Object (lower left) in shrink tubing is an ME-3 tone encoder.



The 16-conductor flat cable was routed around the side and through the case at the front molding. The light object at the point of entrance is a folded-over business card used to protect the cable from being pinched.

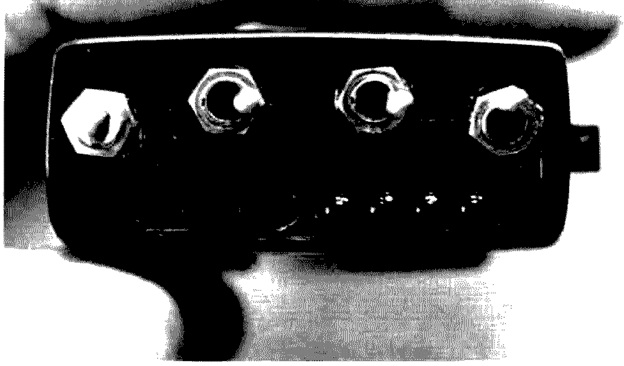
However, why use all the diodes when there is a unique device on the market called a PROM (programmable read only memory). The PROM, when properly programmed, can and does look like a diode array; however, we can put lots of those arrays into a 16-pin chip. Using the 8223 or 82S23 32 x 8 PROM, we could have up to 32 separate arrays. If we consider the 12 bits required to generate a frequency—4 for the MHz range, 4 for the 100 kHz range, and 4 for the 10 kHz range—this system will need 2 PROMs. See Fig. 3.

The PROM should be visualized as a matrix of 32 switch positions, each having 8 diodes (see Fig. 4).

By properly programming the PROM, you actually eliminate the diodes necessary to generate the desired frequency. The PROM must then be addressed in sequence (switched to the desired matrix) to connect the correct array to the 74192 decade counters. The scanner would now look like Fig. 5.

This system worked very well on a prototype, using LEDs to check out its capabilities. Although the 8223s were programmed for 32 frequencies, only 16 were used since the 74161 has 4 output lines and can address only 16 locations of the PROM.

The major drawbacks of this system are in the fact that the 8223 is a bipolar PROM and, once programmed, it cannot be changed. The scanner would now have fixed frequencies to be scanned. To change frequencies, you must replace the PROMs with another pair programmed to your new requirements.



View of the scanner's front panel.

The Final Solution

Enter the RAM (random access memory). The RAM, for those unfamiliar with this type of device, can be programmed like a PROM. However, unlike a PROM, it can be erased electronically and reprogrammed as desired. Its major disadvantage is its volatility—when power is shut off, it loses its program.

For the scanner, the Intel 2111 RAM was used. The 2111 is a 256 x 4 device, which one can again visualize as 256 switch positions of 4 diodes each. The application will use 3 of these devices to give us the 12 bits required. However, we will only employ 16 of the 256 positions. The block diagram can be seen in Fig. 6.

Construction

The final design was built on a 2" x 3" vectorboard using sockets and hand wiring. Layout should not be critical, but, for ease of construction, the memories should be side by side since much of the wiring is repetitive. The LM309 5 V regulator is kept in the scanner to keep the amount of work in the KDK to a minimum. Since the regulator is dropping approximately 7 volts at approximately 250 mA, it does get very warm and requires a heat sink. There are other ways of developing the +5 V, but this was the quickest and dirtiest—warmest, too, I'm sure.

Address	Frequency
0000	146.52
0001	146.55
0010	146.58
0011	146.67
0100	146.70
0101	147.12
0110	154.91
0111	155.19
Unlock light will go on	
1000	147.51—may be bypassed
1001	147.51—will now stop if previously busy
1010	147.54
1011	147.57
etc.

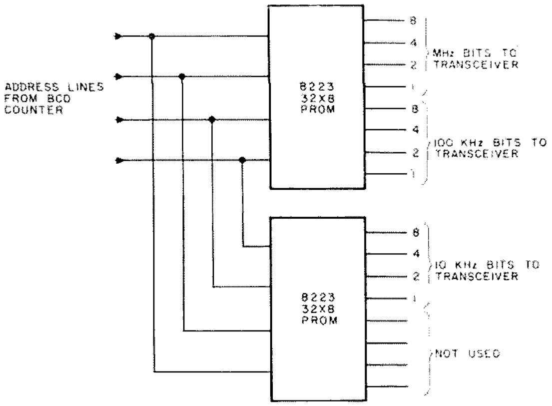

Fig. 3. PROM replacement for diode arrays.

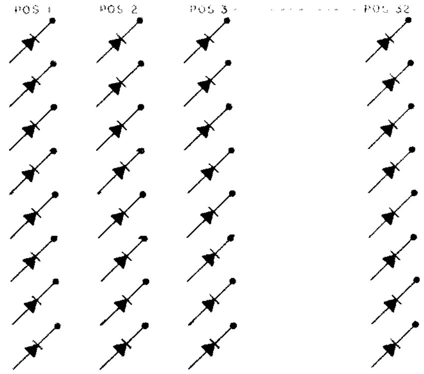

Fig. 4. Switch and diode representation of a 32 x 8 PROM.

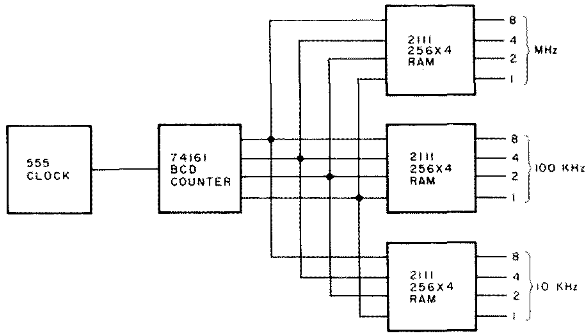

Fig. 6. Block diagram of a RAM-type scanner.

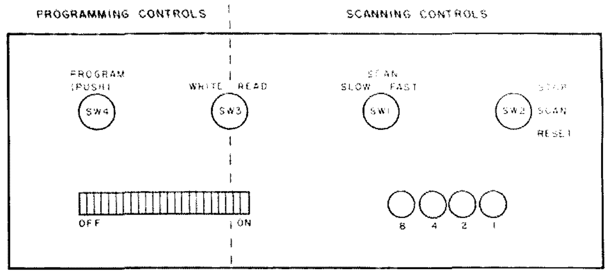

Fig. 7. Front panel layout.

For those of you who recognize it, the case is an old Radio Shack weather radio, the guts now serving as an audio amplifier somewhere else in the shack. With all due respect to Radio Shack, the scanner fits nicely into the case. I use the old volume switch for power on-off only. The other slot was filed out to make room for the address-indicating LEDs. Of course, any other case would work as well.

Try to place the switches in a convenient configuration so you will understand exactly what you are doing during programming and operation. My configuration can be seen in Fig. 7.

The program push-button and the write/read switch are together, since, to program, the write/read switch must be in the write position. To scan, it must be in the read position, thus there is an imaginary dividing line with the writing section to the left and the reading or scanning section to the right.

The 555 timer, running as an astable oscillator, generates the clock pulses for the 74161 BCD counter. The BCD 16-bit count output steps through the address lines of the 2111 RAMs at approximately one step (frequency) per second in the slow rate or all 16 steps (frequencies) in approximately 1.5 seconds. The I/O lines (pins 11 through 14) on the 2111 are tied directly to the 74192 decade counters in the PLL section. When a frequency is dialed up, a corresponding binary count is found on the input lines of the 74192s (TTL level of 1s and 0s). When SW3 is in the read position, the RAMs are in a high impedance mode, therefore having no effect on the circuit. In the write position, data can then be loaded into an address by pushing the program button.

The 7404 hex inverter inverts the address information in order to allow the proper LEDs to light when the address lines are high. (Trying to keep track of the address with negative in-

View of the scanner on top of the KDK. VelcroTM is used to hold it in place.

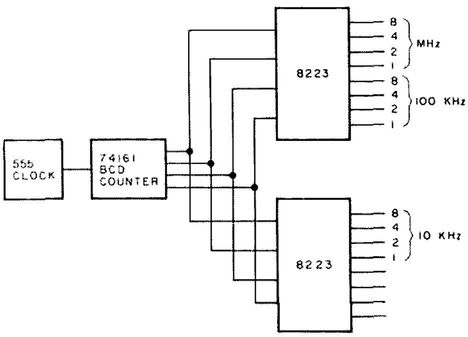

Fig. 5. Block diagram of a PROM-type scanner.

dication on the LEDs can drive you bananas.)

Installation

For those of you who have never opened up your KDK, now's the time. First, find the PLL section. Remove or lift the priority diodes from the feed-through posts. If you choose to leave them in, make sure road vibration won't allow them to move back and touch the tie posts.

Solder 12 wires of the 16-conductor cable to the 12 posts (on the outside of the PLL box) used for priority diode programming. Be sure you don't use the diode common tie point. Actually, the order of wires to the tie point is not critical, since what you put in the memory from a particular pin will come back out of the memory back to the same pin.

Solder one of the remaining wires to +12 V (the power-on switch is convenient). Solder another wire to a convenient ground. Solder another wire to the busy light (not the common line between the busy and unlock light).

Solder a wire to the unlock light (optional). Those of you who modified the KDK to high-band operation as per Al Klein W2PMX (*73*, Dec., 1977, pg. 177) will need this wire. When scanning the 144-148 MHz range, chances are you will never encounter a PLL unlock situation. However, when you scan up to 155 MHz and come back down to 146-147 again, the PLL takes approximately ½ second to lock up. During that ½ second or so, the scanner will bypass the programmed frequencies to follow the high-band frequencies. Thus, this option will stop the scanning automatically until the unlock light goes out, resulting in no bypassed frequencies.

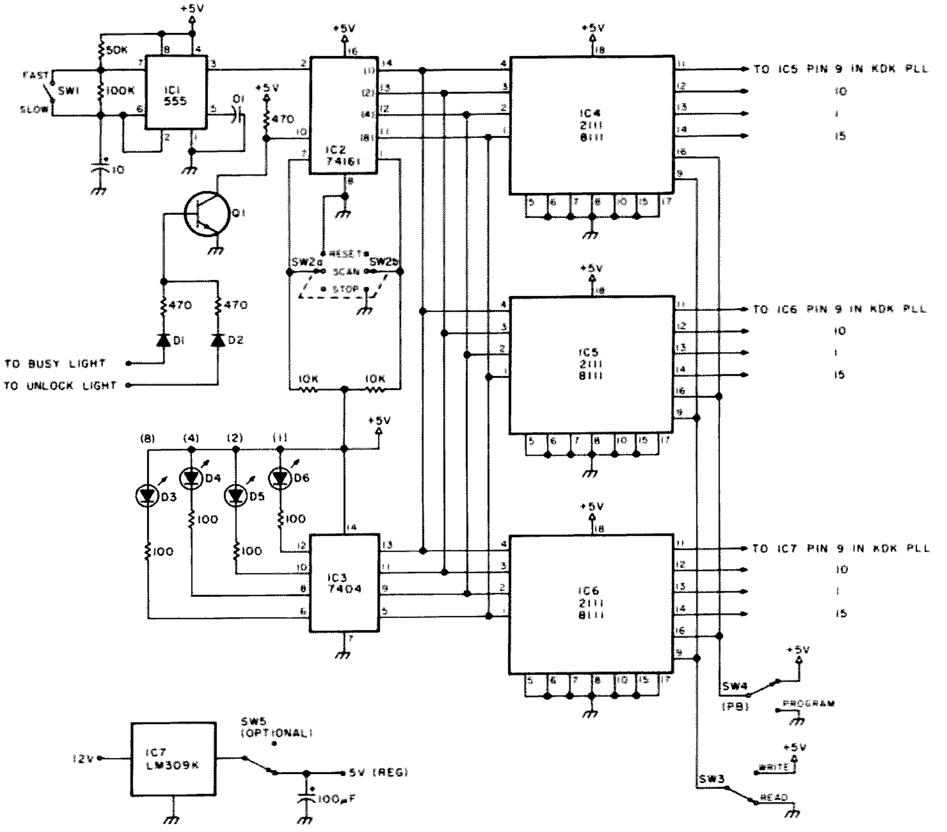

Fig. 8. KDK RAM scanner schematic. Switches are shown in scan mode. Numbers in ( ) are binary data.

Precheck

Prior to connecting the scanner to the KDK, you can power the scanner up and check the system in the following manner: Remove the 2111s from the sockets. Preset the switches: Write/Read—read; Stop/Scan/Reset—scan, Slow/Fast—slow. Turn the power on.

The LEDs should step through in a binary fashion. If not, check that the 74161 is getting a clock at pin 2. If not, check your 555 circuit.

If you're getting proper scanning at the LEDs, turn the unit off and plug in the 2111s. Use caution, as these are MOS devices and must be handled accordingly.

Operation and Programming

Preset the scanner controls to the following: Slow/Fast — slow; Write/Read—write; Stop/Scan/

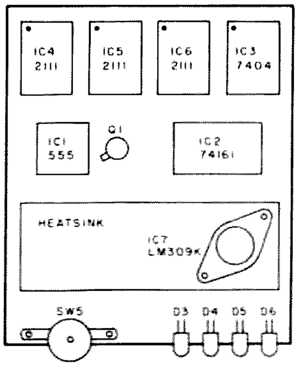

Fig. 9. Vectorboard layout of components.

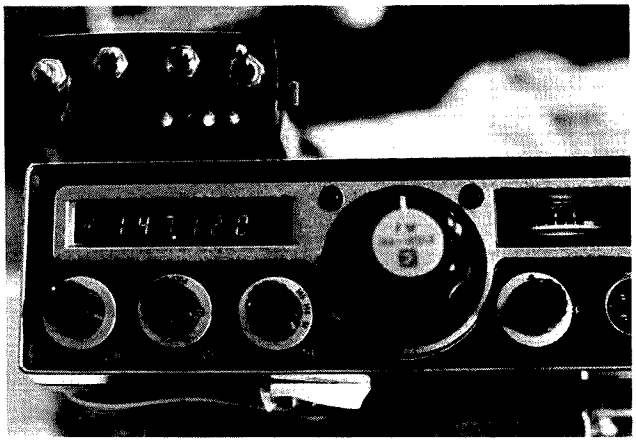
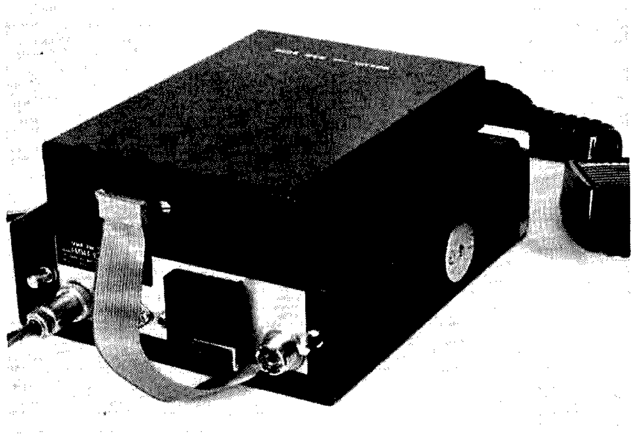
Parts List

IC1	555 timer
IC2	74161 or 74LS161
IC3	7404
IC4-6	2111 RAM (may use 2111A, 8111, 8111A any speed)
IC7	LM309K +5 V regulator
D1, D2	General-purpose silicon diode
D3-6	Any LED
Q1	Any general-purpose silicon transistor
SW1	SPST
SW2	DPDT center-off
SW3	SPDT
SW4	SPDT push-button
SW5	SPST (on-off, optional)

Resistors and capacitors as required per schematic.
16-conductor ribbon cable as required for Interfacing.
Printed circuit boards are available for $9.50 from: Circuit Works, 1118 7th Ave., Neptune NJ 07753, phone (201)-774-1811. 2111 RAMs are available for $3.50 from: Williams Electronics, 1863 Woodbridge Ave., Edison NJ 08817, phone (201)-985-3700.



Close-up view of the scanner on top of the KDK. For those who notice the difference, this KDK is not the standard U.S. import version. The Japanese version covers only 2 MHz and has no repeat mode. Note that the repeat Up-Simplex-Down switch says Lo-Off-Hi. The toggle switch was replaced with an identical MHz rotary switch having 6 positions and two poles. The extra pole was used to high-band the KDK. The rig was modified for repeater use and broad-banded to 4 MHz operation.



The flat ribbon cable is socketed on the back of the scanner and fed between the cover and the rear of the chassis and under the speaker mounting plate where it mates with a mounted 16-pin IC socket. The socket is then wired accordingly.

Reset—reset; scanner Power—on. The KDK squelch should also be on.

Dial up your desired priority frequency. Hitting reset will automatically reset the 74161 to address 0000 in the RAMs, thus giving you instant priority. Immediately flip the switch to stop, and note if address 0000 (no LEDs lit) remains.

Push the program button. Flip the Reset/Scan/Stop switch to scan to allow the LEDs to move to address 0001. Flip back to stop immediately. If the station just programmed is busy, the busy light won't let the address advance. Therefore, dial up the next desired frequency, push the button, and step the address. Continue until you complete all 16 frequencies, if desired.

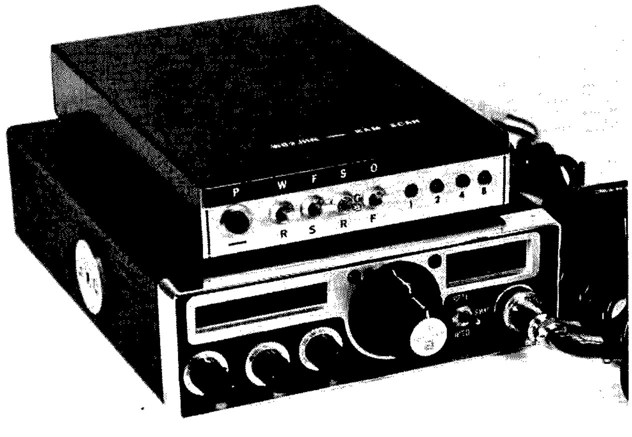
Switch the control switches to the following: Write/Read—read; Slow/Fast—fast; Stop/Scan/Reset—scan. The KDK MHz switch—priority. The scanner should now begin scanning the KDK. The digital display will also show the frequencies while scanning. If there is a desired frequency you wish to transmit on, flip the Stop/Scan/Reset switch to stop, switch in your offset, and transmit.

For those of you who use 5 kHz stations, program 5 kHz low—146.62 instead of 146.625. Instead of scanning in the priority mode, scan in the 144 MHz mode, making sure you are set to 000 on the kHz dials. If the scanner then stops on 146.62 (which it should), simply pull the 5 kHz knob if you desire to stop on that frequency and transmit.

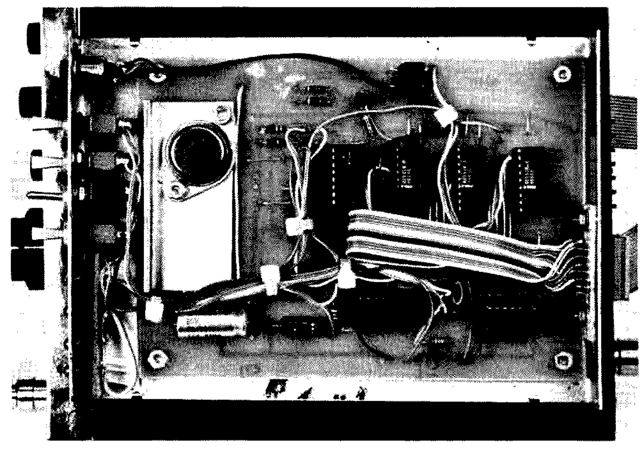
Caution

If the station you just programmed is busy, the busy light will not allow the address to advance. Therefore, you will have to reverse the process for the next frequency by changing frequency first and then stepping the address. It's not as confusing as it sounds.

If you only choose to program a portion of the 16 positions, you will find erroneous data displayed at the unprogrammed addresses. Some of these positions will actually cause the receiver to scan frequencies between 140 and 155 MHz. If this happens and the vco has not been compensated properly, the unlock light will go on and the receiver will stop scanning. So, for all



The scanner built by Felix Foggia WA2OFD. Felix chose the PC board route and housed the unit in a 5" x 7" x 3" enclosure cut down to 5" x 7" x 1".



View of the PC board mounted in the chassis.

unprogrammed positions, program into memory an unused frequency such as 146.00.

An easy way to skirt this problem is to dial in 146.00 and scan at a fast rate while you're in the write position and the program button is pushed. The result will be all 16 addresses programmed in 1-2 seconds. Then proceed with normal programming.

If using W2PMX's high-band modification, which, incidentally, works beautifully with the scanner, you will find that, as previously mentioned, the unlock light may come on if you change too many MHz in one step. Even though the unlock light holds the scanner, I have noticed that the following frequency might not stop the scanner if busy. To resolve this condition, I program the frequency following the last high-band frequency for two addresses. See Table 1 for an example.

Basic Drawbacks

The unit as designed cannot program 5 kHz frequencies. If one really wants to get into the KDK and add a few more gates and another RAM chip, it could be done. I didn't think it was worth it.

There is no delay designed into the system. When a repeater with a short squelch tail drops, or a simplex transmission ceases, the scanner will continue immediately. A delay would add another IC and transistor plus associated circuitry. I have found that a scan rate of 16 channels in approximately one and one half seconds pretty much allows you to return to the dropped channel without missing much, provided no other channel is busy. I resolved this by always leaving the KDK in a simplex transmit mode. When a channel is busy and I want to scan past it, I just tap the mike button in low power. This causes the busy light to drop out and the scanner continues. Actually, the transmitter never gets to turn on, either, so there is no interference.

A final drawback is volatility—semiconductor RAMs lose data when power is disconnected. A nicad pack would eliminate this problem. However, at a current drain of approximately 250 mA, you'll need a hefty battery pack. The computer manufacturers face this same problem—you're not alone.

Applications to Other Radios

I have not had the opportunity to delve into the TR-7400, FM-DX, FM-28, HW-2036, etc., but, if you want to, look for some sort of BCD counters—3 sets, MHz, 100 kHz, and 10 kHz. Using a voltmeter at the inputs, dial up various frequency configurations, looking for TTL voltage level changes. If you have them, the scanner should work for you. The problems you then have to solve are:

1. How can you stop the scanner. If you don't have a busy light, maybe you could use the squelch circuit or S-meter.
2. Since there is no priority channel, you'll have to program your scanner as per the instructions and then dial up 144.00 to scan. The memory will then add data to the binary equivalent, thus giving you the proper frequencies.

Well, there you have it. You should encounter no problems if you wire it correctly. I had no problems getting mine to work during the prototype stages, once I understood what I was doing. Include an SASE with all correspondence, please. ■

The NCX-Match

—build something useful

Low cost and high flexibility.

Rick Ferranti WA6NCX/1
215 Herrick Road
Newton Centre MA 02159

The need for a good rugged transmitter matching device seems to be increasing almost daily. More and more advertisements have appeared in *73* and elsewhere detailing ultimate transmatches, miniature transmatches, and transmatches with other goodies thrown in (like swr bridges, power meters, antenna switches, etc.). The one thing that all of these devices have in common is a high price tag. Why should a simple thing like a coil and capacitor be so expensive? After all, it's an easy matter to home brew your own transmatch, and you'll have the joy of using a device you built yourself.

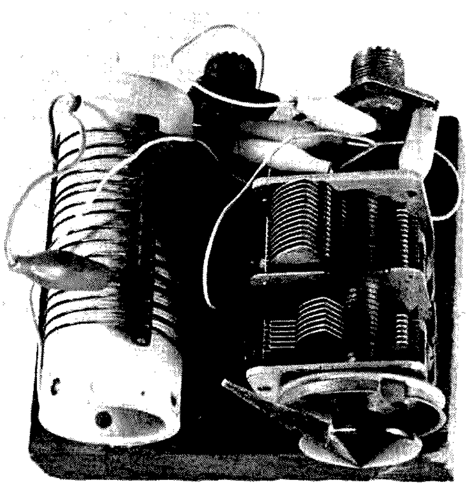

Photo A. Original nonclassy matching unit still works fine after 7 lucky years. When properly adjusted for a 1:1 swr, it will take 200 Watts PEP. Note the plastic dial pointer on the capacitor; this keeps your fingers off the rf voltage when you're tuning up.

The increasing popularity of transmitter matching equipment stems from a multitude of needs: Novices and Techs are on the increase, apartment dwellers need simple antennas requiring a proper match to the rig, solid-state finals require 50-Ohm impedances if they are to work at all, and frequency-limited antennas can often be coaxed beyond their normal bandwidth with a matchbox.

Two models of transmatch will be discussed here; the first is so easy to build that you can use it by the time you finish reading this article. The second is a bit more fancy and much more rugged, with a good deal more aesthetic value thrown in. Both have the following advantages: They'll match anything to anything, they'll take almost any barefoot rig (200-Watt class), they're low cost and the parts are easily available, and they are extremely flexible so that you can do all kinds of experimenting with tuned circuits and antennas.

Simple Beginnings

I'm still using the first transmatch I ever built—you can see this glorious contraption in Photo A. It's seven years old and still going strong. Small and easy to carry or ship, it works just fine. Basically, you wind a coil of wire on any available form (plastic pill bottle, cardboard or PVC tube, ceramic core as in the photo, etc.) and leave space between windings for an alligator clip to clamp to the wire. If you use insulated wire, scrape away the plastic or enamel at the tap points. A pencil or dowel of wood or plastic can be slipped under the windings as you go to raise them up so that the clip can firmly grip the wire. As you can see in the photo, I fit 16 turns of wire on the form, which is 1½ inches in diameter and 4 inches long.

The capacitor part of this simple device is a broadcast-band variable ripped from an old ac-dc tube set, with both sections in parallel, giving about 500 pF total capacity. Blow the dust from the plates so that they won't arc when you use it. If you can, save the plastic pointer which may have come with the radio or epoxy a plastic

tube to the shaft—you don't want to touch the cap when you're tuning up!

The rest is easy. Mount the coil and capacitor on a piece of wood, add two SO-239s (with their grounds tied together), and use clip leads to connect the two components in various configurations. Everything should be clear from looking at the photo and Fig. 1.

Of course, this thing is very flexible. You can hook up various configurations of "L" matches, loading coil or series capacitor matches, or even series or parallel-tuned circuits and traps. Some suggestions are in Fig. 2. I've found that the basic "L" configuration, with the series coil and the cap from antenna to ground, works with almost any long- or random-wire antenna—see Fig. 2(a). Put the swr bridge in the transmitter side of the line, excite the antenna with a little rf (enough to get a reading on the meter—but *listen* before you tune up on the air), and run the capacitor quickly through its range. If you get a shallow dip in reflected swr, adjust the coil tap and try for a deeper null in reflected power while swinging the capacitor around again. Continue until your swr goes down to 1:1. Remember that a low swr will let you run higher power to the matcher without arcing (I've had no problems with my FT-101B), so tune the matchbox on low power first, and then pour on the juice.

Two other things: If you can't get a dip anywhere for any tap on the coil, change the configuration (move the cap to the other side of the coil, etc.) until you get a low swr. The other thing to remember is that no matching device increases the efficiency of your antenna. It only allows your transmitter to see the load it likes so that the thing operates properly. As such, it allows you to load the rig where otherwise you may not be able to do so.

Getting Classy

Of course, I wasn't satisfied with my first transmatch, since it isn't very rugged and doesn't look like anything particularly beautiful. I decided to build something really snazzy, but with little cash outlay. The design includes a sturdy metal case, an infinitely-variable roller inductor coil, high-voltage variable capacitors, a built-in swr bridge, a low-pass filter, a frequency counter or oscilloscope output, and provision for greater flexibility by the addition of external coils, capacitors, or other components. The result, a cross between the rack-mounted monsters of yesteryear and the sleek goodies of today, is shown in Photos B and C.

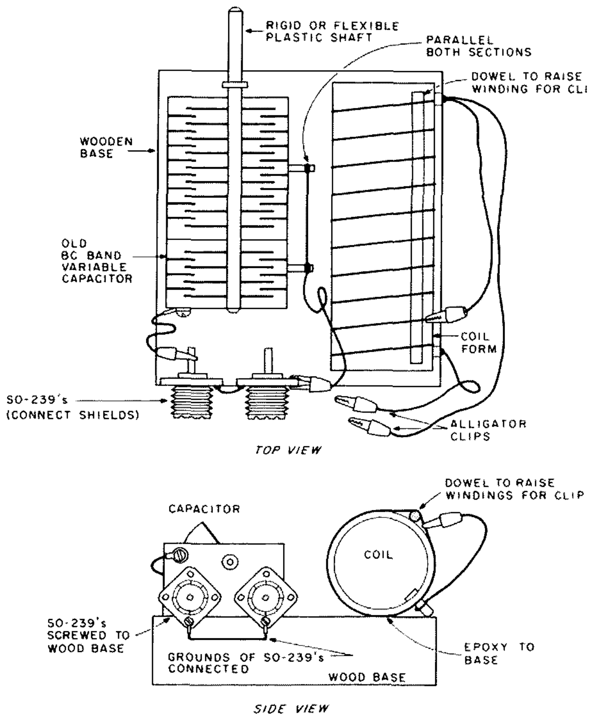

Fig. 1. Construction plans of the simple transmatch.

Parts

The perennial question for any builder is where to get the parts needed at a reasonable price. In this instance, fortunately, the case and many components are readily available on the surplus market. Write a note to Fair Radio Sales Co., P.O. Box 1105, Lima, Ohio 45802, and ask for their latest catalog. In it, they'll

Photo B. The NCX-Match. The swr meter need not be calibrated since you're tuning for a minumum at all times.

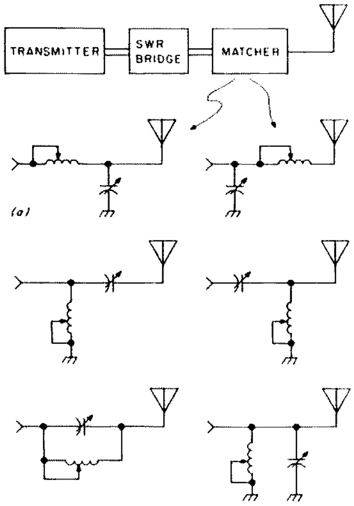

Fig. 2. Hookup diagram and suggested configuration possibilities to match anything to your rig. (a) is the one which almost always works, so try it first.

have just what you need under the heading "Parts Bonnaza" (a curious misspelling which has been in their catalog for years). On page 16 of catalog WS-77, you'll see the plug-in tuning units used in BC-191/BC-375 transmitters. I have a list of the parts in these gems, and the one you'll want to order is the TU-7-B 4500-6200 kHz unit, which has coils, an antenna switch, variable and fixed high-voltage caps, a vernier dial, a right-angle drive, and a beautiful outer case for $5.95 (brand new). It only weighs 15 pounds, so the UPS shipping charge will be around $3.00.

The tuning unit has the two large variables you'll need (each about 120 pF), and two 5000-volt, 400-pF fixed capacitors which you can save as auxiliary plug-in range extenders. Of course, you'll be using the inner case (save the outer one for another project, or use it to make a larger model of this matcher). The only other main components you'll need are the roller coil and a front panel piece.

Fortunately, Fair Radio Sales and local ham flea markets still have the incredible ARC-5 series "Command Set" transmitters. They must have built ten of these things for every man, woman, and child in the U.S.! If you can find the roller coil from the ARC-5 series (this is what I used), you're all set. If not, Fair Radio Sales has them, as well as other roller coils—check pages 9 and 16 of catalog WS-77 and page S77-37 of the catalog supplement. It doesn't matter if the rest of the transmitter is destroyed—all you need is the roller coil—so you may be able to get some junked chassis for a low price, particularly at a flea market table.

Besides the case and the roller coil, you'll also need a ¼-inch-thick aluminum panel for the front of the case. Check around at a scrap or sheet metal place and you should be able to find one and even have it cut to size for a reasonable price. The panel should be fairly thick so that the capacitors and roller-coil dials don't shift around with pressure.

Why do you need a front panel when you already have the case? Simply because you're going to strip all the parts out of the BC-375 unit, and that's going to leave its front panel full of holes. It does make a good template for the six screws which will hold the new panel to the case. By the way, save everything you take out of the tuning unit, including the screws. You need the capacitors and their mounting insulators, the handles, shaft couplings, and fixed capacitors, as well. If you want to do so, you can use that beautiful heavy-duty ceramic rf switch as an antenna switch in the matcher. It's a nice convenience which I probably should have added to my NCX-Match when I built it a few years ago.

You'll notice that the case's top and bottom panels are well ventilated with eight sets of holes drilled through them. I found that dust tends to settle on the caps and coil inside because of this unnecessary ventilation, so I glued thin clear plastic sheets under the holes to block out the dust. The top panel should be the one

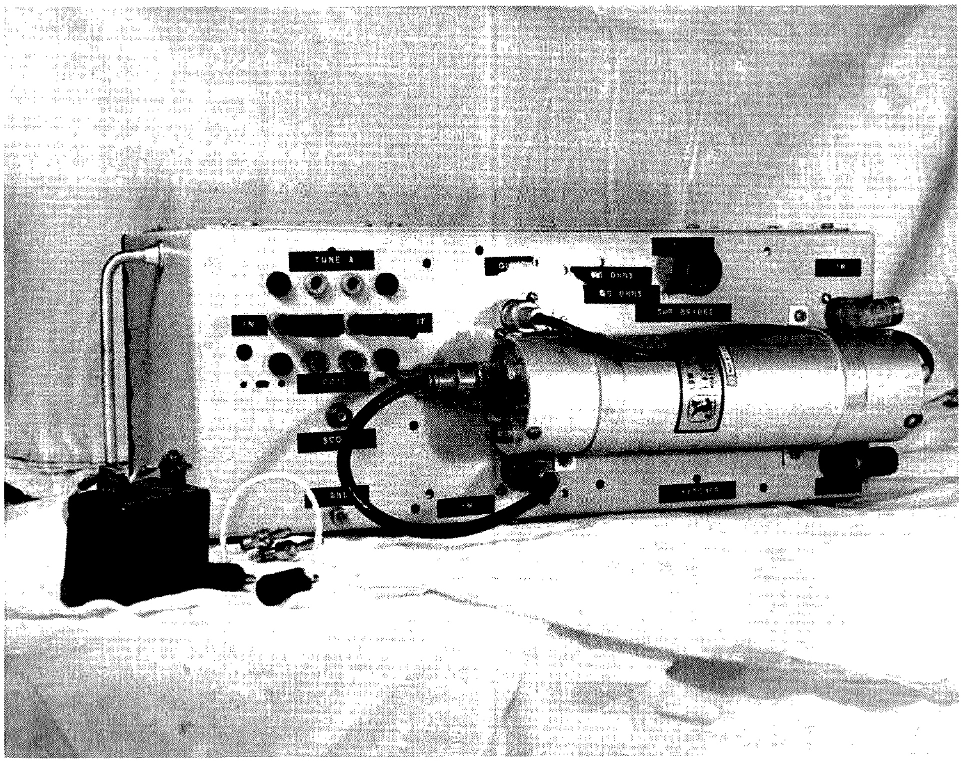

Photo C. Rear view of the matchbox. The large fixed capacitor on the left (removed from the original BC-375 tuning unit) can be plugged in the matcher jack matrix to add 400 pF. The null pot on the swr bridge above the low-pass filter has 50-Ohm and 75-Ohm calibration points marked for easy reference.

with the small notch cut in it, while the bottom panel has a long narrow cutout (originally for the plug-in connector).

You'll need a counter-type dial for the inductor. I found that big dial in the photos at a local surplus store for $2.00. If you can't get a counter dial per se at a reasonable price, just use a crank-type spinner knob. Then you can use a rubber pulley arrangement and the turns counter from an old tape recorder (they're advertised as surplus in *73*, or check out page 56 of the June, 1977, issue for more ideas on how to reset the roller coil quite accurately). The hardest part of building this whole contraption was the mechanical coil arrangement. As you can see in the photos, I used the gears from the original ARC-5 and drilled holes to match things up accurately. Take your time; you'll be rewarded with a smooth-running adjustable inductor.

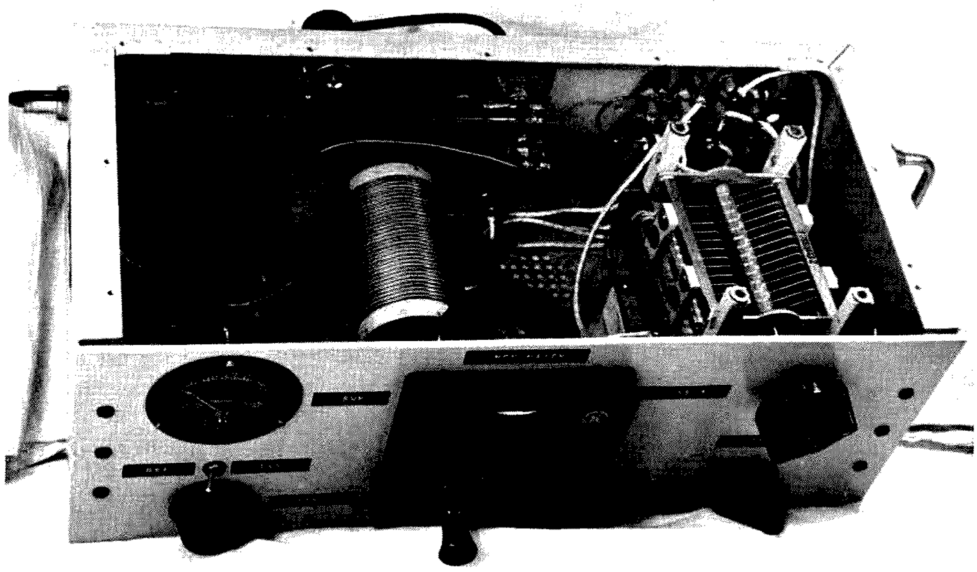

Photo D. Rear view of the matcher showing the swr bridge element, the roller and scope pickup coils, capacitor mounting, and the plug matrix.

I added an swr bridge to my unit, the details of which can be seen in Fig. 3 and Photos D and F. It's a version of the "Varimatcher" in *QST* for May, 1966. The sheet metal can be cut from a cookie sheet, and you can get the ¼-inch copper tubing from a plumbing supply house. Remember to keep things symmetrical and it'll work fine. The hardest part is taking the inner conductor of a piece of RG-58 or 59, soldering a thin wire to its center, and sliding it through the copper tube until the thin wire can be pulled out of the slot you've filed in the middle of the tube. This wire gets connected to the arm and one end of the 100-Ohm potentiometer (carbon—not wirewound!). The schematic in Fig. 4 should make construction a little clearer.

Calibration of the bridge is simple. Put a 50-Ohm dummy load or 51-Ohm, 2-Watt carbon resistor across one SO-239 and apply a Watt or so of power on 10 meters. With the bridge in the reflected position, adjust the null pot for the least indication on the meter. This is your 50-Ohm calibration point. If you want to use the bridge for 75-Ohm lines, simply replace the 50-Ohm resistor with a 75-Ohm unit. I calibrated my bridge for both impedances and can change them with a twist of the knob.

I liked the Varimatcher style because of its ruggedness and versatility. Alternately, other bridge

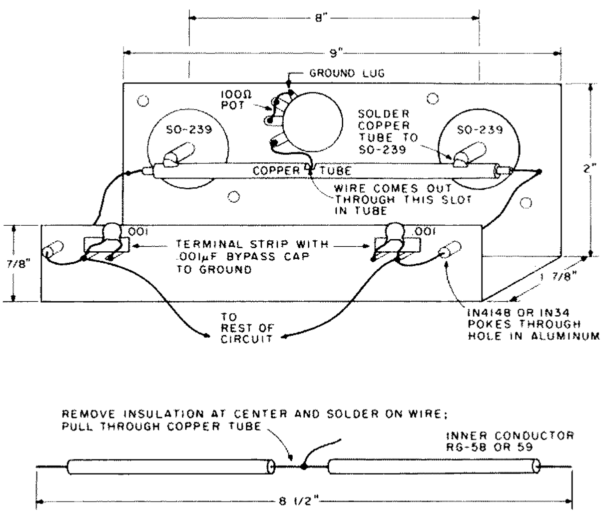

Fig. 3. Sheet metal layout and pickup element plans for the Varimatcher swr bridge.

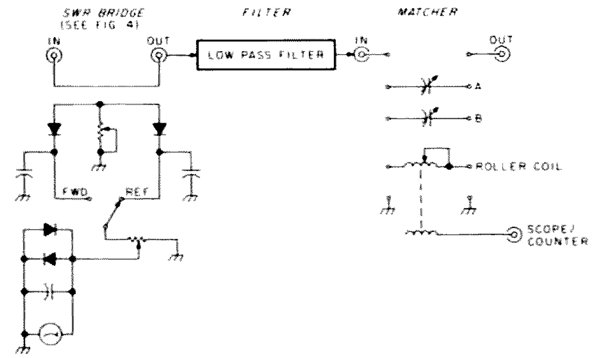

Fig. 5. Schematic of the entire matchbox showing independent swr bridge, filter, and matching elements.

construction techniques could be used, or you could simply dismantle a commercial bridge and mount its innards inside the matchbox.

Mounting and Wiring

As I mentioned before, the hardest part of building the unit is making the roller coil merrily spin as you turn the front panel crank. As you can see from Photos E and G, I mounted the original ARC-5 gear on the shaft of the turn-counter crank and secured the actual roller coil and coil tap to the bottom plate of the case.

The large air-variable capacitors can be mounted to the top and bottom case covers with their original ceramic standoffs. I used an insulated coupling for the front panel shaft of one of the capacitors; on the other, a metal coupling and insulating fiber shaft was used. The point is to keep the rotors of the caps from shorting to the case or from giving you a jolt of rf while you tune up.

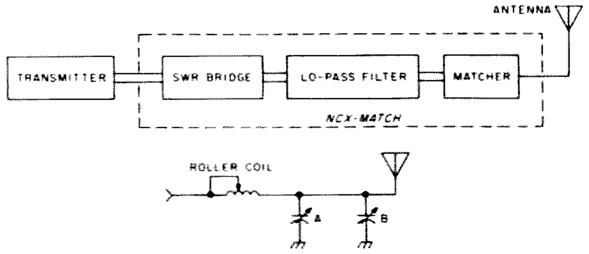

Fig. 6. Hookup diagram and suggested first configuration for the NCX-Match.

The meter was mounted in a large hole cut carefully with a coping saw, as was the counter dial for the coil. It takes a bit of patience to slowly saw through that thick aluminum plate, and the roller dial needed a very odd-shaped hole! The low-pass filter, an E.F. Johnson unit in this case, was mounted to the rear panel with the hardware supplied with it. I secured the swr bridge element to the case with long screws and lockwashers passed through the mounting holes of its SO-239s.

A useful added feature of this matchbox is the scope/counter output visible in Photo C. The smaller coil near the roller inductor and directly below the swr potentiometer in Photo F serves as the pickup element. I simply wound a coil of hookup wire on a Bakelite™ form and glued it near the roller coil so it would sniff a bit of the rf energy flying around inside the case. One end of the coil is connected to the BNC jack on the rear panel, the other end is simply left free on the coil form.

The means I used for switching various coils and capacitors in and out of the line is a matrix of 12 banana jacks spaced the standard 3/4 inches apart, as you can see in Photo C. The four corner jacks (black) are connected to ground, and two others are the input and output of the matcher. Two each down the center of the matrix connect to the two capacitors and the coil. Thus, by jumpering various connectors at the back of the matcher with either stacking shorted double banana plugs (as in the photo) or with wires with banana plugs at their ends, one can make any configuration of the coil and capacitor desired. You may also notice a large fixed capacitor with banana plugs on fly leads fitted to it in Photo C. This can be plugged into the rear panel jacks to add more capacity, or to make even more complex configurations. Of course, external coils can be added in the same manner. Thus, you can make pi networks,

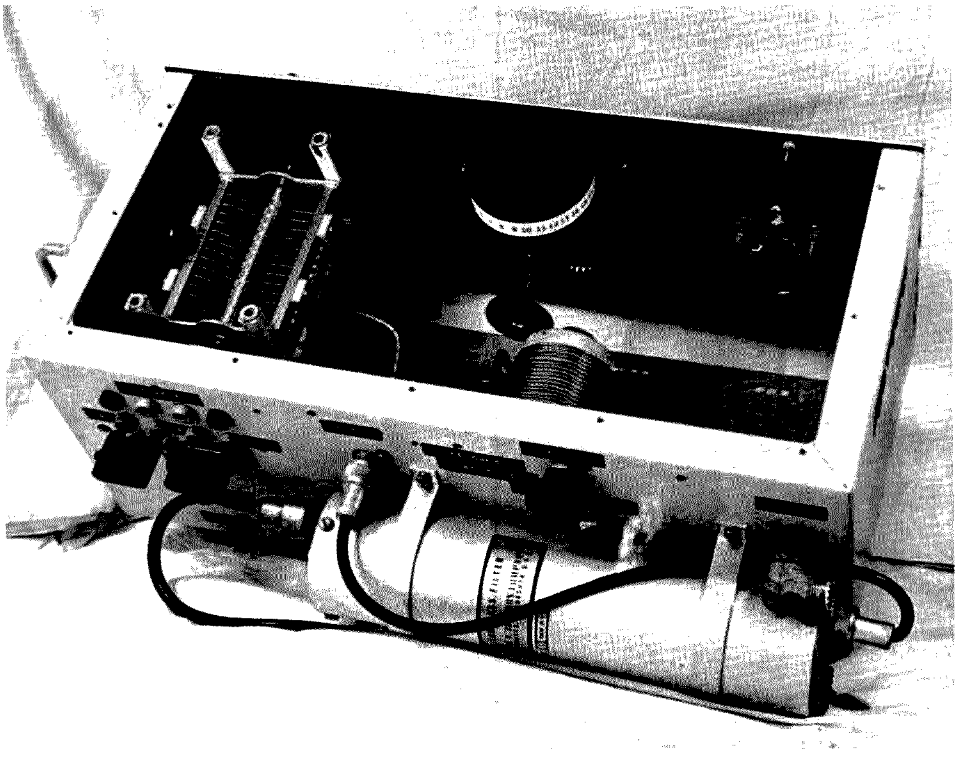

Photo E. Front inside view of the NCX-Match. Notice dual banana plugs installed on the matcher jack matrix (now configured for capacitor B to be in series with the antenna).

tuned circuits, differential capacitor circuits, and all kinds of configurations by simply plugging in jumpers. A glance at the schematic of the matchbox (Fig. 5) makes this clear.

I haven't had to use external components with the matcher since the "L" configuration with both internal tuning caps in parallel takes care of all the capacity needed for most random-length wire antennas. You'll probably find, as I have, that the roller coil has about five times more total inductance than you'll ever need, so external coils aren't necessary at all.

A few notes on the matrix of jacks may be helpful. Once, I was running 125 Watts AM (plate modulated, of course) with a DX-100 on 160 meters, and the insulation on one of the panel banana jacks started to bubble and smoke! I've long since sold that wonderful Heath monster rig, and SSB has since caused no insulation problems. However, if you worry about such things and run a lot of power on RTTY or another continuous mode, you can mount uninsulated banana jacks on a Bakelite™ or Teflon™ sub-panel and attach this so that it pokes through a large rectangular hole cut in the rear panel. Teflon™ or Bakelite™ will certainly solve any dielectric heating problems.

Wiring up the unit can be done two ways: Use heavy solid wire like in the original BC-375, or use stranded heavy wire with fiberglass insulation as I did. I chose the later method because it was easier to do, and because, when I was disassembling the tuning unit, I discovered a 40-year-old cold solder joint between the original solid heavy wire and a capacitor! Not wishing to duplicate such a feat (who were the poor guys who wired up these things anyway?), I used standard wire and a big soldering iron (100 Watts). I've had no problems with arcing with the fiberglass insulated wire.

Don't forget to save one of the original handles from the tuning unit to mount on your new matchbox. It's handy for carrying the thing around on field day. Also, do give the case a good coat of paint before assembly. When I built my unit almost five years ago, the only panel labels I had at my disposal were those embossed plastic jobs. Although they look decent with a symmetrical panel layout like the one you see in the photos, you can do better with rub-on lettering sets, particularly the kind with whole electronic terms already spelled out for you.

Tune-Up and Use

Connect up your matchbox, swr bridge, and lowpass filter between the rig and antenna as shown in Fig. 6, with the matcher configured as in the diagram. The reason for this hierarchy in element order is that the transmitter should be the one to see 50 Ohms as indicated by the swr bridge, and the filter should also see 50 Ohms to work properly. The matcher itself is the thing to fool all those other 50-Ohm devices into thinking that your weirdo antenna is really a dummy load. Hence, it goes closest to the antenna.

As you can see in Photo C, I simply used two short lengths of coax (with connectors attached) to connect the various elements in the matcher. The swr bridge, filter, and matching network proper can all be used independently if desired—an added bit of versatility.

This matchbox is tuned exactly as the previous unclassy model, with the extra convenience of a rotary coil as an infinitely-variable inductor element. Try the "L" configuration first, as suggested above, swinging the capacitors and coils through their ranges while applying low power. Look for a dip in reflected power and tune to minimize the reading. If you can't get a null, change the jumpers at the rear panel and try a new configuration. Soon you'll be able to load up everything from your window screen to a 1200-foot longwire.

This sturdy matchbox drew very flattering comments at a home brew club meeting some time back, and it still looks and works great. If you need a good rugged transmatch and don't want to spend a fortune on commercially available models, give this one a try. You'll have a good time building it up and will be rewarded with a fine piece of useful equipment. You may even want to modify your call so that it ends with an "X"—"X" for "trans"—hence the NCX-Match. ■

The Memorizer Goes to MARS

—expanded frequency coverage

A step toward the perfect FM rig.

One of the newest offerings in the field of 2 meter FM is the Yaesu FT-227R Memorizer. This unit became available at local dealers in late December, 1977, and I purchased one on December 26 as a one-day-late Christmas gift, although I am normally a little slow to buy new products until they've been proven in the field.

As a member of Air Force MARS, I had hoped for a new rig that would permit operation on our local MARS repeater, but this was unlikely with the new Yaesu, although it did a beautiful job on the 144-148 MHz portion of the band for which it was designed. The rig was engineered to preclude operation out of the amateur band, which seemed like a fact I would have to live with.

The bright red display would clearly read out any frequency from 144 to 148 MHz, but nothing else. After carefully reading through the superb owner's manual, the needed information for a modification finally came to light on pages 18 and 19. The key paragraph states that Q711 (MC14081B) limits the high end of the rig and Q712 (MC14028B) limits the low end of the rig and cut off Q713 (2SC735Y) to prevent transmissions out of the amateur bands. By tracing the circuit through the diagram on page 19, it became apparent that changes were needed to pins 3 and 6 of Q712. The phase locked loop (PLL) board was noted as being on the top side of the rig.

I carefully removed the top of the rig and noted that the PLL board was under a cardboard cover at the front of the rig. This cardboard was lifted by the removal of three screws, and I was looking at the underside of the board. A red wire came from pin 3 and a blue wire from pin 6. These were removed from these pins and resoldered to an adjacent ground, which ends the modification.

Now the crucial test came—to see what had been accomplished. My rig now displays all frequencies from 142.000 through 149.995 MHz, though transmit is possible only from 143.05 through 149.995 MHz. This frequency spread allows me to operate on the AF MARS simplex frequency and to monitor the output of the AF MARS repeater. The modification allows full operation on the Army MARS repeater and should prove very useful to many MARS members.

This is my first Memorizer modification, but it should open the door to other ways to make this the perfect FM rig. I would welcome correspondence on other modifications or further expansion of this modification (enclose an SASE, please).■

Build a Hybrid Capacity Meter

—digital circuitry, analog display

Test your junk box.

Like many other electronics enthusiasts, I like good buys on bits and pieces of electronic equipment and parts. I also accumulate a lot of "junk." Among these treasures are many unidentified capacitors. This identity problem makes them almost useless.

There are many good circuits for measuring capacity, but most of them use the same design theme—a generator with multiple frequency selecting components. If the tester has 5 ranges, there are 5 capacitors and 5 resistors, probably variable, and the switch to select the desired range. This is an acceptable method, but you may have many components that can change value and affect the accuracy of the measurement.

The circuit described here is similar in some respects to the well-known analog tester, but it uses a different method of frequency (range) selection. In this circuit, I have one clock frequency, approximately 200 kHz, that generates the necessary frequency for the ranges. Instead of using RC circuits for each range, I use 74LS90s for the decade change. The advantage of this is that there is only one frequency-determining RC network, and this is adjustable from the front panel. This means that the instrument can be calibrated on one range and be accurate for the other ranges. With the low cost of ICs, the price of this instrument compares favorably with the other types of instruments.

How It Works

The generator is a 555 oscillating at approximately 200 kHz. The frequency is adjusted by R2 when calibrating prior to use or during use, if a reading is doubtful.

The output of IC1 is used for the 0-to-100 pF range and is also used to clock the first 74LS90. The output of IC2 (pin 11) is the 555 frequency divided by 10. This frequency is used for the .001 full-scale range. The remaining 74LS90s operate similarly. Each division by 10 is the frequency for the next larger decade of capacity. The 74LS00 was added as a buffer. Since it would be wasteful with the other gates doing nothing, the LED circuit was added to give a visual indication that the clock and all dividers are working. There is a definite pulsating of the LED, so the user is sure that the circuit is working.

The accuracy of the instrument is very dependent upon the tolerance of the calibration capacitor, C3. Prior to use, C3 is switched into the circuit and the frequency of IC1 is adjusted by R2 until the meter reading is equal to the value of C3. The drawing shows C3 as being 5100 pF, 1% tolerance. Actually, any convenient value could be used, but the tap on the range switch would have to be changed to make sure the correct frequency is being applied through C3.

The condition of the battery can be checked by pressing S3. When making a battery test, ensure that there isn't a signal path through a capacitor to the meter, as this would give a higher battery voltage reading than really exists. The multiplier resistor will give a reading of .9 on a full scale of 1.

Construction

I like sockets. It makes troubleshooting easier if a chip must be removed, but sockets are not necessary. All 74LS90s are wired the same as IC2. The range switch is wired to make 5 ranges available. The additional position is used as the calibrate position. A separate switch can be used for calibration, but the user has the chance of damaging his meter if the calibration capacitor is a .005 and the range switch is in the 0-to-100 range position. The ICs can be replaced by 7490s and 7400s,

but the current drain is rather high for a 9-volt battery. If a power supply is used, there is no problem using the TTL chips. The meter rectifiers are run-of-the-mill diodes. The meter is a 50 uA meter with a 0-to-1 scale marked off in .1 readings.

Use

Prior to use, the meter should be calibrated to compensate for those variables that cause errors. After calibration, the unknown capacitor is placed across the test terminals and read. A word of caution is offered: Use this meter as you would a voltmeter in a strange circuit. Start on the high range and work down until you get a reading. This prevents pegging the meter and possibly damaging it.

This circuit is easy to construct and use and should give many years of reliable use. ■

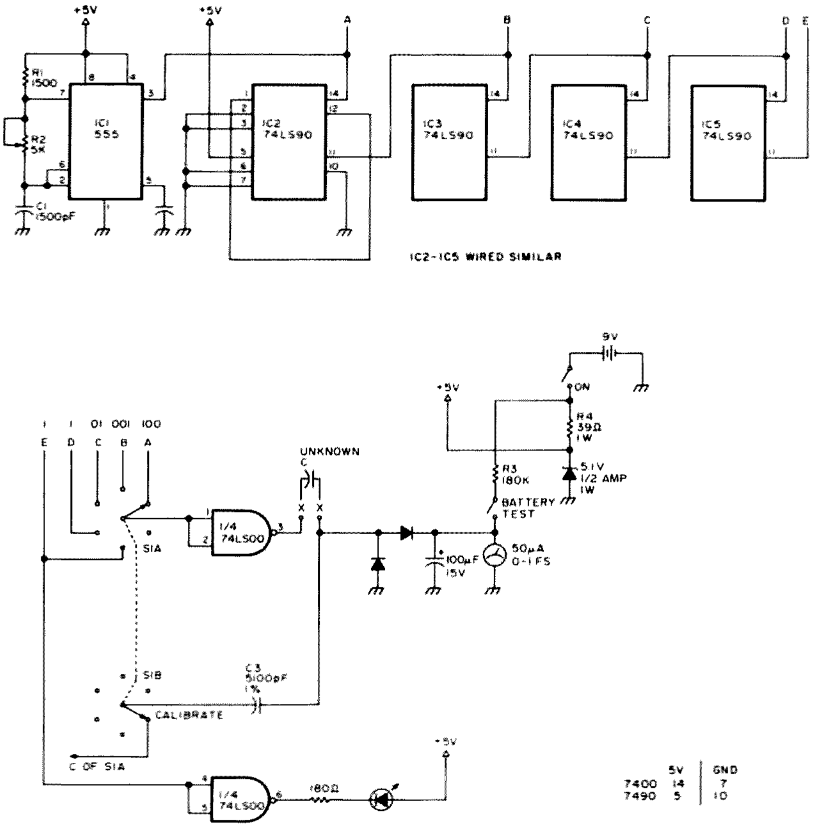

Fig. 1. All resistors are ¼ Watt except as noted.

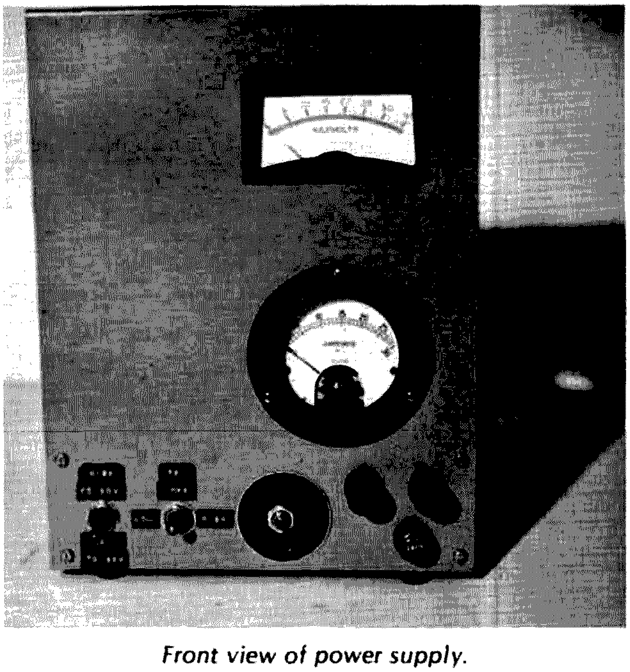
Power Plus!

—a 20-Amp, adjustable, regulated dc supply

Versatility personified.

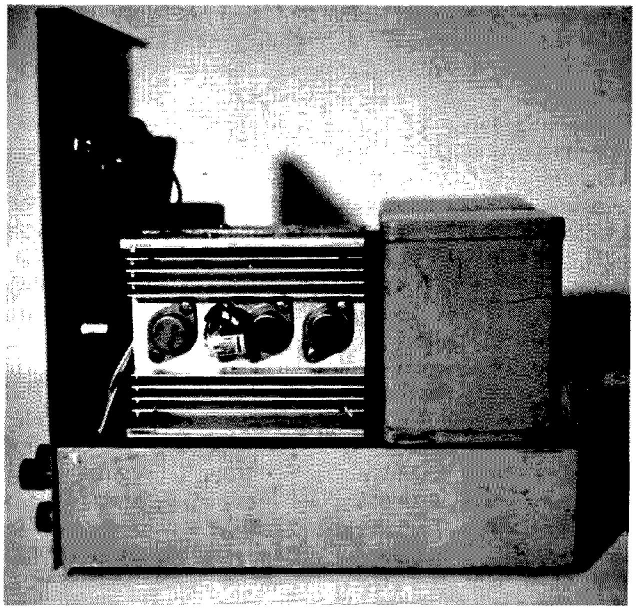
What do you do for a base station regulated power supply after you discover that the amplifier you have just completed requires half again the current you anticipated? The supply described by George Schreyer WB6TOX in the December, 1972, *73 Magazine* is the heftiest I can recall to date described in either *73* or *Ham Radio* magazine. It will supply the 10 Amps as described. I built it with extra heavy-duty components, but could not get acceptable regulation beyond this level. My amplifier requires 17 Amps. After many modifications, many burned-out transistors, and much frustration in attempts not only to increase the current capability but to retain regulation, it was back to the proverbial drawing board.



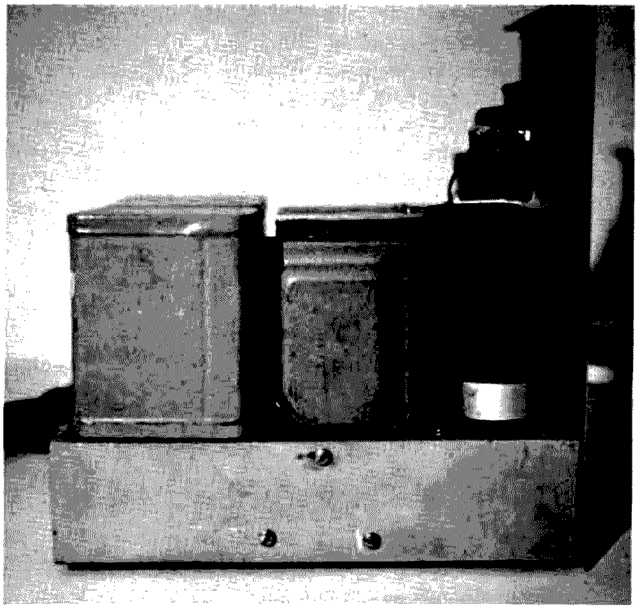
Front view of power supply.

This, then, is an article meant to furnish information that you can add to your pet circuit notebook as well as to provide a circuit and construction ideas for the vast number of hams obtaining bigger and bigger solid state amplifiers. This supply is versatile in that one has a reasonable amount of control over the heat dissipation of the pass transistors despite the amplitude of voltage to be controlled.

Two paralleled power transistors are used as pass transistors; the 2N3772 and 2N3773 might be described as extra-heavy-duty 2N3055s. I use this as a comparison because the 2N3055 is the well-known workhorse. The 3772 and 3773 can dissipate 150 Watts, as compared to the 3055's 115-Watt capacity. These transistors can effectively control voltage amplitudes as low as 1.4 volts. Each 3772 can very safely handle currents to 15 Amperes. The 3773 handles 10 Amperes, again as com-



Left side view of power supply.



Right side view of power supply.

pared to the 3055's 5-Ampere safe capacity. These currents must, of course, be kept within the power dissipation capability of the unit. One would not, for example, attempt to drop 30 volts across a 3772 while pulling 15 Amperes, as this is a 450-Watt dissipation and the transistor has a rating of 150 Watts. Using two of these in parallel, the dissipation capability is increased to 300 Watts. (Even 300 Watts takes a lot of heat sinking to dissipate the heat.)

Refer to the schematic in Fig. 1. Let's examine some practical extremes. Say we wish to regulate 13.0 volts at 20 Amperes, and the input voltage (at the choke output) into the regulators, using the full secondary, is 35 volts; this would result in a drop of 22 volts across the regulators. 22 volts × 20 Amperes = 440 Watts. Obviously, things would start to melt after a very short operating period. Therefore, switches S1 and S2 have been incorporated so that one can obtain the required voltage and current and hold the dissipation within reasonable levels. Thus, setting S2 in the low position, we are only using ¾ of the secondary, or 22.5 V ac, possibly delivering 25 volts (loaded) to the pass transistors. 25 less 13 = 12 volts across the pass transistors, or a total of 240 Watts.

Following this same reasoning, it is apparent that the higher the regulated output voltage, the smaller the voltage drop across the pass transistors and the smaller the power dissipation.

Note that, when using multiple secondary transformers, one has the capability of choosing the appropriate voltages. The switching arrangement shown is the one I use. It may be convenient for some applications to tap the secondaries at other points, i.e., tapping at the 15-volt ac position will result in approximately a 60-Watt dissipation for the above stated example.

Selecting Components

The transformers I used were purchased from army surplus (WW II). They are hermetically sealed units and have an operating ceiling of 60,000 ft. The continuous operating current is called out as 10 Amperes. I have used the supply for over an hour of continuous service at 17 Amperes and the cases stayed at room temperature. The transformers each have two 7.5-volt secondaries. As can be seen in the schematic diagram, I use the windings in series and parallel configurations. The choke possibly can be eliminated with somewhat higher peak voltages being present. Any possible increase in ripple voltage will be smoothed out by the gain in the regulator chip. The

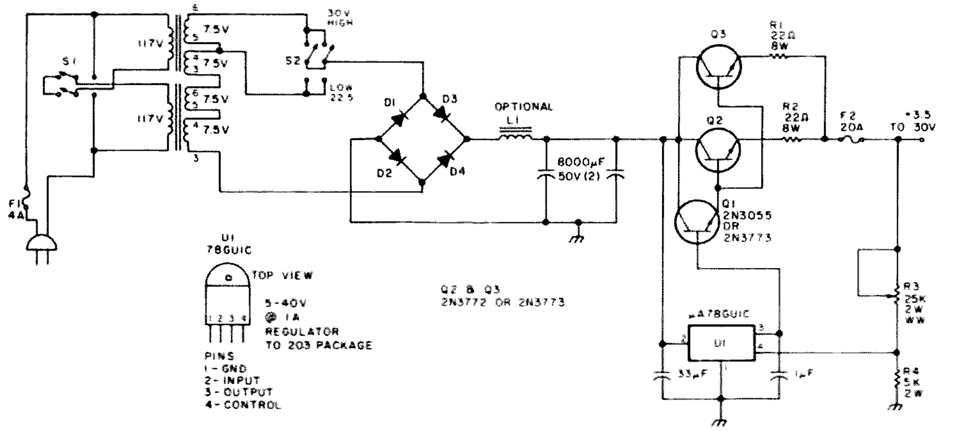


Fig. 1. 17-Ampere super-regulated low-voltage universal power supply —3.5-30.0 volts. S1 and S2—10 Amp contacts @ 120 V; D1-D4—50 V, 30 Amp or equivalent; Q2 and Q3—2N3772 or 2N3773; Q1—2N3055 or 2N3773; U1—µA78GUIC; R1 and R2—paralleled .44 Ω, 4 Watt or equivalent; R3—2.0 Watt, 20k to 25k wire-wound pot; R4—5k, 2 W.

choke was used in a previous unregulated power supply built on this same chassis; therefore, it was retained rather than removed. This choke was built from a Triad filament transformer I had on hand.

Originally, the transformer had four 6.3 V ac 4-Amp windings. The transformer was disassembled, the secondary winding removed, and about 3 or 4 layers of no. 10 or 12 wire wound onto the core. The laminations were reinserted with all of the "E"s in one direction and the "I"s placed at the end.

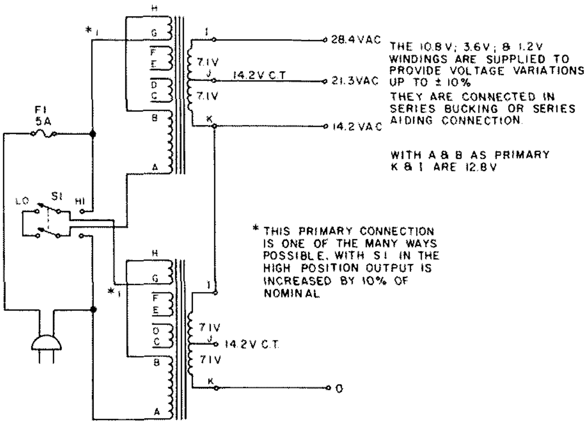

Fig. 2. ITC transformer, part #BP-6242, size 4.5" x 5.0" x 7.0", hermetically sealed, conservatively rated at 20.0 Amperes continuous operation. A pair of these can be substituted for the transformers in the text and offer even more versatility. They are available for $19.50 each from Hiway Company, 305 W. Wisconsin Ave., Oceanside CA 92054.

The regulator chip, a Fairchild uA78GUIC, is the whole key to the success of regulation. It drives a 2N3772; a 2N3773 or even a 2N3055 will work equally well. The rectifiers are 1N3209s, 100-volt, 15-Amp units. They happened to be something I had in my junk box—suitable substitutions can be used. Incidentally, they ran cool at 17 Amps; the heat sinks were cut from heavy aluminum heat sink rails. Two heat sinks were used side by side and isolated from each other, one section for the rectifiers, the other for the pass transistors. For better dissipation, the radiator fins should be vertical. However I have had no problems mounting them horizontally.

Refer to the schematic. The divider composed of R3 and R4 only requires about 1.0 mA of current as the control current to the regulator is only 5 to 8 μA under worst-case conditions. The control voltage is 5.0 volts. The fixed values for a given voltage output at pin 3 can be calculated from the formula Vout = [(R3 + R4)/R4] V, where V control on the 78GUIC = 5 V.

There you have it. Modify as you wish or duplicate as close as possible. The ideas are all there and the supply regulation is super, dropping about 2.0% at any setting up to 24 volts, no load to full load.■

Reaching for the Top

—why stop with the General ticket?

Get that higher class ticket now—and avoid trouble later.

Paul Kalkstein N1PL
Phillips Academy
Andover MA 01810

Amateur radio is in a period of flux these days. Of course, the solar flux index is increasing, a happy sign for propagation, but so is what we might call the regulatory flux index, which comes, not from "Old Sol," but from the puzzling FCC.

Detailed monthly in the pages of *73*, we find many changes in the rules by which our hobby is run. Logging requirements, repeater deregulation, and callsign assignments are examples of significant changes that the FCC has recently wrought. WARC '79, looming directly ahead, poses additional threats to the stability of amateur radio.

Although the future is clouded, some reasons for obtaining an amateur license above the Novice class now, or upgrading to a higher class, are clear. One reason is the very uncertainty of the present. Like the regulations, the amateur examinations are changing. Already in effect are two important changes in the code test.

First, the sending test has been eliminated (except for the Novice); that's one less thing to worry about. Second, the receiving test is not what it used to be. No longer is the subject matter strange stuff about farm statistics in Hawaii or specifications for Coast Guard installations. Now what you are asked to copy at 5, 13, or 20 wpm is one side of a typical amateur QSO. This makes for familiarity and a degree of comfort.

However, instead of copying clear, machine-sent code through headphones, as you may have done before, now you may have to copy from a cassette recorder. There might not be any headphones, and both room acoustics and outside noises may interfere. Adjust your practice accordingly.

You needn't copy one minute correctly any more; in fact, you can just take notes if you want. The examiner measures your comprehension by ten multiple choice questions; you must answer eight correctly. The questions are not tricky, but do thoroughly test whether or not you are able to copy the passage. Hams who have taken both the old and new kinds of code tests loudly praise the new one.

The FCC has indicated that it plans to change the written exam, too. Last year, it issued a new set of study questions. The new test may be easier, and may (like the new Novice tests) be harder. Take the old one if you still can.

If you are going for the Extra class, be advised that the 1 × 2 calls are running out. The new 2 × 1 calls will go fast, so get in there while there is still something left!

Comfort and Confidence

The two parts of an amateur exam, theory and code, vary in kind. You should study for them in different ways, but your goal should be the same for each part—comfort.

Comfort and ease come with mastery of the subject matter. Comfort in turn produces confidence, and confidence is the only weapon you have against that steely-eyed examiner (while others have praised the humanity of certain examiners, I found very little warmth in the last field office I visited).

Comfort and confidence come only with good hard work. You must invest some time—for most of us, quite a lot of time—in learning the code and theory for your test.

Of course, there is another way. For as long as the FCC has been giving exams, there have been peo-

ple who have taken them in much the same spirit that animates the buyer of a lottery ticket: "Maybe I'll be lucky!" The person who thinks this way bolsters himself by studying a cram course or memorizing the answers in the old (not the new) ARRL *License Manual*. He copies a few W1AW code runs and then blithely strolls into the examination room to take his chances.

Very likely we'll see him in the same spot next month, and the following, but after awhile, it will work: Through practice, he'll finally pass. However, by this time he would have been better off doing it the right way from the start, thus gaining some useful knowledge to go with that new ticket.

Study Hard

So, study hard. But it shouldn't be purely a grind. After all, ham radio is a hobby, meant for enjoyment. Your enjoyment should increase as you learn about your hobby. You will not have to mumble when someone starts a modest technical discussion on 75 meters. The process of learning how a radio works should interest you, unless ham radio for you is simply the propagation of your ego across long distances.

Perhaps a class can help you learn more code and theory. More and more clubs are sponsoring classes, not only for prospective Novices, but also for those who want to upgrade. "Ham Help" in *73* or the ARRL can help you find a class.

If you are going for your Extra, or there is no class in your area at the needed time, you may have to go it alone—but don't despair. If you have the right materials, you can learn at least as efficiently on your own as you can in a class, which may move at the speed of the slowest learners. As you work by yourself, you should push yourself hard, but don't go so fast that you fail to learn.

If you, like me, have trouble with the math, check out the series "FCC Math" by WB6CKN, which began in the November, 1977, *73*. It will help.

Learning the Theory

There are two exceptionally useful books to help you learn the theory. One is the new ARRL *License Manual* (the one with the smiling faces on the cover). This has been wholly revised, and is now clearly written and sensibly organized. It follows the study questions released by the FCC. It also contains sample tests to check your knowledge. These tests are as difficult as the actual FCC exam, and therefore provide a pretty good measurement.

The ARRL *Manual* is *not* enough by itself, however. To get beyond the memorization of cloudy "facts" to a real understanding of radio theory, you need a book that goes more deeply into things.

The best of these books are the study guides (Novice class through Extra) which are available from *73*. These originally appeared serially in this magazine, and have helped many amateurs understand radio as they prepared for their tests.

If you are studying for the General class, you can use the *General Class Study Guide*. It is simply written and does a fine job of explaining basic electronic and radio principles to a layman.

But you might consider setting your sights a bit higher. Even if you think you're just General "material," buy the *Advanced Class Study Guide*.

I admit to a special bias toward this book. As a Novice who in real life was a high school English teacher, I saw myself as an anomaly in the ham ranks. I had no training in electronics and was poor at math. I despaired of going higher. On the other hand, my code speed was increasing slowly, and I certainly wanted that higher-grade license. I decided to try for the General.

On the advice of a friend, I bought the *Advanced* guide. Surprisingly, I found it easy to read, even pleasant. Moreover, I found that with some effort I could understand everything in it. What had seemed arcane and unattainable was now within my grasp. When I thought I had it down pretty well, I went into the FCC office in Philadelphia and passed both the General and the Advanced on the first try. Since this method worked so well, I later did the same for the Extra.

The *Extra Class Study Guide* is a superb piece of work. It tells you much more than you need to know for the test, but does it so clearly that you might as well learn it. It is very interesting: Haven't you wondered how TV really works, for instance?

Understanding the material in the *Extra* guide was so confidence-inspiring that I decided to warm up for the Extra exam by trying the commercial radiotelephone tests. I did some cramming on commercial regulations and on a few old concepts like electric motors (which are not covered in the *Extra* guide), using a question-and-answer manual. I passed the Third Class 'Phone easily, and then passed the 100-question Second 'Phone test, but failed the First 'Phone (my third test of the day) by one question.

I don't know what a mild-mannered English teacher will do with a commercial Second 'Phone ticket, but I mention it because it shows the level of preparation provided by the *Extra* guide. The Second 'Phone was much harder than the Extra exam, which I passed with confidence the next day.

Early to Bed

Cultivate regular habits as you study. Set aside a certain time to work. The best time to do this is early in the morning. Ideally, you should study as soon as you are properly awake, a time that varies for all of us. But of course there are other demands made on your time, perhaps by work, children, or school.

Try getting up an hour earlier than usual. Do some exercises. Maybe you will become healthy—a side effect not to be scorned. Then, study for 45 minutes or so.

The material you studied will travel around with you all day. Think about it. Jot down the things that are not clear. Ask yourself questions. At the end of the day, spend half an hour reviewing what you read that morning.

If you can't possibly study in the morning, do it when you can. But the brain becomes weary as the day wears on; learning becomes less efficient. At any rate, study some each day.

Try to put off taking the sample tests until you think you have really mastered the material. If you take them too soon, or too often, your studying will subconsciously aim at answering specific questions on the sample test, and you may miss things that will later appear on the real thing.

Learning the Code

Many articles have appeared on learning the code, and I won't go far into this. One recent article I can recommend is the one

by K6DZY in the October, 1977, 73. The point made there by Boyd is that International Morse Code is a language, and it is learned much as any foreign language is learned. Learning a new language demands exposure (listening) and practice (sending).

The great enemy in learning the code, or improving your speed, is anticipation: guessing what will be sent next. Anticipation causes errors. As speed increases, anticipation causes general confusion and lack of confidence, both of which are destructive to learning.

The way to beat anticipation is to learn to "copy behind." This puts a premium on listening before you write—you are always looking back at what was sent, not ahead at what might be sent.

In his article, Boyd mentions an acquaintance who copied 20 to 30 words behind! If you are trying for 13 wpm, or even 20, copying from one to three letters behind is usually enough. You will be able to recognize words and common prefixes and suffixes, and by concentrating on copying behind, you will prevent anticipation and also be able to correct minor errors.

Learn to copy behind by practicing with cipher groups, or randomly-sent letters, numbers, and punctuation. Wayne Green has made a series of tapes which give practice in this sort of copying. While some of the groups, particularly in the 20+ wpm tape, show evidences of extreme sadism, they are the best tool there is.

This sort of tape has three advantages over other methods of code practice. First, they prevent anticipation by their random nature, and with practice you will get totally out of the anticipation habit. Second, because they are random, you will not find yourself memorizing words in sequence, as you would do if you practiced with plain language tapes. (If you find you have memorized Wayne's tape, it's time for the test. You've mastered the tape, and you'll be able to handle the FCC code with ease.) Third, they are recorded at speeds faster than those required for the FCC test.

To improve at the code, you have to push yourself to a speed which is beyond what you can comfortably copy. Don't be discouraged if you copy very little of the practice tape at first. Begin by listening, and then practice copying what you can, always copying behind. You'll improve, and eventually you'll copy it all. I promise.

Practice the code regularly each day. It needn't take too much time. Half an hour of random groups, divided into four sessions at different times of the day, is plenty. Unlike theory, code can profitably be practiced at night. You'll get a good check of your speed under pressure, with your fatigue approximating your nervousness at an FCC exam. And maybe those "dits" and "dahs" will chase themselves around your subconscious all night.

Slow and Sure

Don't try to rush things. Give yourself all the time you need to study the theory and the code. It may take some time, but keep calm and determined. Remember, if you do it right, you won't miss. If you go into that exam with confidence, you'll walk out with a well-deserved "Interim XX" ticket, and the satisfaction of knowing that you've done a difficult thing well. Good luck! ■

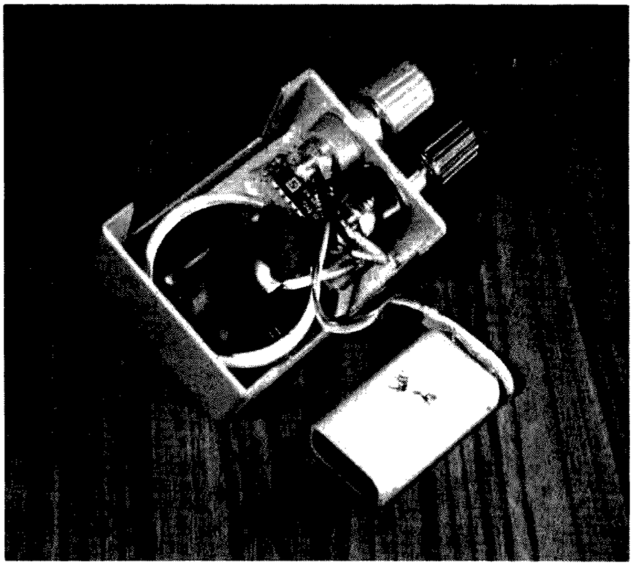
Universal Alarm Circuit

—detects heat, light, moisture . . . you name it

Build your favorite sunbather the ultimate in beach accessories.

Water shortages are not infrequent occurrences in a number of large cities around the world. Tourists get caught off guard sometimes, but residents have learned to cope by immediately filling reserve containers when that first trickle of water reappears after an outage.

The unit described in this article was designed by a staff member while overseas to help the XYL with the water problem by providing an early warning when the water was back again. But, the unit might be more seriously described as a universal alarm circuit. It can be used for a multitude of alarm purposes around the shack by the use of the proper sensor to activate the alarm. A number of such uses are covered here. To turn to the lighter side of things, sunbathers can also use the unit to warn themselves that the tide is coming in and that they are about to be engulfed.



The tester assembles very compactly in a 2" x 3" x 1¾" enclosure. The IC and transistor are under the binding posts and the "speaker" is a 600-Ohm telephone receiver.

The basic circuit shown in Fig. 1 is relatively simple, but yet it has a number of significant advantages:

1. The standby current is less than 10 microamperes! This amount of current is so insignificant that no on-off switch is necessary, and the battery will last for about its shelf life while the circuit is in standby. About 60 mA is drawn from the battery when the alarm operates.

2. The input circuit is quite sensitive, but yet not touchy. For instance, in the water-alarm setup, the "probes" need only be two ordinary pieces of hookup wire. No elaborate interleaving pattern of conductors is required. The probes or sensors can be remotely located from the alarm over considerable distances—50 to 100 feet in many applications.

3. The alarm sounds off when it "sees" less than approximately 120k Ohms at its input terminals. The value of this resistance will vary a bit from alarm to alarm because of the tolerance of the components used for circuit construction. But, for any given alarm constructed, it will have a definite value that will remain constant over wide extremes of temperature. So any sensor can be used with the alarm that provides any resistance less than 120k Ohms when the alarm is to sound.

The heart of the circuit of Fig. 1 is the CD4001 quad NOR gate. The last two gates act as a multivibrator that is turned on when pin 8 goes low. The second gate is an inverter, and the first gate acts as an input stage. Normally, pin 3 is low and pin 4 is high. Activation of the first stage reverses this condition, and the multivibrator operates. The 2N1375 stage provides a bit of high-distortion amplification to drive a 600-Ohm telephone-type receiver unit to a very penetrating output level. A small speaker can be used

instead, but then one has to experiment with some series resistance in the 2N1375 collector lead to limit the current. With the usual 4- to 8-Ohm speaker, something on the order of 47 to 220 Ohms should suffice.

The multivibrator frequency is a function of the 10k and 22k resistors and the .01 uF capacitor. A frequency of about 3,000 Hz appears to be produced, although it is difficult to tell because of the high distortion which makes it sound so penetrating. At any rate, one can scale these RC values up or down so different output frequencies are produced to allow sensing which alarm went off if a multiple alarm setup is used. In addition, one could place an LED or relay in the 2N1375 collector lead to activate a visual alarm.

As was mentioned before, any sensor which provides less than about 120k resistance can be used. Thermistors and photocells would be typical examples for temperature and light sensing. A series resistor can be added to the sensor circuit, so the alarm is activated at the desired point. The unit will function directly as a diode and transistor junction tester and, also, as a crude but effective ohmmeter to check relays, switches, etc.

Voltage and current sensing can be done by simple transistor switch circuits, such as shown in Fig. 2. When the transistor turns on, the alarm circuit will be activated. So one can build a variety of alarms which check for any over-limit condition (excessive swr, line voltage, modulation, etc.) by just sensing any dc voltage available in a transceiver or swr bridge which increases as the function desired to be monitored increases in amplitude. By choosing the resistance values carefully in Fig. 2, very little loading will be presented to the circuit being monitored.

How about checking for under-limit conditions, such as low temperatures, low battery voltage, etc.? All of the foregoing applies. Just bypass the second gate in the CD4001. The alarm will now activate when any sensor presents a resistance which goes above about 120k Ohms. The same outstanding feature of the alarm circuit applies in this mode in that practically no current is drawn from the alarm battery supply until it is actually activated.■

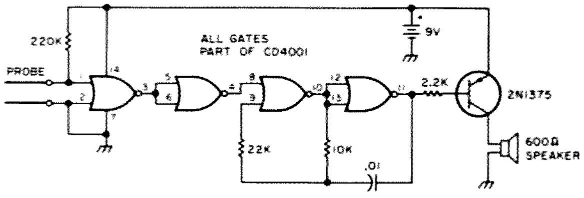


Fig. 1. One IC and one transistor make up a sensitive and loud alarm circuit.

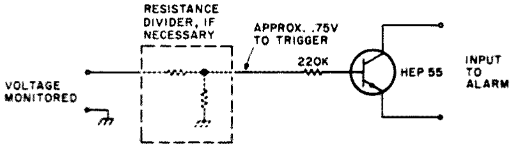

Fig. 2. Simple transistor switch addition allows alarm to monitor a wide variety of circuits for over- or under-limit conditions.

Exorcise Those Unwanted Frequencies

—try coaxial stub filters

Put your problems to rest.

There are times when one might run into the problem of a specific spurious frequency being radiated by a transmitter and causing interference problems, or reception problems caused by a specific undesired signal. The usual approaches to these problems are various types of LC traps, filters, etc. However, there is another approach which is often very useful as well as economical. No involved construction of tuned circuits is necessary, and one can achieve 30 dB or more suppression of an undesired frequency in either the transmitting or receiving mode.

The basic idea of coaxial stub filters is very simple. As shown in Fig. 1, a section of transmission line which is ½λ-long and which is shorted at one end will reflect an electrical short to the other mechanically-open end of the transmission line. This will only occur at the frequency for which the transmission line is ½λ-long. So, if we have a transmission line going to a transmitter or receiver as in Fig. 2(a), and wish to suppress some frequency, we can insert a ½λ-long rejection stub for the frequency to be attenuated. At that frequency, the coaxial transmission line to the receiver or transmitter will electrically act as if it were shorted. Although there are some cases where only a rejection stub can be used, usually it has to be combined with a correction stub as shown in Fig. 2(b). This is because the rejection stub at the desired operating frequency will present some reactance across the main transmission line. The correction stub cancels this undesired reactance so that at the operating frequency the main transmission line acts electrically as though there were no stubs at all on it.

That is all there is to the theory of a coaxial stub filter. The rest of this article is mainly concerned with the practical aspects of determining the lengths of the stubs and special applications. The stub filter idea can be used over a very wide frequency range. The limitations to its application are mainly mechanical, in that at very low frequencies the rejection stub may become too long, and at UHF frequencies it may not be possible to dimension the stubs accurately enough. As was mentioned before, the rejection stub has to be ½λ-long at the frequency attenuated. The ½λ length must be an electrical length, so when you're dealing with coaxial cable it will differ from the physical length because of the velocity factor of the cable. Fig. 3 presents the actual physical length that a coaxial stub should have in order to be electrically ½λ-long at a given frequency. The graph is based on a velocity factor of 0.66, which is the usual one for all common coaxial cables (RG-8, -58, -59, etc.). The graph only covers the frequency range from 10 to 150 MHz, but one can calculate the length of coaxial stub needed at any other frequency from the formula:

$$\text{Length (inches)} = \frac{3897}{F\ (\text{MHz})}$$

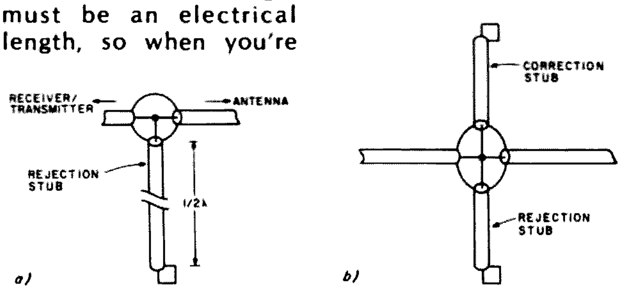

Fig. 2. Placement of rejection stub (a) and rejection stub with correction stub (b). The ends of both stubs are shorted. Although for clarity the shields are shown connected together by jumpers, they should, in reality, be directly soldered or otherwise connected together.

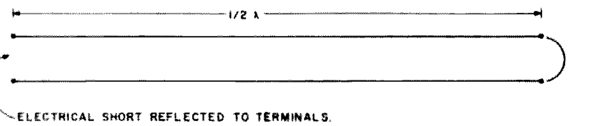

Fig. 1. Stub filters are based on characteristics of a ½λ transmission line.

Remember that the frequency involved in this case is the undesired one which one wishes to attenuate, and not the operating frequency.

In practice, one should cut the piece of coaxial cable several inches longer than called for to allow for pruning. Install the rejection stub reasonably close to the antenna terminals of the transmitter or receiver being used. Various types of coaxial connectors are available to interconnect the lines, but the interconnections can simply be soldered on without connectors for indoor usage. Using a pin or pick, short-circuit the outer shield of the rejection stub to the inner conductor at various points starting from the outer end of the stub until maximum attenuation of the undesired signal is achieved. When the best point is found, cut off the excess cable, fold the outer shield around the inner conductor, and solder them together.

The length of the correction stub will vary from zero to ½λ. Its length can be determined approximately from the graph of Fig. 4. In this case, by knowing the ratio of the undesired frequency to the operating frequency, one can determine the electrical length of the correction stub at the *operating* frequency. The physical length of the coaxial cable used can be determined from the formula previously given for a ½λ-length stub. As in the case of the rejection stub, the correction stub should initially be made longer than calculated. The correction stub is then experimentally shorted until the least attenuation is produced at the operating frequency. If a transmitter is being used, the correct stub length is easily determined by pruning the stub until an swr meter indicates a flat line.

As an example of the foregoing, say we were operating on 21 MHz but had problems with an interfering signal on 26 MHz (in the transmitting case, our operation on 21 MHz was producing some spurious radiation on 26 MHz). The length of the 26-MHz rejection stub would be approximately 150 inches. 26 MHz is about 1.25 F on the graph of Fig. 4, so the approximate length of the correction stub is 1/16λ at 21 MHz, or about 23 inches.

All of the foregoing may seem like a bit of work, but really all it takes is patience and a slight amount of math. The results that can be achieved by the simple application of stub filters are shown in Fig. 5. Those are not bad results for just the cost of lengths of coaxial cable.

There are several special cases that one should be aware of. If the frequency which is to be attenuated is 1/8, 1/4, or 1/2 of the operating frequency, the idea of coaxial stub filters will not work. This is because the rejection stub will turn out to be a wavelength or a multiple thereof at the operating frequency. Therefore, it will present an electrical short across the transmission line also at the operating frequency. Note that the graph of Fig. 4 is broken at several points, e.g., .75 F and 2 F. In these cases, the indicated length of the rejection stub would be ¼λ at the operating frequency. But, a shorted ¼λ stub represents an open circuit, so there is no need for the correction stub at all in these cases. The 2 F case is interesting, of course, since it would represent the second harmonic of a transmitter. By using only a rejection stub, therefore, one could get a nice bit of additional second harmonic attenuation. In fact, it will attenuate all even harmonics.

One can use more than one stub filter or different stub filters on various bands with a switching arrangement. Many combinations are possible, and in some cases only the correction stub may have to be switched on different bands. As a bonus feature of the stub filter idea, note that the shorted end of the rejection stub can be grounded if desired. Thus, one can provide a direct electrical connection to ground for lightning protection, static drain, etc., for an antenna system that does not have to be switched in or out when operating. In a multiple antenna system, one could have a grounded stub for each antenna so that each antenna is continuously protected. ■

10¢ Mod for the 22S

—extra channels for $.00455 each

Have you heard of an easier way?

By now you've probably heard of at least a dozen ways to increase the channel capacity of your Icom IC-22S. When we bought ours, we wanted expanded frequency coverage, but we also wanted coverage of all common repeater frequencies, no added switches or complicated gadgets, a system that could be used while driving, and a minimal investment of time, money, and energy.

Channel	Frequency*	
1.	146.01	146.04
2.	.07	.10
3.	.13	.16
4.	.19	.22
5.	.25	.28
6.	.31	.34
7.	.37	.40
8.	146.97	147.00
9.	147.03	.06

*Table 1. *The matrix may be programmed for the frequencies shown in the first column. These frequencies will be obtained in the simplex mode with the power switch on low, and the frequencies in the second column will be obtained with the power switch on high.*

Now that everyone else has had his turn, here is the lazy man's approach to the problem. All it takes to convert your IC-22S to an "IC-44S" is a soldering iron, a ten-cent diode, and a spare hour or two. The only drawback to this scheme is that you must confine yourself to high-power operation only. Since our QTH has all the propagation characteristics of a black hole, this was an easy trade-off to make.

The basic principle of our modification is identical to that described by Don Jenkins WA6OAZ in the January, 1977, issue of *73*. The matrix is programmed for frequencies separated by 60 kHz, and a diode is switched into the matrix to increase the programmed frequency by 30 kHz when so desired. The difference is that the need for external switching is eliminated by using one-half of the power switch. Operation is straightforward: When the power switch is in the low position, the base frequency is the programmed frequency, and when the power switch is in the high position, the base frequency is the programmed frequency plus 30 kHz.

The first step in modifying the circuitry is to free the half of the power switch that controls the output level and to wire the circuit board for high-power operation. One side of this DPDT switch is used to supply 13.8 V dc to the rig in both the high and low power modes. From the other side of the switch, three wires lead to the main circuit board below the synthesizer board. Because of the tight location of the power switch, it is much easier to remove the synthesizer board and

access these wires as they connect to the main board than it would be to unsolder them from the switch. This is easily done by removing the matrix board and the three screws and one threaded spacer that hold the synthesizer board and an underlying metal tray. With the synthesizer board set aside, find the brown wire leading from the center position of the lateral half of the power switch to the main circuit board at a point marked W15 on the foil. This point is in the right rear corner as the rig lies inverted and is viewed from the front. Next find the purple wire leading from the switch contact nearest the synthesizer board and the side of the rig to the main board at point W-16. Cut the brown wire so that the segment extending from point W-15 is just long enough to connect to the foil at point W-16. Unsolder the purple wire from the foil and solder the brown wire from point W-15 in its place. Now find the pink wire leading from the switch contact nearest the true top and the side of the rig to the main board at point W-17. Cut this wire at the foil and tape the end, as it will not be used. Now you should have a connection between points W-15 and W-16, two wires leading from the power switch that are shorted together when the switch is in the high position, and a third wire from the switch that is not used. Replace the metal tray and the synthesizer board, but leave the matrix board free.

The next step is to add one diode to the matrix board in the D1 file and to connect it so that 9 V dc is applied across it with the power switch in the high position. The diode, a 1N4148, 1N914A, or equivalent, is inserted cathode-first from the diode side of the matrix board into a hole in the D1 file in the rank corresponding to channel 1 or 2. Solder the purple wire to the anode of the diode. Connect the brown wire to the matrix board at the point marked 9 V dc. You may need to extend these wires a few inches to reach the matrix board. The circuit modifications are now complete.

The matrix can be reprogrammed for any frequencies as long as diodes are not used in the D1 file (as this would cause redundancy), and all 22 channels must be programmed. Mr. Jenkins points out that if the extra diode is switched into the circuit and the selector passes an unprogrammed channel, the rig will lock onto this blank channel until the power is momentarily switched off. I chose to program my rig in the same fashion as Mr. Jenkins demonstrated, and those channel frequencies are repeated here for any unfortunates having no back issue of *73*. This is only a guideline; you may wish to include 15 kHz split-channel repeater frequencies or your own clandestine frequencies. If you run short of diodes, a trip to Radio Shack with a dollar in hand will get you ten more.

In the time we have used the IC-22S with this modification, we have not heard of an easier way to increase the channel capacity of this versatile rig without drilling holes, adding switches, or constructing things more complex than we dare to try. We can't brag of access to all 133 possible channels, but we rarely need them all anyway. ■

The 10-GHz Cookbook

— monster article

Stick to your Gunns.

John Roos K6IQL
953 Valley High
Thousand Oaks CA 91360

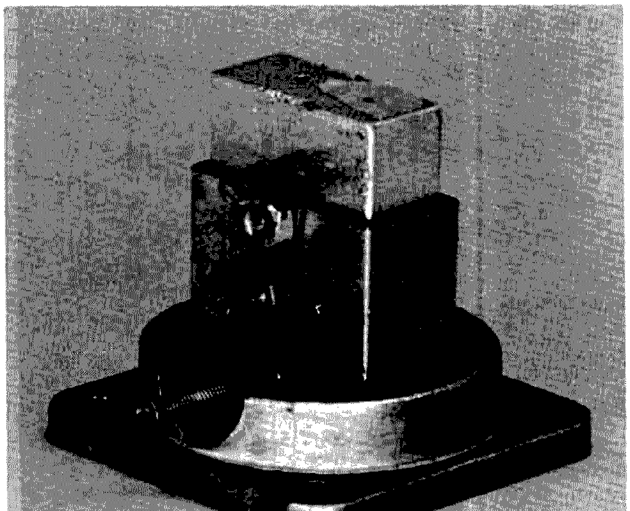

Photo A. The breadboard Gunn-diode oscillator. The waveguide flange is relieved to clear the 2-56 frequency adjustment screw. The positive supply connection is to the turret terminal of the diode mount.

The amateur 10 GHz band offers many fascinating opportunities for both communications and experimentation. Antennas of very high gain are of practical size so that many tens of miles may be spanned with good reliability. The band is a natural for linking of VHF and UHF repeaters, control of repeaters, or control of remote base stations. Activity in the band has been limited by the lack of a good low-cost rf source. A number of transmitters and receivers have been built using surplus klystron tubes, but since surplus items are not generally available to everyone, these designs are difficult to duplicate. In addition, the development of repeater command links or interties requires that the equipment be reliable and compatible with other solid-state gear. Klystron-based designs with the necessary high-voltage dc supplies are certainly not desirable. Gunn-diode oscillators offer an attractive alternative. Properly applied, they will provide up to several hundred milliwatts of stable low-noise rf power.

Gunn-diode technology has been with us for about ten years. In that time, the device has moved from a lab curiosity to a mainstay of microwave engineering. There has always been both commercial and military demand for an inexpensive solid-state microwave rf source. In response to this need, the technology has been pushed rapidly and the price of the diodes has fallen to the point where commercial applications such as radar intrusion alarms, speed meters, and door openers are common. The price of a 10 milliwatt X-band diode is now less than ten dollars. More powerful devices

cost more but are still quite reasonable. Actually, some very practical systems may be built with a 10-milliwatt transmitter. Using a 3-foot dish with 36 dB of gain and a 10-milliwatt source, one obtains an effective radiated power of 40 Watts! That is more than ample for most applications.

My objective in writing this article is to create some interest in X-band operation and to show how easy it is to get started. I will describe the operation of Gunn diodes and present a practical oscillator design. The oscillator tunes the entire 10.0-10.5 GHz band with a power capability of more than 20 milliwatts. The oscillator is easily reproduced and is very reliable. One unit has been operating for almost three years and several others have been built. They all have worked perfectly, so I have a lot of confidence in the design.

This is a new area to many amateurs, so I will describe some tests and trade-offs that may be made to optimize a Gunn-diode oscillator for particular applications. The effects of load mismatch upon the power output and frequency of the oscillator were measured and data was taken for two diode types. I will describe both the tests and the results obtained. Afc or phase locking requires electronic tuning of the oscillator. The frequency of Gunn-diode oscillators may be controlled to a limited extent with the dc supply voltage. I made some tests to determine how useful this can be and will discuss the results. Applications for this design are numerous and my objective is to give as much practical data as possible to aid you in putting the circuit to work in your system.

So much for science! Making a Gunn oscillator is fun only if you can do

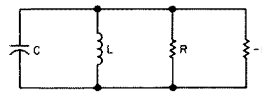

Fig. 1. Negative-resistance oscillator. L and C are the resonant circuit elements. R represents all losses, including output power. The negative resistance of the Gunn diode is represented by −R.

something with it. Part of the article describes a simple transceiver which may be made by adding a mixer to the basic oscillator. This is an ideal device for getting started on the band. It has two immediate uses: as a simple transceiver for communications, and as a Doppler radar. A Doppler-radar processor is included. The processor turns the transceiver into an effective speed meter, door opener, kid watcher, intrusion alarm, or whatever.

The transceiver may be used as a wideband FM link by modulating the dc bias supply and using an FM tuner or receiver as an i-f strip. The basic oscillators are useful as transmitters or as receiver local oscillators in either wideband or narrowband FM systems. Hopefully, someone will use the design as a starting point for an operational repeater command link or other X-band system application.

Gunn Oscillator Operation

Gunn oscillators are negative-resistance oscillators. Fig. 1 is a schematic of a negative-resistance oscillator modeled as a conventional LC oscillator. If the L and C were truly lossless and no power were taken from such a circuit, it would continue to oscillate once started. Real components do have losses and these are lumped into the loss resistance, R, of Fig. 1. Any output power taken from the circuit is also a loss, and that is also

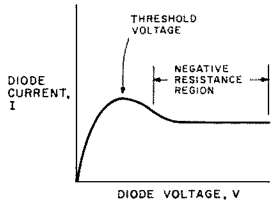

Fig. 2. Gunn-diode voltage-vs.-current plot. Above the threshold voltage, the curve reverses and the current decreases with increasing voltage.

included in R. The effect of a negative resistor is to provide rather than consume power. This is a theoretical concept, but one that can be realized in practice. An LC circuit having more net negative resistance than positive loss resistance will provide sustained oscillations at the resonant frequency of the tank. In practical circuits, the negative R is supplied by tunnel diodes, Gunn diodes, Impatt diodes, and some transistor connections. A Q multiplier is an example of the negative-resistance concept. As the Q is increased, the circuit suddenly breaks into sustained oscillations; more negative R is being introduced into the circuit than there is loss and the circuit takes off.

A Gunn-diode oscillator is simply a microwave cavity resonator to provide the LC circuit and a negative resistance in the form of a Gunn diode.

Gunn diodes are made of gallium arsenide. The GaAs material can have electrons in either of two conduction bands. The electrons in one band happen to have much higher mobility than in the other band. Electron mobility is the measure to the rate of travel of electrons in the material. Greater mobility means higher velocity. In the absence of an applied electric field (voltage across the material), electrons are in the high mobility band. As the voltage across the material is in-

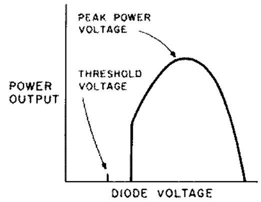

Fig. 3. Gunn-diode oscillator power vs. diode voltage. The peak power voltage will be different at different frequencies.

creased, more move to the low-mobility band. The electron mobility in the material as a whole then becomes the average of the high and low mobilities. This means that the average velocity of an electron drops. Increasing voltage drops the velocity further.

Electric current is the measure of the number of electrons passing a point per second. In positive resistances, the current increases with increasing voltage. In other words, the average electron velocity increases with voltage. In GaAs, the velocity drops with increasing voltage. This means that the current also drops as the voltage is increased and we have a negative resistance.

The electric field intensity where the current begins to decrease is called the threshold field. Fig. 2 shows the current-vs.-voltage curve for a Gunn diode. The current initially rises as the voltage is increased. At the threshold voltage, the curve reverses and the current starts to fall. This occurs at a field intensity of 3200 volts per centimeter in GaAs.

This seems like a lot of voltage, but the active region of the diode is made quite thin and the threshold field occurs at applied voltages of only a few volts in actual diodes. The negative-resistance region occurs just above the threshold voltage, and somewhere above that point oscillations will start.

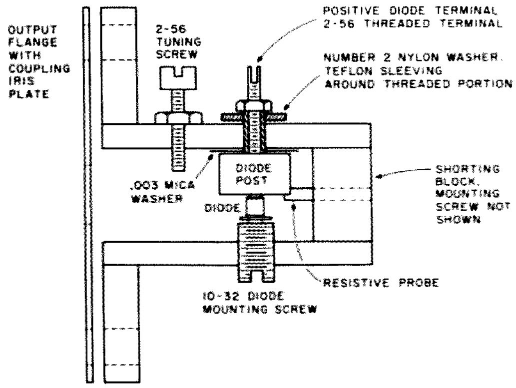

Fig. 4. The Gunn-diode oscillator assembly. Note that the flanged end of the diode (the cathode) is grounded by the diode-mounting screw.

There is one catch. The thickness of the diode must be made to match the travel time of the electrons at the desired frequency of oscillation. This is to ensure that the proper phase relations occur between the electric field and electric current. The diode thickness must be one "transit time length," so that the electron travels the length of the diode in one rf cycle. In other words, the diode thickness must be chosen with the operating frequency in mind, and not any diode will work at any frequency. This is not as bad as it seems. While diodes are characterized at a particular frequency, they will work over ranges of up to two to one.

As explained above, the applied voltage varies the electron velocity. Thus a diode of a given thickness may be voltage-tuned to optimize operation at a particular frequency. In effect, the transit time is changed by adjusting the electron velocity rather than the diode thickness. It is this mechanism which makes the Gunn oscillator tunable with supply voltage.

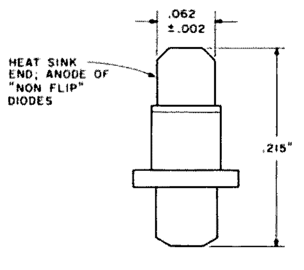

Fig. 5. Gunn-diode package.

Fig. 3 shows the effect of supply voltage upon the power output of the oscillator. At some voltage above the threshold, the electron velocity is appropriate to supply negative resistance to the tank circuit. Oscillations start. As the supply is increased, the optimum transit time velocity is obtained and a point of maximum power output occurs for that frequency. If the tank is tuned to another frequency, a slightly different supply voltage will yield maximum power output. Above the maximum power voltage, the power drops off and oscillations finally cease. A typical low-power X-band diode will have a threshold voltage of 3 or 4 volts and will operate from 6 to 10 volts.

Changing the transit time by adjusting the supply in effect "pushes" the resonant frequency of the tank circuit. The diode wants to make negative R at a different frequency than the tank, but the high Q cavity resonator dominates and only a slight frequency shift is obtained. This is enough to be practical for some afc purposes. Frequency changes of more than 20 MHz can be obtained with a 2-volt supply change. Some amplitude change also occurs, but most FM communications systems or mixer LOs can handle amplitude variations of up to 3 dB with no problem.

Gunn diodes have a problem with low-temperature starting. Both the power peak voltage and starting voltage increase as the diode temperature is lowered. Be sure to operate an oscillator well above the room-temperature starting voltage if low-temperature operation is intended.

Building a successful Gunn oscillator reduces to the essential problems of selection of an appropriate diode and installing it in a suitable resonator. Either coaxial- or waveguide-cavity resonators may be used. Low-stability designs having several GHz of tuning range are generally done in coax cavities. High-stability designs tend to use waveguide because of the higher cavity Q which may be obtained. One major factor in getting an oscillator to work is the suppression of spurious resonances in the cavity. The Gunn device has negative resistance over a wide bandwidth and will oscillate easily at resonances other than the desired one if care if not taken. Resonances in the bias chokes or feedthrough capacitor, higher-order waveguide modes, and coaxial modes involving the diode mount are all possible culprits. An effective cure for some of these problems is the inclusion of a lossy material in the cavity at a point where energy is dissipated only by the undesired resonance. This solution was applied to my oscillator in the form of a piece of pencil lead positioned to absorb energy from a coaxial resonance in the diode mount at 13 GHz. Without the loss material, the oscillator went weakly at 13 GHz and no output was obtained in the amateur band. With the parasitic suppressor present, it always works at the correct frequency and starts easily.

Oscillator Construction

The Gunn oscillator is constructed from standard 1.0" by 0.5" X-band waveguide. The EIA and JAN designations for this guide are WR-90 and RG-52/U respectively. The oscillator cavity is a one-half-wavelength resonator with a circular output-coupling iris. Fig. 4 is a side view of the internal oscillator assembly. The diode is mounted across the narrow dimension of the guide and is parallel with the electric field in the cavity. The diode and its mount effectively short the guide in the plane of the diode-mount centerline. Thus the resonant length of the cavity extends from the center of the diode mount to the plane of the coupling iris. The presence of the iris lowers the resonant frequency of the cavity slightly. To ensure that the band may be tuned, the cavity is made about 10 percent short. The cavity is then tuned to the desired frequency with the 2-56 tuning screw. This is located at a point one-quarter wave from the iris. The electric field intensity is greatest at that point and the screw has the most effect. The cavity tunes the 10.0- to 10.5-GHz band and several hundred MHz above and below with the dimensions given.

Gunn diodes come in a variety of package styles. Most use an internal "flip-chip" construction to make the heat sink the cathode. This permits use of positive-bias supplies with respect to the heat sink. This does, however, increase the package cost.

Low-power diodes can be made in "non-flip" packages provided a means is provided to remove heat from the anode. To do this, an effective but dc-isolated heat sink is required. This oscillator is designed to use "non-flip" diodes while having the desirable feature of a positive power-supply input with respect to waveguide ground. For "non-flip" diodes such as the Alpha type DGB-6844C or Microwave Associates type 49508 used in this oscillator, the anode is the heat-sink end of the package as indicated in Fig. 5. The cathode is the end with the sealing flange. Fig. 4 shows the cathode (flanged) end of the package inserted in the grounded diode-mounting screw. If other diodes are tried in the oscillator, be sure to determine which end of the package is the anode. Remember that unless a diode is designated a "non-flip" type, the cathode will most likely be the heat-sink end of the package.

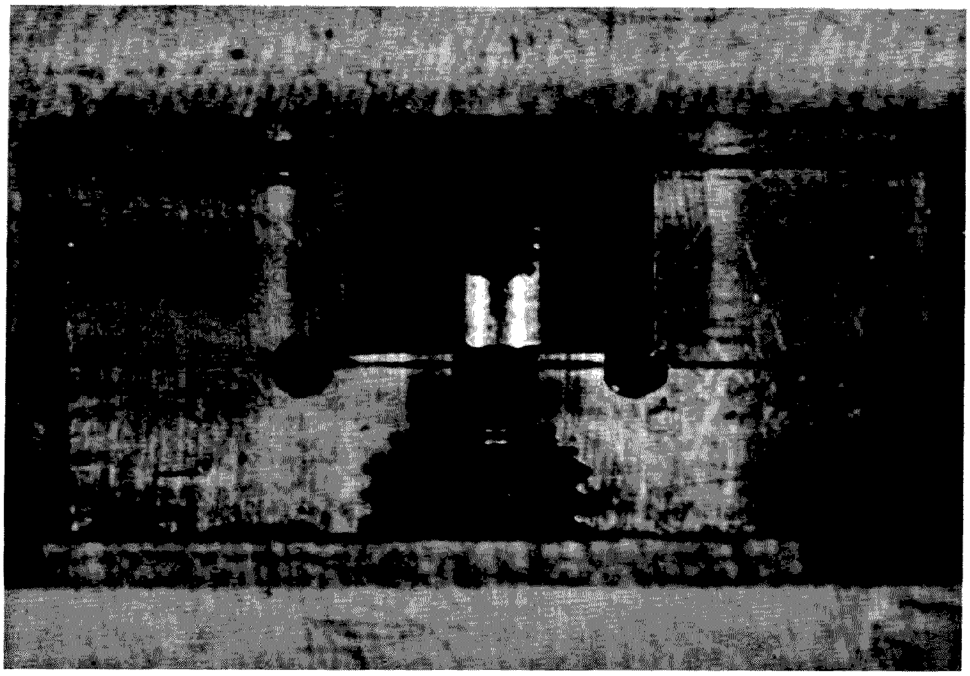

Photo B. Interior view of the oscillator cavity. The Gunn diode is mounted between the heat-sink post and the 10-32 diode-mounting screw. The end of the resistive probe is to the right of the mounting post. The 2-56 frequency adjustment screw protrudes into the cavity from above and in front of the diode-mounting post. The hole in the shorting block to the left of the diode mount is for a trial loss probe location.

Fig. 6(a) is a detailed drawing of the waveguide cavity. The diode mount is installed in holes B and C. Be sure to hold the dimension from these holes to the face of the flange to ensure that the cavity will resonate in the band. There are several varieties of waveguide flange. The intent of the cavity drawing is to use a flange such as a UG-39/U. The waveguide will pass through the flange and should be flush with the face. This will maintain the proper dimension from diode mount to the output iris.

The shorting block, Fig. 6(b), is made from a piece of aluminum. The photo of the breadboard version of the oscillator shows a slightly longer shorting plug. This was to provide a handle for ease of adjustment during the initial design. Make your short as indicated in Fig. 6(b), as it is correct. Hole "E" in the shorting block is for insertion of a resistive probe of common mechanical-pencil lead, as shown in Fig. 4. This is the lossy material which suppresses the undesired spurious oscillation at 13 GHz. An alternative approach to the shorting block is to use a simple plate soldered in the plane of the inner surface of the block. This may be somewhat easier to build, but the probe installation is more difficult. This option applies to the oscillator only. The transceiver version described below requires that the short be removable and the block shown should be used.

The diode mount is shown assembled in Fig. 4 and the detail parts are sketched in Fig. 7. The mount has to do several things at once—match the low diode impedance to the cavity, dissipate heat from the diode, and apply dc bias to the diode while keeping the rf inside the cavity. The heat-sink post, Fig. 7(b), is made from 0.312-inch aluminum rod. It is first drilled through with a number 52 drill to clear the anode end of the diode. This gives a minimum clearance hole diameter for improved heat sinking. It is then drilled at one end only to a depth of 0.100 inch and tapped for a 2-56 thread.

The diode heat-sink post is mounted in the cavity with a 2-56 threaded turret terminal which will be the positive supply connection. Insulation is by means of a nylon washer on the exterior of the guide, Teflon™ sleeving on the threaded portion of the terminal, and a mica sheet insulator between the diode post and the interior wall of the waveguide. The mica forms the insulator of a parallel plate capacitor consisting of the diode post and the interior wall of the waveguide. I used .003-inch mica cut from a TO-3 transistor insulator. The capacitance is more than 20 pF and it is essentially a short circuit at 10 GHz. No rf leakage occurs. A small amount of heat-sink compound should be applied to each surface of the mica insulator. Clean off the excess after assembly as it could cause power loss or frequency drift if left in the cavity.

The 10-32 diode-mounting screw is made from either brass or aluminum. Brass is permissible from a thermal standpoint because most of the heat flow is from the anode end of the diode.

The waveguide output flange is soldered to the output end of the cavity waveguide. Take care that the surface of the flange is flush with the end of the waveguide. Spacing it back will increase the length of the cavity. One caution: Choke-style flanges should not be used on the oscillator. They will not properly clamp the output iris plate and this may change the effective cavity size. Flat

flanges should be used.

The intent of the removable output-coupling iris plate is to permit easy adjustment of the output coupling. Some applications, such as receiver local oscillators, require only a few milliwatts of power. The power may be reduced and stability greatly increased by using a smaller iris.

The iris plates may be made from ten- to forty-thousandths copper or brass sheet. I used 10-thousandths copper sheet. The iris hole is the waveguide centerline. The output hole diameter may be either .290 or .320 inches as discussed in the section on testing. Smaller diameters can be used to reduce power output. If the iris is much larger than .320, the cavity Q becomes very low and the oscillator does not work below 10.5 GHz.

Assembly of the oscillator should be done in the following order. First, solder the output flange to the cavity and remove all flux. Next, install the diode-mounting post as described above. Do not install the diode itself. Install a resistive probe of .040-inch soft pencil lead in the hole in the shorting block. It should extend into the cavity 0.150 inches. It may be held in place by means of tape on the outside surface of the block until the oscillator is tested. After testing, secure the probe with a drop of glue. The shorting block is next inserted into the cavity and fastened with 4-40 hardware. This hardware should be tightened to the final torque prior to installing the diode. If it is tightened after the diode is installed, the resulting deformation of the cavity may break the diode. Now install the diode. Put a tiny amount of heat-sink goo on the diode anode and cathode pins. Remember the heat-sink end goes to the capacitive mounting post. The flanged end is the cathode and goes to ground. Tighten the 10-32 screw so it is just snug. If a lock nut is used, hold the 10-32 screw from rotating while the lock nut is torqued. This will prevent crushing the diode package. The final steps are to install the tuning screw and the output iris. The iris is clamped between the output flange and the flange on the mating waveguide. Start out with the .290-inch-diameter iris. The oscillator is now ready for test.

Operation and Test

Upon completion of the oscillator, it may be put to use in your particular application. My objective in writing this article was to give an easily-reproduced design which could be used for a variety of applications from receiver LOs to simple transmitters. The test equipment to completely characterize a microwave oscillator is not all that complex, but it certainly isn't found at your corner electronics outlet. Some amateurs have access to commercial or surplus test gear which is of great aid in getting started on X-band. Others have only a scope and VOM and will build this oscillator or the transceiver version described later on as a first project in X-band.

In order to ensure that the design was sound and to obtain enough information to help others apply the circuit to their projects, I took a lot of data to characterize the circuit. With this information, the oscillator may be used with some advance knowledge of how it will behave. The description of the tests performed is provided in case others who can get ahold of the gear wish to repeat the tests or test their own oscillator designs, and to indicate to those who will just build the circuit how the data is obtained. Before getting into the rf testing, here are a few cautions with regard to dc power supplies for Gunn oscillators.

Dc power must be applied to Gunn diodes with some care. The negative-resistance effect extends down to dc, as illustrated in Fig. 2. This can cause dc supply regulators to misbehave. Generally, a series-pass regulator gets very confused when decreasing the voltage increases the current being drawn. The regulator may oscillate and overshoot. The Gunn device may well disappear in the ensuing excitement. Fig. 8 shows a safe method of powering the oscillator. A current-limited supply is used. In shunt with the supply is a husky zener diode which limits the maximum voltage which can be applied to the oscillator to a value of a volt or so above the operating voltage. This will prevent burnout on turn-on transients or if the

Minimum and Maximum Power into 2 to 1 vswr vs. frequency

4	100	9-22 mW	9-19 mW	10-25 mW	10-22 mW	10-22 mW	10-22 mW
5	125	9-20 mW	7-21 mW	9-18 mW	12-24 mW	14-25 mW	25-12 mW

Table 1. Oscillator performance vs. load vswr and frequency. This table indicates the oscillator power output for five different diodes at frequencies from 10.0 to 10.5 GHz. The load vswr was varied through all phases of a 2 to 1 mismatch. Diodes 1 through 3 are Alpha type DGB 6844C operated at 8 volts. Diodes 4 and 5 are Microwave Associates type MA 49508 operated at 7 volts.

supply oscillates. A series RC circuit consisting of a .1 μF capacitor in series with a 33-Ohm resistor keeps the supply impedance down in the low megacycle region and prevents low-frequency breakup of the oscillator output. With the diodes specified, the heat-sink end of the package is the anode and the diode is installed with this end inserted in the capacitive mounting post. The flanged end of the diode is the cathode and is grounded to the waveguide with the 10-32 mounting screw.

A word about current limiters. The threshold current of the Gunn device is much higher than the operating current. The current limiter on the supply should be set well above the threshold current. For the diodes used here, 500 mA is a good setting.

If the current limiter is set at the operating current, the supply will limit on the low-voltage side of the threshold voltage and the operating voltage will not be achieved. From Fig. 2 it may be seen that there are two points at which the diode will draw the same current, one above and one below the threshold voltage. Don't worry about protecting the diode from excessive current. In this case, lowering the voltage *increases* current, so a normal current limiter does not help. Just set up the supply for the proper voltage and make sure the current limit is set to 500 mA. Then connect the Gunn-diode circuit. If the current limiter is set as above, it is okay to just switch the supply off and on with the power switch. Do not turn up the voltage slowly because the diode will be subjected to more current than if power is suddenly applied. Using these methods, I have yet to lose a Gunn device. Supply oscillations may be checked by connecting a scope across the supply. If the dc line has only dc on it, you can assume that all is well. If oscillations are present, they are generally of high amplitude (several volts) and are easily detected. If this does occur, one fix is to adjust the R and C of Fig. 8. Reduction of the hole in the coupling iris plate may also help. No difficulty was encountered with supply oscillations for a variety of Gunn diodes tried in the cavity provided the circuit of Fig. 8 was used. Dc supplies included commercial and home-built bench supplies and the three-terminal regulators used in the Doppler processor described below.

To set up the oscillator for test, there are only three adjustments: the tuning screw to set the frequency, the output iris diameter which determines load stability and power output, and the depth of the parasitic suppression probe. The tuning screw should be set at minimum penetration of the cavity. The resistive probe should penetrate about .150 inches into the cavity. With the .290-inch iris installed, the oscillator should make at least 10 milliwatts of output. If it does not appear to be oscillating or if it is oscillating weakly (a −20 dBm output), insertion of the resistive probe to a greater depth is indicated because the diode-mount resonance at 13 GHz may be in the act. The three models of the oscillator worked fine with the probe at .150-inch penetration, so you should not have to adjust it. It is not very critical. Once oscillations are obtained, the tuning screw is used to set the operating frequency. The unit will easily tune the 10.0- to 10.5-GHz band with either diode installed.

The selection of output iris diameter depends upon application. To determine which diameter is best for

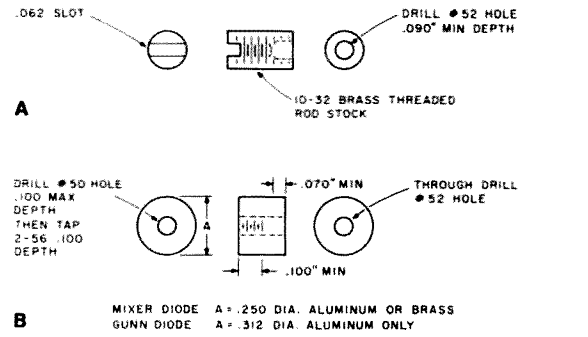

Fig. 7. Diode-mount details. (a) Diode-mounting screw. (b) Diode heat-sink post. The diode heat-sink post is first drilled through with a number 52 drill. The hole is then enlarged to a number 50 size and tapped for the 2-56 turret terminal. The number 52 diameter must be maintained for a depth of at least 0.070 inches to assure proper heat transfer from the diode.

your use, review the tests and test data I obtained.

A shift in load impedance will change both the frequency and power output of any oscillator, crystal, LC, or a microwave type. I made several tests to evaluate the effect of load shifts on this circuit. In addition, the ability to tune the frequency of the circuit with the supply was tested. I found that if the load vswr is less than 2 to 1 and its phase is stable, the frequency will pretty well stay put. If the vswr is controlled and it is less than 2 to 1, the supply may be used to make corrections in the oscillator frequency of up to 20 MHz.

Fig. 9 is a sort of schematic of the waveguide setup I used to test the oscillator. The setup allows the power output and frequency to be measured and a vswr of any desired magnitude and phase to load the oscillator. The oscillator is connected to the main line of a cascade of three directional couplers. The first coupler samples the output power and frequency. The power is detected and displayed on meter M3. A cavity wavemeter in the line absorbs power at its resonance and causes a "suck-out" or dip on M3 when tuned to the oscillator frequency. The next two couplers form a reflectometer which reads the forward and reflected power from the load as seen by the oscillator. M1 reads forward power and M2 reads reverse power.

At the output of the last coupler, a device called a slide-screw tuner is connected. This is followed by a matched waveguide load.

The slide-screw tuner is a simple way to get an adjustable vswr of any phase. It is useful in load tests such as this or as an impedance-matching device. The VHF equivalent is a single-stub tuner which may be moved along the line. Mechanically, the slide-screw tuner consists of a probe through the broad wall of the waveguide (often a screw) which travels in a slot in the waveguide wall. The probe is supported by a slide plate on the outside of the guide. The probe when inserted into the guide is equivalent to a capacitor, the value of which is proportional to the depth of penetration. The depth of penetration controls the magnitude of the imaginary part of the vswr thus created. The position of the probe along the guide controls the phase. The real part of the load is sup-

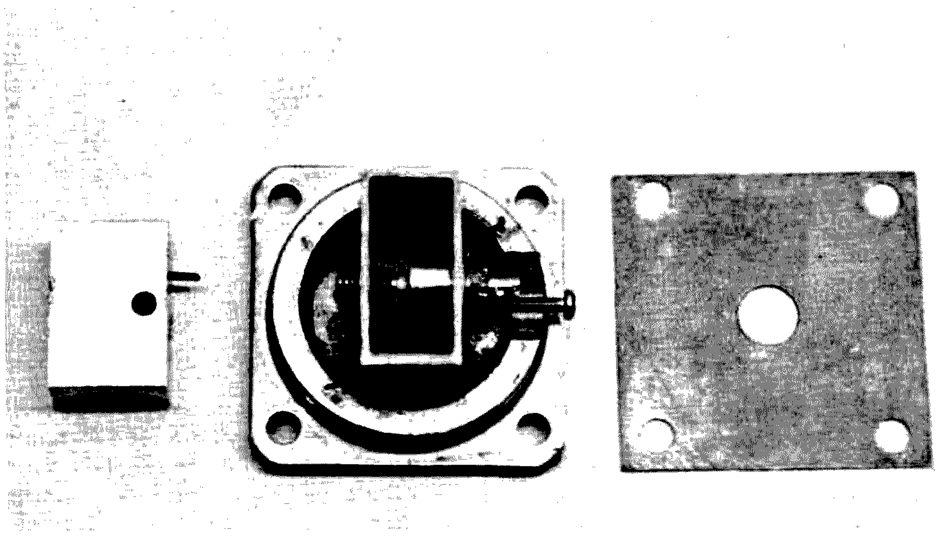

Photo C. The partially-assembled oscillator. The breadboard version of the oscillator is shown with the shorting block and iris removed. The lossy resistive probe extends from the shorting block into the cavity. The removable iris plate permits the output coupling to be easily adjusted.

plied by the waveguide load beyond the tuner. By moving the probe along the guide, a fixed vswr load is effectively rotated through all phases.

I tested my oscillator with load vswrs of 2 to 1. Most waveguide circuits into which such an oscillator will operate may be tuned below a 2 to 1 vswr without much difficulty. In addition, the phase of most loads will stay put. A 2 to 1 vswr of variable phase is probably the worst load that might be expected in most applications.

The first test I made was load pulling. This measures how much the power output and frequency shift as the load vswr is rotated through all phases. The setup of Fig. 9 is used. The oscillator was connected and the center frequency set by means of the tuning screw.

The slide-screw tuner was initially completely out of the waveguide, so the oscillator load was only the matched waveguide termination. To obtain a 2 to 1 vswr, the slide screw was inserted into the guide until the reflected power indicated by M2 increased to a level 9.5 dB below the forward power indicated by M1. A ratio of forward to reflected power of 9.5 dB corresponds to a 2 to 1 vswr.

The shift in load impedance caused the reading on M1 to change also as the probe was inserted into the line. The idea is to get the 9.5 dB difference with the probe inserted. The initial value of M1 is not of concern, as it will always change as the probe is inserted. I then had a 2 to 1 vswr load on my oscillator. The next step was to move the probe of the slide-screw tuner along the line and record the extremes of power and/or frequency. During these tests, a spectrum analyzer was often used in place of the wavemeter to speed the measurement process, but the wavemeter approach works fine. It just takes longer.

First, I measured the effect of load vswr on the oscillator power output for 5 different Gunn diodes. Three Alpha type DGB 6844C diodes were tested at their normal operating voltage of 8 volts. Then two Microwave Associates type 49508 diodes were tested at 7 volts. Table 1 shows the data for 10 to 10.5 GHz in 100 MHz steps. In my oscillator, the Alpha diodes gave slightly more power output. An average output was obtained of about 25 milliwatts for most Alpha diodes at most frequencies. The average for the MA devices was a bit less, about 15 milliwatts. Diodes could be substituted in the oscillator with no adjustment and the frequency would change only a few MHz. This data was taken with a .320-inch iris installed on the oscillator.

In order to determine the effect of various iris sizes, I next made a set of tests with different iris diameters and used the same diode. Iris sizes of .290, .320, and .380 inches in diameter were tried. The pulling was again tested with a 2 to 1 vswr. I found that the effect was considerable. Table 2 shows the results. Increasing the iris hole size increased the output power by about 2 dB. The effect on the frequency stability and cavity Q (determined from the amount the oscillator can be pulled) was significant. The pulling increased from 21 MHz with the small iris to 80 MHz with the large iris. In addition, the oscillator would not operate below about 10.4 GHz. At the heavy loading caused by the large iris, insufficient negative R was available and the oscillations stopped. This is because the optimum operating frequency for this diode was above 10.5 GHz for the particular dc voltage applied.

The .320-inch diameter turned out to be a good size. High power output and pretty fair stability were obtained. The data indicates how a little rf power can be traded for a lot of frequency stability. For low-power applications such as receiver local oscillators, I would use a small iris. The improvement in frequency stability for varying loads is certainly worth it.

The dc supply voltage may be used to adjust the oscillator frequency slightly. This is a simple way to make an afc system if done carefully. The tuning range is not as great as can be obtained by putting a varactor diode in the cavity, but it is an easy approach. The tuning range is limited by the amount the supply can be changed before the oscillator quits. For small diodes such as those used here, a variation of plus or minus 1 volt from the nominal supply of 7 or 8 volts seemed reasonable. Lower voltage increases the current and power drops. Increased voltage will also drop the power and the oscillator will eventually quit as the electrons are slowed from the optimum transit-time velocity.

I tested the oscillator into a matched load and measured the degree of frequency "pushing" that could be obtained. The smallest iris was used since an afc system would require that the best oscillator load-stability option be used.

The three Alpha diodes were used for this test. I set the cavity to 10.5 GHz with the dc supply at 8 volts. The voltage was then changed plus and minus 1 volt in one-half steps and the frequency shift noted. The data is in Table 3. All diodes behaved the same. The frequency could be shifted down about 15 MHz and upward about 8 MHz. The power variation was only 4 milliwatts out of about 15 milliwatts average. This is quite acceptable for most applications.

After making this test, I began to wonder what effect the load vswr would have on the frequency "pushing" sensitivity of the oscillator. An especially unfortunate change in load could pull the oscillator so far that it could not be returned to the correct frequency by "pushing" with the dc supply. In order to cut down the time to take the data, only a single diode sample was tested. The great similarity of results for the other tests indicates that these results are probably valid for the other diodes. Alpha diode number 1 was used with the .290-inch iris on the cavity output. First, I varied the supply voltage as before and noted the frequency shift obtained with a matched load. Table 4 shows the data. Next, the vswr was increased to 2 to 1 and the frequency was pulled up the band as far as possible (the dc supply was returned to 8 volts during this adjustment). Next, I varied the supply again and noted the frequency relative to the *original* 8-volt center frequency. Finally, the oscillator was pulled down the band as far as possible with the load vswr and the data was taken again.

From the data, it may be seen that the range of adjustment with a matched load is −15 to +8 MHz. With the frequency pulled high with load vswr, the range is −25 to +17 MHz. The oscillator passed through the reference frequency somewhere between 7.0 and 7.5 volts. In this case, the supply could be used to afc the oscillator back to the starting frequency. With the oscillator pulled below the operating frequency, the range of adjustment with the supply was from −25 to −6 MHz. Nowhere in the range of supply-voltage adjustment did the oscillator return to the initial frequency. In this case, an afc loop could not correct the frequency shift due to load pulling. It could only approach within 6 MHz and would "hang up" on the low side as indicated in the fourth column of Table 4.

One other factor is evident from these results. The modulation sensitivity varies a lot as a function of load. For the matched load case, the shift for a 0.5-volt change from 8.5 to 9.0 volts is only 3 MHz. With the oscillator pulled high, the change in frequency as the supply is varied from 7 to 7.5 volts is 30 MHz. With the oscillator pulled low (column 4), the frequency change for the same supply-voltage shift is only 7 MHz.

My conclusion is that an afc or phase-lock system that uses the supply voltage is feasible, but with a few cautions. The load vswr that the oscillator sees should be low if at all possible, and it certainly should be controlled.

If this is not done, the loop may lose range or go unstable. When setting up an afc system, the oscillator should be mechanically tuned to the desired frequency while monitoring the supply voltage so that it may be centered with the loop closed. Because the amount of tuning that can be obtained is so limited, this approach will ensure that all of the range is available to cope with thermal drift. If the load changes significantly, the loop may well lose control.

The real key is to keep the load vswr as low as possible. This will minimize the effect of changes in load phase upon the oscillator frequency.

This concludes the test data I obtained. Hopefully, it is complete enough so that the oscillator may be put to use in your X-band command link or whatever.

X-Band Transceiver

I added a simple mixer to the basic oscillator to make an effective X-band transceiver. My application was for Doppler radar, but the device is equally useful for communications. When mated with the Doppler processor described in the next section, the unit will provide positive detection of man-sized targets at ranges up to 100 feet or so.

A number of the commercial Doppler radars used for door openers, speed meters, or intrusion detection use a simple "diode in the guide" mixer for reasons of cost. In this approach, a mixer diode is simply placed in a section of waveguide between the Gunn oscillator and the antenna-mounting flange. No ferrite circulator is used for transmit-receive signal separation. At best, this approach is 6 dB poorer in performance than if a circulator is used, but it is simple to make and works quite well for many applications.

In operation, a portion of the transmitted energy is intercepted by the mixer diode. For communications, this serves as the local oscillator, and in a Doppler system it serves as the zero-velocity frequency reference. The amount of energy that is coupled to the diode must be controlled so that there is something left to radiate. In my design, this was done by offsetting the diode from the centerline of the waveguide. The electric field intensity is maximum at the centerline of the guide and falls off toward

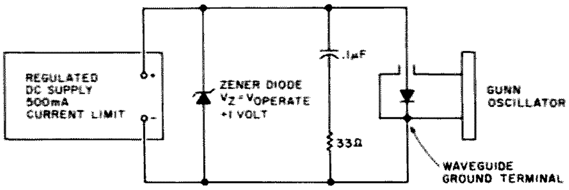

Fig. 8. Dc power-supply circuit for testing Gunn-diode oscillators. The zener-diode voltage should be about 1 volt more than the intended operating voltage for the oscillator.

Iris Diameter Inches	Power Output Milliwatts	Frequency Pulling MHz peak to peak	Loaded Q
.290	15 to 32	21	250
.320	22 to 40	40	131
.380	35 to 45	80	65

Table 2. Effect of iris diameter. This table shows the effect of iris diameter upon the power output and frequency stability of the oscillator as the load is varied through all phases of a 2 to 1 vswr. The test frequency was 10.5 GHz. Diode number 3 was used for this test. The oscillator would not operate below 10.4 GHz with the .380-inch iris.

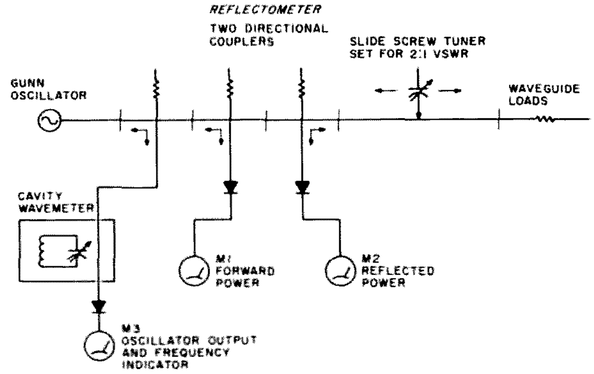

Fig. 9. Schematic of the Gunn-oscillator test setup.

the sides. It is zero at the side walls since they effectively short the field.

I positioned the diode mount 0.250 inches from the outer wall of the waveguide. At this location, about one-half of the energy from the Gunn oscillator is intercepted by the diode. The rest continues down the guide to the antenna.

The iris on the Gunn-oscillator output port is not a perfect short, but it does present a very high vswr to the guide. This is fine for the oscillator coupling because the goal is to mismatch the oscillator so that it is decoupled and the cavity Q remains high. It also effectively shorts the guide behind the mixer diode for energy entering the transceiver from the antenna. The presence of the iris means that the electric field will be maximum about one-quarter wave up the guide from the iris plate because it has to be nearly zero at the iris.

I placed the mixer diode three-quarters of a wavelength from the plate. Since impedances repeat every one-half wave, the three-quarter-wave position is equivalent to the quarter-wave location. This was done to put the diode far enough from the iris for the energy from the oscillator to return to the normal TE_{10} mode pattern. I was concerned that the desired coupling to the diode might be difficult to obtain near the iris and didn't want to spend a lot of time in optimization of the circuit.

The mixer diodes used in my transceiver were chosen because they are in a package similar to the ones housing the Gunn diodes. The same sort of mount is used and all of the pieces are the same with the exception of the post, which is smaller. I purposely avoided the 1N23 type of package because it is hard to mount and a second set of hardware would have to be designed for it.

Dc supply voltage	Diode #1 Freq. Shift	Diode #1 Pout mW	Diode #2 Freq. Shift	Diode #2 Pout mW	Diode #3 Freq. Shift	Diode #3 Pout mW
7.0	−15	14.2	−18	20	−15	19
7.5	−7	14	−10	17	−8	21
8.0	0	14	0	16	0	20
8.5	+5	15	+6	17	+6	19
9.0	+8	15.5	+10	18	+10	17

Table 3. Frequency pushing with supply voltage. This data shows the effect of supply voltage upon the oscillator frequency with a matched load. The iris diameter was .290 inches. The oscillator was tuned to 10.5 GHz with the supply at 8 volts to establish the initial reference frequency.

Diodes in the small (double prong or MQM) package are made by Microwave Associates, Alpha Microwave, and Hewlett-Packard, to name a few vendors. I used the H-P 5082-2711 diode in my transceiver. This is a Schottky barrier type. Other diodes which should work include the Alpha type DMF 6106 and the MA type 40006. These are also Schottky types. A point-contact type which may prove cheaper to buy is the Alpha type D5523C. The point-contact diodes will work as well as the Schottky diodes in most applications. Remember when ordering these diodes to get ahold of a data sheet because they are graded for noise figure. The numbers above I selected for worst noise figure and lowest cost. By changing a suffix or adding one, the noise figure gets better and the price gets worse. No diode listed above has a noise figure of more than 9 dB. You can get 6.5 dB, but boy, it will cost!

Transceiver Construction

Photo F shows the breadboard version of the transceiver. Photo D shows the final version which eliminates the two flanges coupling the oscillator to the mixer. It is mounted upon the Doppler processor box. The integrated version of the transceiver is made from a single section of X-band waveguide. The oscillator section is identical to the separate oscillator circuit just described. All of the internal details are the same with the exception of the coupling iris; it is soldered directly into the guide.

Two flanges are eliminated and a nicer assembly is achieved. To install the iris, first cut through three of the four walls of the waveguide, as indicated in Fig. 10. One broad wall and the two narrow walls are cut. Make up the iris plate from copper or brass sheet somewhat thinner than the saw blade. Install the iris in the saw cut and solder into place. Take some care in this. All four walls of the guide must be soldered to the iris plate on both sides. If not, you will create a truly marvelous slot antenna! Remove all flux after soldering.

The mixer diode is installed in a mount similar to the Gunn-diode mount. The mount parts are as indicated in Fig. 7. The mixer post is made from 0.250-inch rod stock rather than the .312-inch-diameter stock used for the Gunn diode. The mixer-mount parts are assembled into the guide in exactly the same manner as the Gunn-diode mount. There is one difference. No heat-sink goo is required for the mixer diode. Hole A on the mixer side of the iris is for a ground lug to return the mixer load resistor to the guide. This resistor is used to prevent static burnout of the mixer diode during initial testing.

In assembling the transceiver, first cut the guide to length and then drill and deburr all holes. Tap holes as required. Make the saw cut and install the iris. Solder the output flange to the mixer section as indicated in Fig. 10. Use a large C-clamp to heat sink the iris area when installing the output flange. This will prevent the solder holding the iris plate from running. Remove all flux. The two diode mounts may be installed next. Then install the shorting block with lossy probe in the end of the oscillator cavity. Install the tuning screw. Install the Gunn diode. Connect a 5k resistor from the mixer-diode output terminal to the ground lug. Now install the mixer diode using care not to damage it with static. Pick up the transceiver body with one

hand while holding the diode in the other. This will put the transceiver and the diode at the same potential. Then install the diode in the transceiver. The Gunn diode is more rugged and may be handled normally, so these cautions do not apply to it. In my version of the Doppler radar, I located the .1 μF capacitor and 33-Ohm resistor components of the Gunn-diode dc supply circuit on a small tie strip. This tie strip is mounted to the waveguide by the same screw that holds the shorting block in place. These parts are visible in the photo.

The transceiver is now ready to be tested.

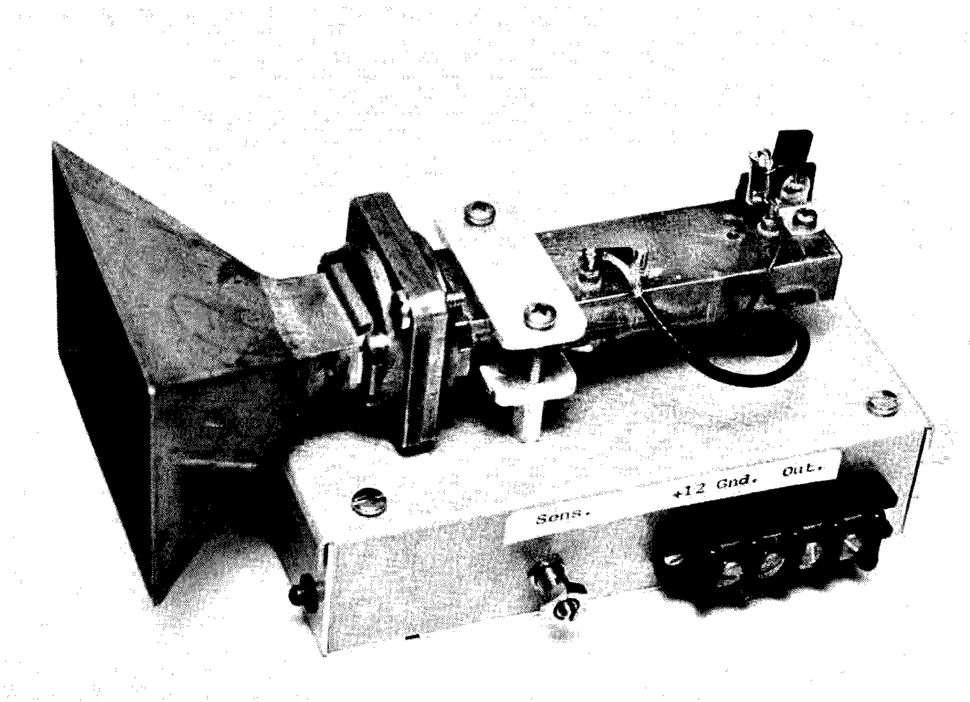

Photo D. The Doppler radar assembly. The final version of the X-band transceiver is mounted to a box which contains the Doppler processor to form a self-contained Doppler radar. The 10k-diode load resistor may be seen to the rear of the coax cable which connects the mixer output to the processor card. The 33-Ohm resistor and 0.1 μF capacitor are mounted on the small terminal strip and connected to the Gunn-oscillator dc input terminal. The 2-56 cavity frequency adjustment screw is not installed in this photo. One of the two LEDs used for adjustment is visible under the horn antenna.

Transceiver Test

Arrange a power supply for the Gunn diode as described previously. Apply power and test for supply stability with a scope. If everything is okay, the oscillator should be operating. Connect a voltmeter (20,000 Ohms/volt) to the mixer-diode output. Do this with care. Ground both meter leads to the waveguide and then connect the positive lead to the diode output. The diode should be rectifying some of the rf energy and a voltage of a few tenths of a volt will be present. If the diode voltage is negative with respect to ground, the diode is in backwards. This is of no concern in most applications.

If no voltage is measured, there are three possibilities: The diode is no good, the Gunn is going at 13 GHz and no power is coming out of the oscillator, or perhaps the tuning screw is in too far and is shorting the cavity. First, back out the tuning screw until it is out of the guide. Next, try another mixer diode. If this doesn't help, remove the shorting block from the cavity and verify the pencil-lead probe insertion. If it is okay, then make sure that it is soft pencil lead, which has more carbon in it. Reassemble the oscillator without the probe. Set up as before and apply power. Observe the voltmeter on the mixer diode and slowly insert the lossy pencil-lead probe into the cavity through the hole in the shorting block. If a diode-mount oscillation was the problem, the mixer diode will suddenly indicate the presence of rf when the probe kills the spurious oscillation.

Once things are going, some interesting tests can be made. The open waveguide flange is not a bad antenna. The gain is about 5 dB! Point the business end of the transceiver out into the room and connect a scope across the mixer-diode output. With the scope gain at 10 to 100 millivolts per division and ac coupling, the Doppler shift on moving people is quite readily seen. Adding a good antenna will greatly increase the return. Hooking the mixer output into a hi-fi amplifier with a good low-frequency speaker is also entertaining. People, fans, and cars make really strange Doppler noises.

If you build two transceivers or an oscillator and transceiver, the following test is interesting. Set them up about 6 feet apart with the waveguides pointed at each other. Observe the mixer output of one unit on a scope while tuning it across the frequency of the other. The diode-mount capacitance measures about 13 pF, so a bandwidth from dc to several megacycles is obtained without tuning the mount at i-f. As the frequency of one unit approaches that of the other, the beat may be seen on the scope. This is the i-f frequency created by mixing the two X-band signals. As the frequencies are brought closer, the beat frequency drops and then it will suddenly vanish. This happened at about one MHz with my units. At first this seems strange, since the mixer mount will work down to a dc i-f frequency.

The answer is that the two oscillators have locked together and are now on the same frequency. Further tuning will eventually pull them apart. This is an example of injection phase locking. In some high-power sources, injection locking is used to obtain more power than a single diode will supply by locking several units together. As you can see, not much power needs to be injected to lock one to another.

Communications

The transceiver may be used for communications.

mixer: −86 dBm
Sensitivity: −100 dBm

Output carrier-to-noise ratio: +14 dB

The actual signal-to-noise ratio will be somewhat better because of the FM improvement resulting from the high modulation index if the full 75 kHz deviation is used. By going to a pair of 3-foot dish antennas, a gain of about 36 dB is obtained. This will improve each end of the link by 16 dB for a total gain in SNR of 32 dB over the case above. Of course, the improved SNR can be traded for greater range at the rate of an additional 6 dB of loss for each doubling of the distance.

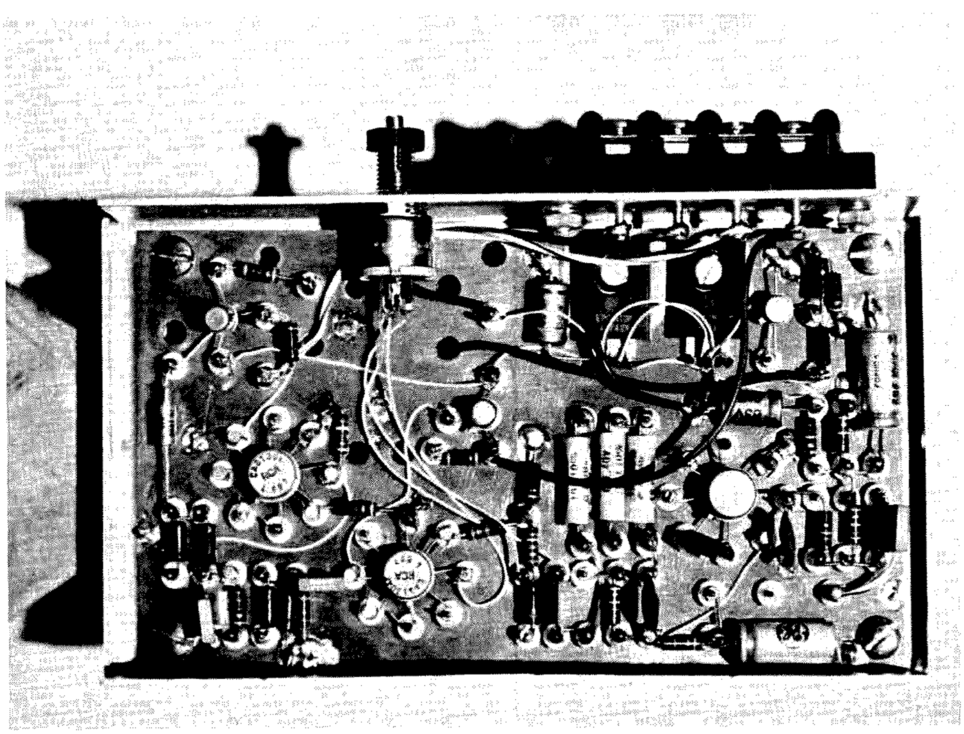

Photo E. The Doppler processor card. Signal flow is from right to left across the bottom of the card. U1 is located at the lower right, U2 in the center, and U3 at the left of the card. The analog pulse-counter circuitry is in the lower left-hand side of the card below U3. The voltage-regulator circuits are at the upper right near the input/output terminal block.

An FM tuner makes a good i-f strip for getting started. Most of the tuners have a pretty fair noise figure, but getting a proper match to the mixer is also important if good results are to be achieved. Most modern microwave receivers solve this problem by putting a preamplifier right at the mixer. I recommend doing the same. A good low-noise dual-gate FET preamplifier will overcome any deficiencies of the FM radio and will enable the mixer to be matched to a well-controlled amplifier input impedance. The preamplifier can then drive a cable to the receiver.

The i-f impedance of the mixer will be a function of the diode current and will be from 200 to 500 Ohms. The diode mount has a capacitance of about 13 pF. This should be tuned out with an inductor which also serves as the dc return for the diode, as in Fig. 11. The inductor and diode-holder capacitance should be resonant at the i-f frequency. The resulting real impedance is then matched into the preamplifier.

FM modulation of the Gunn diode is simply a matter of modulation of the power-supply voltage. Be sure to limit the peak-to-peak excursion of the supply to prevent damage to the diode. A good modulator approach would be to ac couple the audio into the reference source for the dc regulator. This will offset the reference and force the dc voltage from the supply to follow the audio. The supply must be capable of moving at audio rates. This means that giant filter capacitors on the output cannot be used. In addition, some form of modulation limiting should be provided so that deviation is controlled. Remember, the oscillator can be deviated several MHz per volt of supply change. If a standard FM radio is used as your i-f strip, only 75 kHz of peak deviation is needed. So only a few hundred millivolts of audio are required on the dc supply.

The communications range that you can get with this transceiver is very much dependent upon the antennas used. The noise figure is fairly decent, and, with a 200 kHz bandwidth FM tuner for an i-f strip, sensitivities of −100 dBm or so should be obtained. The path loss at 10 GHz for 10 miles is 136 dB.

As an example, consider the use of a pair of 20 dB gain horns and about 10 milliwatts of power. The power at the receiver mixer and output carrier-to-noise ratio are:

Transmitter output: +10 dBm
Transmitter antenna gain: +20 dB
Receiver antenna gain: +20 dB
Path loss (10 GHz & 10 miles): −136 dB

Power at the receiver

Doppler Processor

The X-band transceiver may be used as an effective Doppler radar for protecting the goodies in your ham shack from burglars by adding the Doppler processor section described next. Doppler radars respond only to moving reflectors, and, if properly employed, can provide nearly foolproof protection against intruders. The trick is to achieve a very low false-alarm rate so the circuit is not continually "crying wolf."

The Doppler effect refers to an apparent shift in the frequency of a radio signal which occurs if the transmitter is moving relative to the receiver. The amount of frequency offset that occurs is determined by both the transmitter frequency and the velocity of the transmitter relative to the receiver. The frequency shift is given by the simple formula: $F = f_0 \times V/C$. F is the shift. f_0 is the transmitter frequency. V is the velocity difference and C is the speed of light. The frequencies are in Hz and the velocities in meters per second. In the radar case, the signal experiences the Doppler effect in

both directions of propagation, to and from the target. Here, the resulting shift is doubled from the values given by the formula.

The Doppler effect is used in a variety of radar applications where measurement of speed or separation of moving from stationary targets is desired. The police speed meters are one example, of course, but others include air search radars which use Doppler to reject ground clutter (ground doesn't move) and accept airplanes (which always move).

If an intrusion-detection radar operates at 10 GHz, the maximum Doppler shift obtained with a walking person as a target is about 40 Hz. The lower end of the Doppler range extends to very low frequencies. I used 4 Hz as the lower band edge of the processor after observing the Doppler output of the transceiver on a scope and determining that there is a lot of energy near dc; some of us don't move all that fast! In any event, the 4-40 Hz processing bandwidth seems to work well in practice.

The objective in the processor design is to obtain positive target detection with a low false-alarm rate. The circuit has to have some "smarts" so that it does not trip on the first cycle or two of 4-40 Hz audio to come out of the Doppler mixer. In order to obtain an alarm output, the processor requires that a large number of cycles of Doppler occur within a relatively short span of time and that more recent events be given greater weight than those which occurred many seconds earlier. This feature prevents noise from causing single-event false alarms, and, as a consequence, the circuit almost never produces a false output. An alarm output on a real person is obtained in about 2 seconds.

The processor has four major sections: an input preamplifier, a squaring amplifier, a pulse counter, and an output threshold detector. It also contains a power supply for the processing circuits and a regulator for the Gunn-diode oscillator. Two LED indicators are provided to aid in setting the circuit sensitivity. One blinks when Doppler is present; the other indicates an alarm-decision output. Fig. 12 is a schematic diagram of the circuit.

The input preamplifier has a 4-40 Hz bandpass which is obtained by RC rolloffs in the input and feedback networks. The op amp, U1, is an RCA type CA 3130 FET input op amp. I used this part in all three stages of the processor because it has a number of advantages for this type of circuit. The high-input impedance permits good low-frequency response with small (0.1 μF) capacitors. If a 741-type amplifier were used, some truly huge values would be required to obtain response to 4 Hz. The FET input stages also permit the CA 3130 to run from a single-ended supply with the common-mode input voltage at the inputs as much as one-half volt below ground. This was handy in the last stage. Finally, the output section of this chip is a CMOS inverter used as an amplifier. This permits the output to swing within 50 millivolts or so of the supply voltages. Thus the circuit will interface directly with CMOS and, in the case of the squaring amplifier stage, will provide an output swing equal to the supply voltage. This saved some parts.

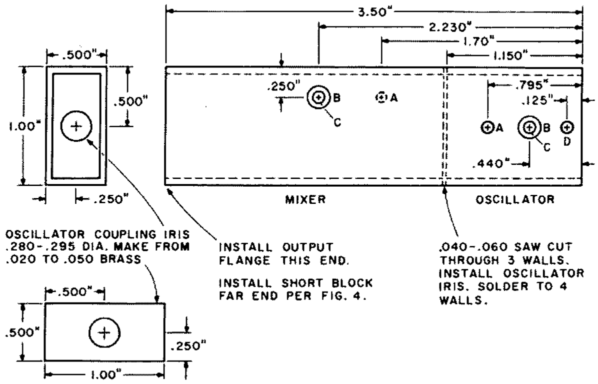

Fig. 10. X-band transceiver waveguide. The function and size of the lettered holes are the same as in the table in Fig. 6.

The noninverting input of U1 is biased at +5 volts by the voltage divider, R3 and R4. Input capacitor C1 and resistor R1 form a high-pass filter with a 4-Hz corner frequency. R2 and C2 form a 40-Hz low pass. The amplifier gain is set to 60 dB by feedback resistors R5 and R6. Capacitor C5 is used to obtain a 40-Hz high-pass rolloff in the feedback network. The 68 microfarad capacitor, C4, in conjunction with R6, causes the gain to decrease below 4 Hz. The amplifier gain is unity at dc so the output sits at the input bias point of +5 volts in the absence of an input signal. High-frequency compensation of the preamplifier requires a 100 pF capacitor from pin 1 to pin 8 as indicated.

The second stage of the processor, U2, also uses the CA 3130. Positive feedback around the amplifier is employed to obtain a squaring amplifier. The objective is to turn the complex sine-wave Doppler audio into a series of 10-volt peak-to-peak square waves. The input circuit of U2 is a bit novel and requires some explanation. The voltage divider consisting of R7, R8, and R9 forms the reference for both the inverting and noninverting inputs. This reference voltage is about 5 volts. The 6.8-Ohm resistor, R8, ensures that the voltage at the inverting input is always about 34 millivolts more positive than the noninverting input. In the absence of an audio input signal (which is ac coupled), the op amp is always driven to ground potential because of the intentional 34 millivolt offset introduced between the inverting and noninverting

Dc supply voltage Volts	Frequency shift matched load vswr 1.1 to 1	Frequency shift osc. pulled high with 2 to 1 vswr	Frequency shift osc. pulled low with 2 to 1 vswr
7.0	−15 MHz	−25 MHz	−25 MHz
7.5	−7 MHz	+5 MHz	−18 MHz
8.0	0 MHz	+10 MHz	−14 MHz
8.5	+5 MHz	+13 MHz	−7 MHz
9.0	+8 MHz	+17 MHz	−6 MHz

Table 4. Effect of load vswr on frequency pushing. This table indicates the effect of load vswr upon the center frequency and tuning sensitivity of the oscillator. Note that when the frequency was pulled low, the initial frequency could not be restored with supply voltage. Diode number 1 was used with a .290-inch diameter iris.

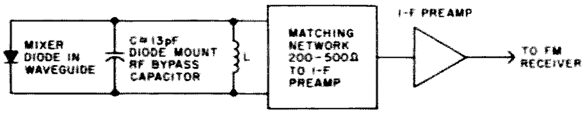

Fig. 11. Connection of an i-f preamplifier to the X-band transceiver. C is the shunt capacitance of the diode mount (about 13 pF). Inductor L tunes the mount capacitance to the i-f frequency and provides a dc return for the crystal current. A 3N200 or similar dual-gate FET would make a suitable preamplifier.

inputs. This offset is sufficient to overcome the worst case input offset of the op amp and ensures that the output voltage always swings to ground. This is done so that the LED driver, Q1, is normally off.

The particular configuration used was chosen because it is independent of both supply-voltage and resistor variations. No precision parts are required.

The Doppler signal is coupled into the squaring amplifier input from the preamplifier stage via capacitor C6 and gain control R10. When R10 is set to full gain, less than 50 millivolts of Doppler at the input to the squaring amplifier is sufficient to obtain a 10-volt peak-to-peak square wave output from U2. The presence of Doppler causes LED −1 to flash at the Doppler rate.

The circuitry following U2 is the heart of the processor. It is here that the low false-alarm rate is obtained. In effect, the circuit is an analog pulse counter with a short memory. The first section, consisting of C7, R13, and CR1, is a rectifying differentiator. It converts the square waves from U2 into a series of short positive-going pulses. The shunt diode rectifier clips all negative-going edges so only the positive pulses remain.

These positive pulses charge C8 through R14. The series 1N914, CR2, prevents the accumulated charge from discharging back through R13 to ground. The effect of R14 is to make the narrow positive pulses into a current source. As a result, the voltage accumulated in C8 is a function of the number of input pulses. The circuit is essentially a pulse counter with an analog voltage output.

This approach is simpler and cheaper than a digital counter and can be made to "forget" at any rate desired. The objective is to have the circuit slowly reset itself if an insufficient number of pulses are counted. This is a way to give more recent events more weight in determining if there is an intruder present. Two groups of pulses separated by a short interval in time should set off the alarm. Similar groups spaced widely apart in time (several minutes apart) should not. The "forget-it" function is obtained by R17, which slowly discharges C8. Adjustment of R17 allows the circuit to have any memory time required.

The output of the analog pulse counter is applied to U3, another CA 3130 op amp. U3 functions as both a high-impedance comparator and as a one-shot multivibrator. The inverting input of the amplifier is referenced to +2 volts by R15 and R16. The voltage from the analog pulse counter is applied to the noninverting input. When this voltage is less than +2 volts, the output of U3 is 0 volts. When the input exceeds +2 volts, the output of the CA 3130 goes to +10 volts and the circuit becomes a one-shot.

The one-shot functions as follows: C9 is initially discharged via CR4. CR3 is reverse biased, which effectively disconnects C9 from the input to U3. Thus, the only capacitor in the pulse counter circuit is C8. When the output of the CA 3130 goes to +10 volts, CR3 becomes forward biased, and since C9 is essentially discharged, the voltage at the noninverting input of U3 is nearly 10 volts. This positive feedback holds the output of U3 at +10 volts. C9 starts to charge through R17 and the voltage at the noninverting input falls toward ground at a rate determined by the R17 and C9 time constant. C8 is also in the act, but to a lesser extent because of its lower capacitance relative to C9. Eventually, the voltage at pin 3 drops below +2 volts and the circuit resets. The output voltage from U3 then returns to ground potential. The output pulse width is more than one second with the values shown. The arrangement of the circuit is convenient in that longer pulse widths may be obtained by increasing the value of C9 without any effect upon the analog pulse counter. In one version of the circuit, the output pulse width was increased to 3 minutes by increasing C9 to about 60 μF. In this application, the output pulse operated an alarm circuit directly for a 3-minute interval.

The LED drivers, Q1 and Q2, are 2N2222 or similar NPN transistors connected as emitter followers. Just about any LED will work. I used the high-efficiency HP 5082-4650 types which make a lot of light from only 10 mA of current. If lower-efficiency LEDs are used, the 820-Ohm resistors, R18 and R19, may be reduced in value to obtain more current. Note that the LED driver collectors are returned to the unregulated +12-volt line and not to the +10-volt regulated supply. This is intentional. The current pulses created by the LED drivers could get back into the low-level input stages and cause an oscillation via the +10 supply line. By using the connection indicated, the voltage regulator isolates the low-level stages from these current pulses.

The Doppler processor operates from a nominal 12- to 15-volt dc input. Higher voltages can be used if the heat sinking of the supply regulators is improved. A 10-volt supply was chosen for the op amps to ensure sufficient "overhead" to maintain the voltage regulator in regulation. The CA 3130s require at least 8.5 volts to really work well. The regulator for the Gunn-diode oscillator supplies +7 volts and is compatible with the Microwave Associates Gunn diodes. The 8-volt Alpha parts will also work from this voltage.

The regulator circuit was designed to supply the 7- and 10-volt requirements using standard 5- and 8-volt 3-terminal regulators of the MC7800 series. Seven volts is obtained by offsetting the common terminal of U4, a MC7805 CP, 2 volts above ground. This is accomplished with emitter follower Q3, which has its base referenced to a divided sample of the 7-volt regulator output. The sample is derived from divider R22-R24. Resistor R24 is a select in test value and is used to adjust the circuit to exactly 7 volts of output. The divider cannot be fixed because of the wide output-voltage tolerance of U4 and the variations of V_{be} of Q3. The +10-volt regulator is made by referencing the common terminal of an 8-volt three-terminal regulator chip to the +2-volt source at the emitter of Q3. The current from the common terminal

to ground for both chips runs through Q3. An emitter follower was used rather than a simple resistive divider to provide a low-impedance constant voltage sink for this current and to avoid the necessity for high-dissipation low-value resistors in the voltage-divider network.

Doppler Radar Construction

The complete Doppler radar is packaged in a 5.5" x 1.5" x 3.0" minibox as indicated in the photos. The X-band transceiver is mounted to the top exterior surface of the box with a clamp which grips the waveguide. The Doppler processor card is mounted inside the box and attached to the same surface as the waveguide. The card is mounted with number 6 screws and spacers. This arrangement makes it possible to remove the bottom cover for test or servicing without disturbing any wiring. The sensitivity control and input/output terminal strip are mounted on one side of the box. The LED indicators were mounted on one end of the bottom cover and connected to the circuit card with long leads to permit easy removal of the cover.

The Doppler processor card is constructed using copperclad PC board and push-in standoff terminals. Wiring is all point-to-point. There is no particular magic in the layout except to keep the signal flow in one direction. The circuit does have a lot of gain, but no difficulty with oscillation was encountered. Just keep the output portions of the circuit from being routed near the preamplifier input. Signal flow is from right to left in the photo of the circuit card. U1 is in the lower right-hand corner of the card and U3 is in the lower left-hand corner. The three large parts to the left of U1 are capacitors for a 120-Hz notch filter that was deleted from the circuit. They are not required and are not indicated on the processor schematic. The voltage regulator chips, U3 and U4, are mounted to the circuit card. This arrangement provides sufficient heat sinking for the power dissipated at input voltages up to 15 volts.

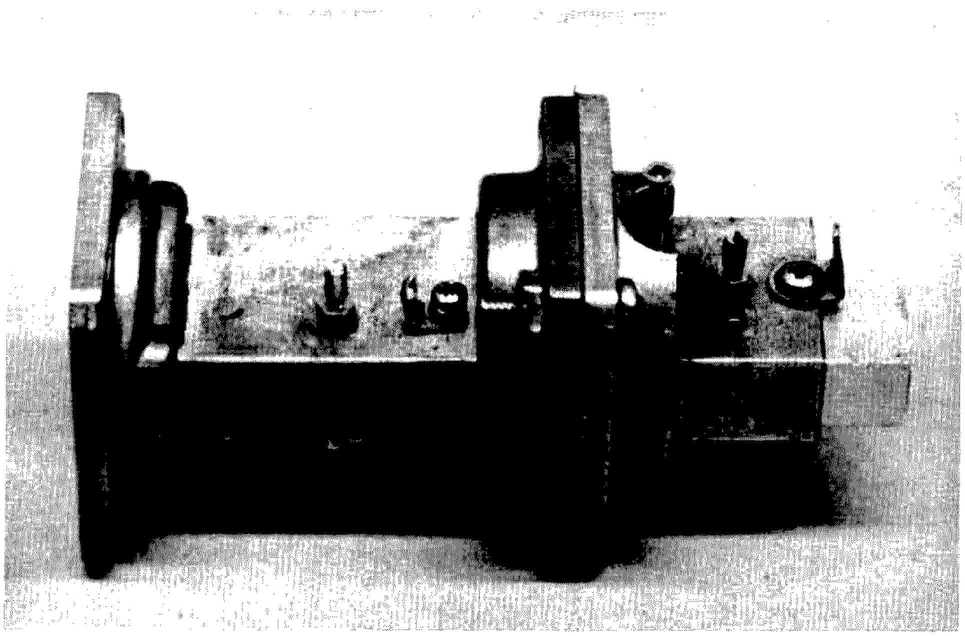

Photo F. X-band transceiver breadboard. The X-band transceiver was developed by adding a simple "diode in the guide" mixer assembly to the breadboard oscillator. The coupling iris is clamped between the mating waveguide flanges.

The output from the Doppler mixer is connected to the processor input at terminals T5 and T6. Shielded cable is used to prevent noise pickup. The mixer diode on the X-band transceiver has an output terminal and a ground terminal. A 10k resistor should be connected from the output terminal to ground. This serves two purposes: It provides a dc return for the Doppler mixer and it serves to ensure discharge of the coupling capacitor, C1, in the Doppler-processor preamplifier. The output terminal of the mixer is connected to input terminal T5 on the processor via the shielded center conductor of the input cable. The ground terminal on the mixer is connected to T6 on the processor with the coax cable braid.

The connections to the mixer from the preamplifier should be made prior to final installation of the mixer diode. This is done to reduce the danger of diode burnout during the soldering operation.

The Gunn-diode oscillator portion of the X-band transceiver is powered from terminal T7, the 7-volt output of the processor voltage regulator.

Doppler Radar Operation and Test

Some initial testing of the Doppler processor may be performed independently of the X-band circuitry. This is useful to isolate any problems with the processor.

After checking the wiring, apply 12 to 15 volts dc to the processor supply input terminal, T3. Load the +7-volt regulator with a 50-Ohm, 1-Watt resistor. This will draw 140 mA from the oscillator supply and will simulate the Gunn-oscillator load. Measure the +7-volt regulator output. It will not be exactly 7 volts. Adjust the select in test resistor, R24, to obtain 7 volts within a tolerance of plus or minus 250 millivolts. The voltage at the output of the +10-volt regulator should be checked and will be pretty close. 9.5 to 10.5 volts is acceptable. Voltages less than 9.5 will cause performance of the op amps to degrade. If all is well, the voltage at the emitter of Q3 will be just about 2 volts. If this is the case and the 10-volt supply is wrong or inoperative, the problem is with U3. If both supplies are wrong, the problem is with U4 and Q3.

Once the dc supply is operating, the rest of the circuit may be tested. When power is first applied, the large capacitors, C3 and C4, must charge. U1 will be inoperative for about 20 seconds, so do not worry if things don't work immediately after power-up.

Apply a 20-Hz audio signal to the preamplifier input. Use plenty of attenua-

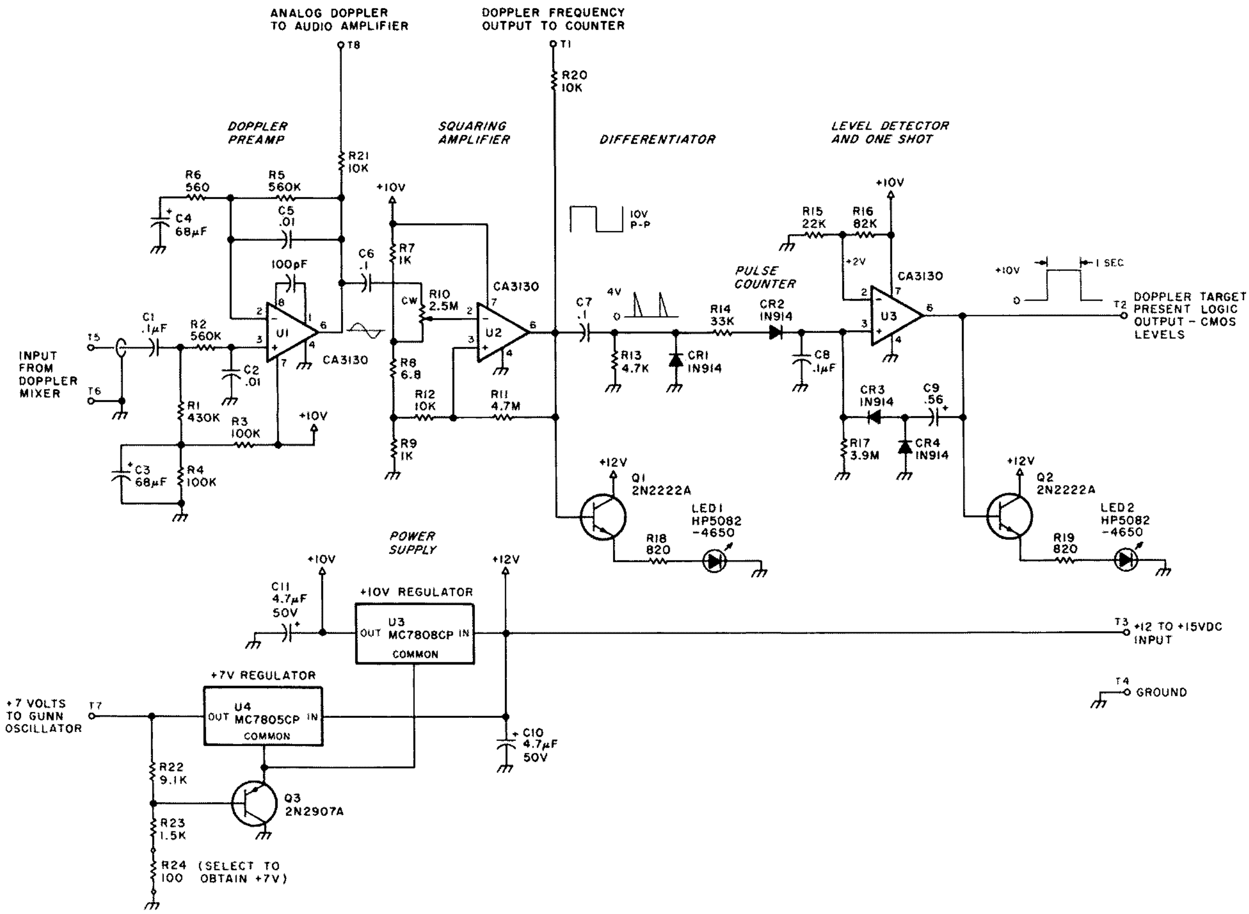

Fig. 12. Doppler-signal processor schematic. This circuit provides a 10-volt CMOS-compatible logic output when a Doppler return is received. The output stage will provide up to 2 mA of output current to an external load.

tion. 50 or 100 microvolts rms should be sufficient. U1 has a gain of 1000 (60 dB) and will easily provide the 50 millivolts of input required to drive U2 to full output.

Increase the input to U1 until 50-100 millivolts is obtained at test point T8. Set R10 for maximum sensitivity and check for a square wave at terminal T1. The amplitude should be 10 volts peak-to-peak.

At this point, LED indicator 1 should be illuminated. Removal of the audio input or a decrease in gain adjustment will cause the LED to go out. If it remains on, check to see if pin 6 of U2 has returned to ground. If pin 6 is at +10 volts instead of ground, then there is a problem in the input bias/offset circuit of U2.

With the square wave present at T1, a series of sharp pulses should be observed at the junction of C7 and CR1. The pulses should be positive-going and have an amplitude of several volts. The pulse will be in phase with the positive edge of the squaring-amplifier output. A small negative-going pulse will occur in phase with the falling edge of the square wave, but will be clamped to −0.8 volts by CR1.

If all of this is working, then U3 will have decided that a target is present and will have a +10-volt output at T2.

Remove the audio input. T2 should go low in a few seconds. Apply the audio input. T2 will go high in about 2 seconds. If the voltage at pin 3 of U3 is observed on a scope or very high impedance meter, it will be seen to rise slowly upon application of audio input. If the input is removed prior to reaching the +2-volt threshold, it will be seen to decay as R17 discharges C8.

If the 2-volt threshold is reached, the monostable trips and the voltage at pin 3 will jump up to nearly 8 volts as the positive feedback is coupled from C9 via CR3.

LED 2 should be illuminated whenever a signal has been applied for more than 2 seconds.

Upon completion of testing, the processor may be operated with the X-band transceiver. When first connecting the transceiver to the processor, be sure to observe the cautions with regard to connection of the mixer diode. Do ensure that C1 is discharged and make the mixer-diode connections with the diode removed from the mount or with the mount shorted. Also, be sure to check for oscillation of the Gunn-diode supply regulator. I encountered no difficulty as long as the .1 μF capacitor and 33-Ohm resistor oscillation suppression network was used at the Gunn-oscillator power terminals.

Place the unit in operation and connect a scope to T8 and a dc VTVM to pin 3 of U3. Walk in front of the waveguide output and observe the Doppler waveform on the scope. The dc voltmeter will indicate the charge and discharge of the pulse-counter circuit. LED 1 will blink whenever there is motion and LED 2 will be illuminated when enough Doppler cycles have been counted to give an alarm indication.

For these tests, the open-ended waveguide is sufficient antenna. The gain is about 5 dB. A range of 10 feet or so will be obtained with this antenna.

The Doppler frequency may be counted by connecting a frequency counter to T1. Use a gate time of one second. The count accumulated will be the total number of Doppler cycles averaged over the one-second interval. Observation of the scope will confirm that the Doppler waveform is complex and is not a single frequency.

The processor output is a CMOS-compatible logic level that goes from 0 to +10 volts when a target is detected. In my application, CMOS logic was used to process inputs from a number of sensors. The output may also be interfaced directly with other devices. The CA 3130 output stage will source or sink 5 milliamperes, which is sufficient to drive an output buffer or relay driver for higher current loads. Fig. 13 is a suggested buffer for loads of up to 2 Amperes.

If the radar is to be used as an intrusion detector, set it up for a couple of weeks in the intended location. Connect an electromechanical counter to the output to record false alarms. This will permit optimization of the sensitivity setting and installation without creating a lot of bothersome false alarms. The circuit has plenty of sensitivity and will see a person at up to 100 feet with a 20 dB gain antenna.

Avoid installations which look directly at a street. Autos have a large radar cross section (as most of us know by now) and are detected at a greater distance than people. What you definitely do not need is a noisy device which informs you that your neighbor is backing out his car!

The unit may be installed in a wood cabinet and will work right through materials such as one-quarter-inch paneling or plywood. Wallboard and plaster attenuate the signal and tend to mitigate the effects of passing autos if the unit is properly positioned.

Antennas

I use a small horn having a length of 2.5 inches and an aperture of 2.3 and 3.0 inches. This is not an especially good horn design from a sidelobe standpoint, but it serves the purpose. Horns are easy to make and have the advantage that their gain and beamwidth are easily calculated. You can make a horn which will almost exactly cover the area to be protected.

Conclusion

In writing this article, I have tried to inspire interest in X-band microwave projects at several levels. The theory of Gunn-oscillator operation and a basic oscillator design are there for those who want the "how-to" information to build one into a communication system of their own design.

The X-band transceiver presented is far from an optimal gadget (especially in terms of noise figure), but it does provide a simple and inexpensive vehicle for experimentation in both X-band communications and Doppler radar. I would like to see someone mount two transceivers at the focus of a pair of 3-foot dishes and have a QSO or two. A number of years ago, a friend sent fast-scan TV over a 1000-foot path using a similar arrangement. By adding attenuators at the receiver, a 10-mile path was simulated with good results. X-band offers plenty of opportunity for TV experiments and for truly secure command links for repeaters.

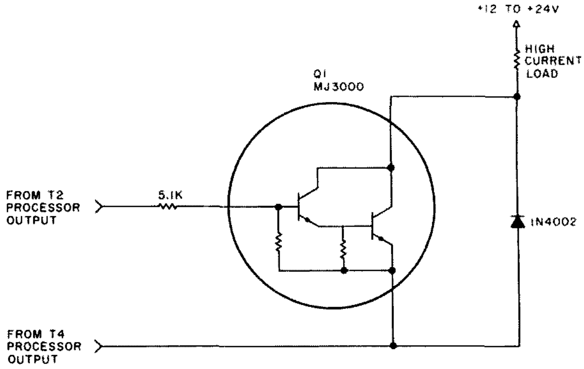

Fig. 13. High-current driver. This circuit uses a high-current Darlington power transistor (Motorola MJ 3000) and will boost the output capability of the Doppler processor such that loads up to 2 Amps at 24 volts may be driven. The diode is to prevent inductive kickback damage to the transistor if inductive loads are connected. The two unlabeled resistors are included on the monolithic Darlington chip.

Doppler radars are interesting projects in themselves. The Doppler processor presented in this article is a practical design I developed to deal with real intruders. Two such units have been in operation for several years with satisfactory results. I am sure that someone will find other uses for this handy form of motion detection.

This article would not be complete without a word with regard to the "radiation hazard." Much has been written of late which alleges a "microwave radiation hazard." A lot of this is uninformed speculation. It has been known for years that microwaves (and lower-frequency rf) cause heating of tissue and that high-power sources such as radars are hazardous.

A major difficulty occurs in attempting to extrapolate the observations for short exposure to high-power sources to long exposure to low-power sources. At present, the permissible level for *continuous* exposure to microwaves or low-frequency rf is not known. Certain standards have been proposed (10, 1, or 0.1 milliwatts/sq. cm) in an attempt to be super safe until more data is accumulated.

Conservative standards are one thing. The real question is this: What precautions should be observed in amateur microwave activities? I apply the same rules that I have used and observed as a working microwave engineer in industry for the past 15 years. They apply equally to microwave projects as to your 2 meter kilowatt. Do not stay in situations of high-power density for long periods. Do not stare into the output of a waveguide source for any period of time at short distances. The level falls off rapidly with distance and is negligible beyond several inches for low-power X-band sources. Remember that a high-power VHF transmitter is equally hazardous if you insist in holding the antenna or standing within a wavelength of it. Time is also a factor. The low-power density recommendations assume exposure on a continuous basis. This is seldom the case in a hobby activity. In short, use common sense.

I hope that this article has provided a starting point for some interesting projects. I will look forward to hearing from anyone who either builds the equipment or who has further questions. ■

Legalized ASCII! The Quad-S System!

—even the FCC approves

At last.

Editor's Note:

Ed Sommerfield W2FJT developed this clever techinque for sending ASCII signals via SSTV back in 1977. Naturally, there was some doubt as to the legality of the scheme, since Section 97.69 of the FCC Rules and Regulations permits only five-level (Baudot) radio teleprinter signals. Ed began a long correspondence with the FCC concerning his development, and in October, 1978, his efforts finally bore fruit. Below is an excerpt from a letter dated October 12, 1978, written to George Enuton of the FCC's Personal Radio Division:

> **Regardless of the type of information transmitted under this scheme, the actual modulation of the transmitter and subsequent transmitted signal is classified as an F5 emission and legal for transmission in the amateur service, subject to the . . . restrictions (of Sections 97.61 and 97.65).**
> **(signed) John A. Reed**
> **(approved) Julian T. Dixon, Chief, Research and Standards Division, FCC**

For reference, Section 97.61 is the table of authorized frequencies and emissions while Section 97.65 deals with (among other things) the bandwidth of F5 emissions.

So here we have it: a technique for transmitting ASCII on the ham bands which carries the FCC stamp of approval. Now, let's get some systems on the air.

E. H. Sommerfield W2FJT
49 Spring Road
Poughkeepsie NY 12601

The FCC does not permit amateur radio Teletype™ transmission of other than five-level Baudot start/stop code. I have not been able to find any restriction, however, on the content of an SSTV picture. Of course, alphanumeric characters are presently being sent via SSTV. These characters are formed by many lines of white/black information, which is the same method I am using to transmit ASCII.

The problem with the existing SSTV character transmission system is that, although displayed characters are easily interpreted by humans, they are absolutely not interpretable by another machine, be it a computer, TTY, or otherwise. A need exists today, and that need will grow tomorrow, to transmit 8-level binary and ASCII data. Nothing in the present FCC rules, however, says that binary or ASCII cannot be translated into single lines on an SSTV picture and sent as FSK video.

This article describes how I translated 8-level ASCII code into crystal-controlled SSTV pictures. Also described are some easily-achieved transmission standards.

Overview

The Quad-S (Slow Scan Start Stop) adapter was designed to accept a character of up to 8 bits (byte), from sources such as an 8-bit Teletype™ or microcomputer, and to translate these bits into a single line of an SSTV picture. The picture is transmitted via FSK (Frequency Shift Keying) FM, line by line (character by character), and detected by either a standard SSTV monitor from which the binary signal can be extracted, or by a microcomputer cassette interface modified for the appropriate mark and space frequencies. Use of

	Frequency	Duration
Horizontal sync	1,200 Hz	greater than 5 ms but less than 30 ms
Vertical sync	1,200 Hz	greater than 30 ms
Maximum white	2,300 Hz	
Maximum black	1,500 Hz	

Table 1. SSTV standards.

fb/20,480 (÷ 16 ÷ 16 ÷ 16 ÷ 5)	= 15 Hz line freq.
fb/8	= 38,400 Hz
38,400 Hz/18 (÷ 9 ÷ 2)	= 2,133 Hz mark
38,400 Hz/24 (÷ 12 ÷ 2)	= 1,600 Hz space
38,400 Hz/32 (÷ 16 ÷ 2)	= 1,200 Hz sync
fb/2,048 (÷ 16 ÷ 16 ÷ 8)	= 150 Hz serial-out (10 bits)

Table 2.

the recovered binary data depends upon the application. In my application, the binary data was fed into a special UART for computer processing. A block diagram of my ASCII/SSTV transmitting system is shown in Fig. 1.

Generating the Transmitting Signals

The selection of SSTV modulating frequencies was determined by the following factors: 1. Are there existing standards? 2. Can crystal control be applied? SSTV satisfies the first requirement; reasonable standards do exist. See Table 1. Now that we know the range of frequencies from which the sync, mark, and space frequencies can be chosen, let's examine two ways controlled frequencies can be generated.

A vco (voltage-controlled oscillator) requires adjustment. A crystal oscillator does not require adjustment. I selected the crystal method since not all readers have the necessary equipment for precise frequency adjustment. The basic crystal frequency selected was 307,200 Hz, which we will call fb. The various frequencies derived from fb are shown in Table 2. All frequencies except 2,133 Hz and 1,600 Hz are derived from repeated divisions by 2, and therefore will be locked in phase with the 150-Hz serial-out clock. Both mark and space can be viewed on any SSTV monitor, and this can be helpful for signal checking.

Now that the mark, space, and sync frequencies have been assigned, let's discuss duration. We're going to use one of the crystal subfrequencies to define the number of pulse groups per SSTV line. At least eight are needed for a binary byte. The nearest exact crystal subfrequency for this purpose is 150 Hz, or ten times the line frequency of 15 Hz. Thus, the SSTV line time of 66.66 ms will be divided into 10 equal segments of 6.66 ms. Since we only need eight segments, the

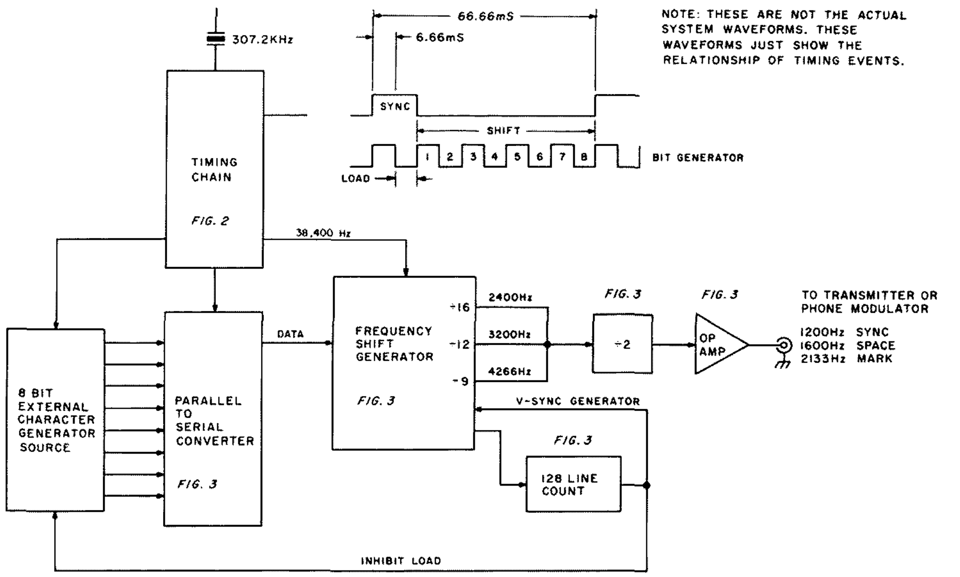

Fig. 1. Overview of the transmitting system.

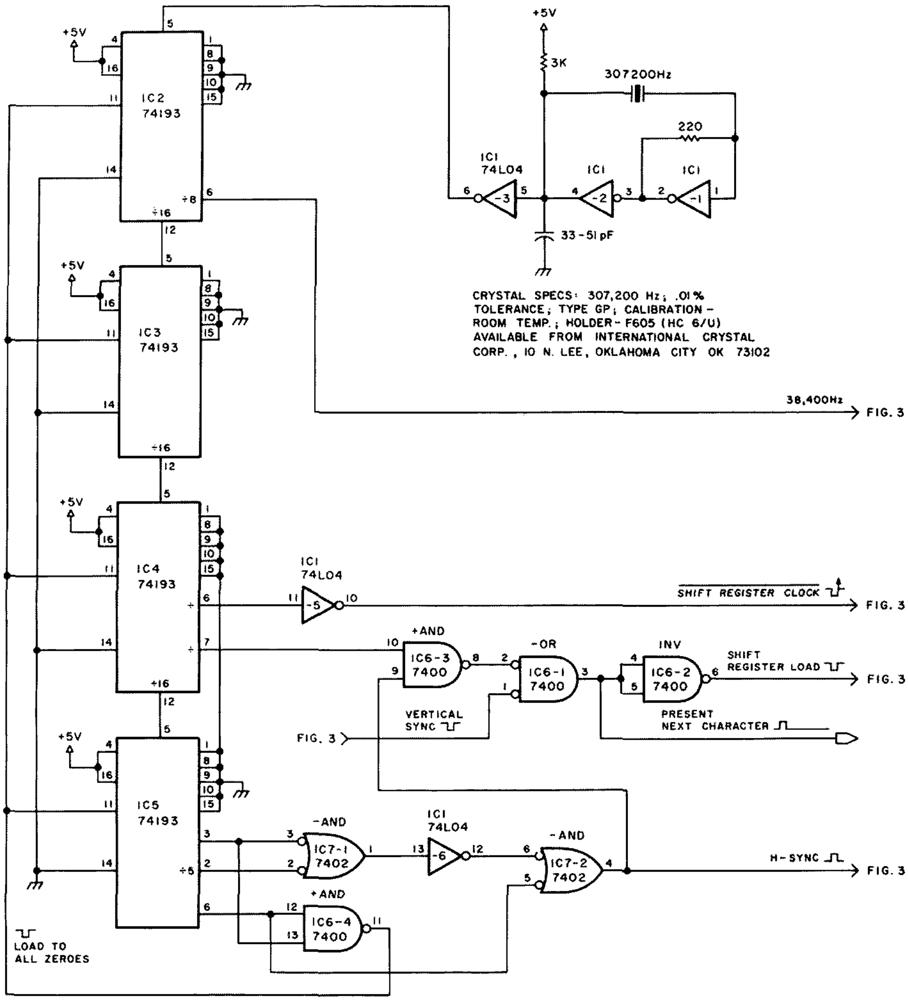

Fig. 2. Transmitter bit-timing chain.

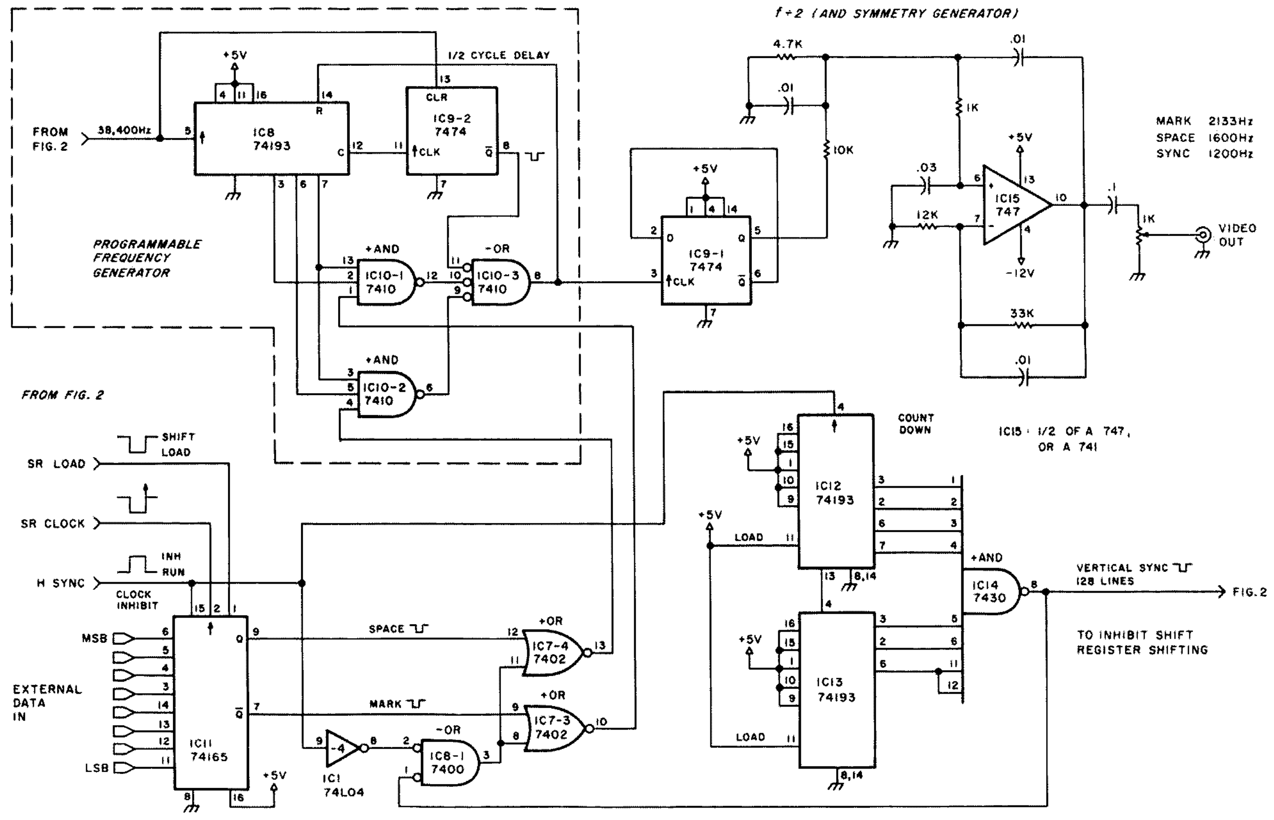

Fig. 3. Transmitter signal and V-sync generator.

other two (13.33 ms) will be used for sync.

Here's How It Was Done

Instead of the usual point-by-point logical description, which is an excellent cure for insomnia, I'm going to describe logical functions. The functional diagram will show notes as to which detailed logic blocks are included in each function.

IC1 (Fig. 2) is a free-running 307,200 Hz crystal oscillator, and is the basic timing source for the transmitter. IC1 drives a complex countdown timing chain consisting of IC2-IC5. An output at 38,400 Hz is used to drive a programmable frequency generator IC8, IC9, and IC10 (Fig. 3). The timing for this function is shown in Fig. 4. The output frequencies of this generator are divided by 2 by IC9 to provide a symmetrical output signal at 2,133 Hz for mark, 1600 Hz for space, and 1200 Hz for sync. IC15 is a bandpass output amplifier/driver with a cutoff of about 3.0 Hz.

Another pair of outputs, described by timing waveform rather than frequency, are obtained from IC4 and IC5 to provide the bit timing logic signals for the parallel-to-serial converter.

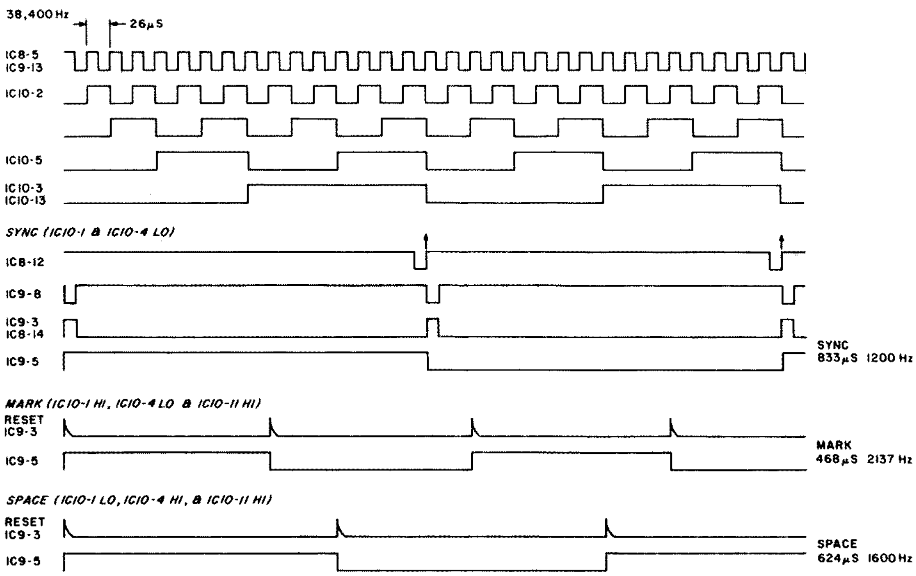

Fig. 4. Programmable frequency generator waveforms.

Signal Conversion and Frame Definition Logic

Control of the timing chain is based upon a 66.67 ms line and an 8 second, 128 line frame. Let us refer to a typical line sequence and its significant timing points (Fig. 5) and line events. The sequence is as follows:

1. Horizontal (H-sync) begins.
2. The parallel-to-serial shift register is loaded, but not shifted out.
3. H-sync ends.

4a. Signals are shifted out of the parallel-to-serial shift register. These serial signals are applied to the variable-count timing gen-

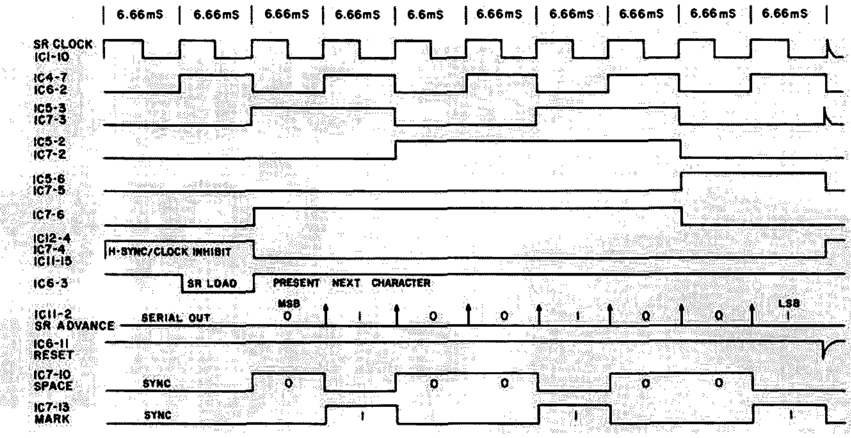

Fig. 5. Significant transmitter timing waveforms.

erator (IC8-10) to generate an FSK FM signal.

4b. While signals are being shifted out, a control line is made active to the external source to present the next character. Vertical sync (V-sync) is generated when IC7 pin 10 (Fig. 3) is held low by IC14 pin 8. This causes a continuous sync frequency of 1200 Hz to be transmitted. Pin 10 is allowed to go low for 67 ms to generate a V-sync pulse. At the beginning of each line, IC12 and IC13 are decremented. When 128 countdowns are reached, IC14 provides a negative pulse to IC7 pin 10 (through IC8) and a vertical-sync pulse is generated. During V-sync time, IC11 is held in a load state. Its bits are not shifted out until the beginning of line 1.

Test Configuration (Fig. 6)

In order to test the system, a binary pattern consisting of ASCII characters @A-O was generated by temporarily connecting the vertical line counter, IC12, to the low-order data input bits of IC11. The high-order bits of IC11 are fixed at 0100. Thus, the repetitive pattern shown in Fig. 7 consists of:

0100	0000
0100	0001
.	.
.	.
.	.
.	.
0100	1110
0100	1111
0100	0000

The FSK output (Fig. 7) was tested by viewing it on a standard SSTV monitor, recording it on an audio cassette, and then playing it back through the same SSTV monitor. This was done in order to ascertain whether the bit time lengths were sufficient to accommodate variations in tape recorder speeds.

Modifying the Original Design

After using Quad-S for a time, it became apparent that certain changes could be made to the hardware that might make it possible to use a UART at a later date. Also, changes to the format of the frame could be made to make it easier for the receiving station, including the FCC, to determine the nature of the data being sent.

By Quad-S line definition, we will always send a fixed line format of 10 bits that will be designated as shown in Fig. 7. In order to make it easier to detect errors when data is received, the data is put together in a manner so as to be self-checking. In other words, one part of the data is used

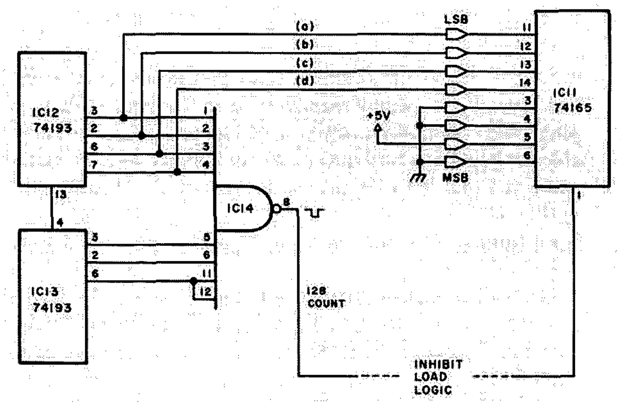

Fig. 6. Test generation hardware configuration.

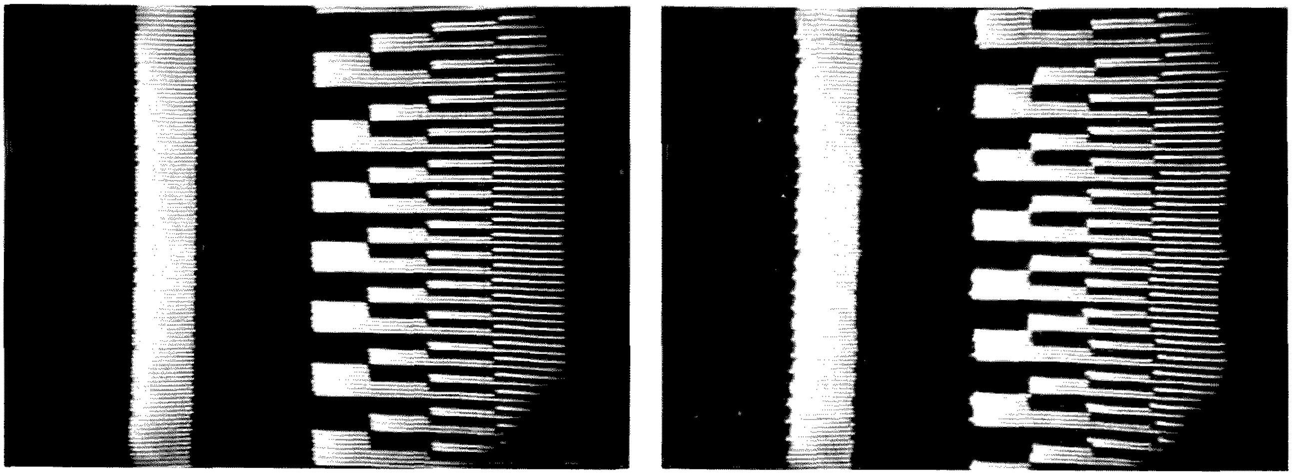

Fig. 7. FSK output as viewed on an SSTV monitor. Photo at left shows Quad-S transmitter output to cassette tape input. Photo at right was produced from cassette tape output. Both photos show SSTV FSK uppercase ASCII @A-O (40-4f hex.).

to check the other part. There are many ways to do this; one easy way is the parity method. Error detection via parity states simply that the sum of all "1" bits (bits at the "1" level) in a word must *always* be either even or odd (see Fig. 9). Even is defined as 0, 2, 4, 6, or 8 bits. Odd is defined as 1, 3, 5, 7, or 9 bits. The choice of even or odd parity may appear to be optional, but odd parity is actually the better choice for the following important reason: If no bits are received, this would be equal to a bit sum of 0—even. Even parity demands that the sum of all "1" bits, including the parity bit, be even. 0 bits *is* even and is also an error condition which would pass the test for good data. Odd parity, on the other hand, demands that the sum of all "1" bits, including the parity bit, be odd; 0 bits is even and therefore is an error condition that would always be detected. How do you make the *sum* of all bits which are sent odd? Refer to Fig. 9. Notice that if the sum of all bits, not including the parity bit, is even, uppercase ASCII letter "A" for example, then the parity bit is turned on to make the sum odd. Conversely, if this sum is already odd, uppercase ASCII letter "J" for example, then the parity bit is left in the off condition to retain an odd sum. Thus the sum of all "1" bits in a word is always odd for odd parity. The sender must generate this parity bit through the use of either hardware (74180 module), or by programming, if a microprocessor is used. The other important hardware specification is that the lsb (*l*east *s*ignificant *b*it) will immediately follow the sync bit on each line. If there are only 7 bits, as in ASCII, then the lsb will follow the sync bit and there will be 1 bit position open (usually forced to zero) just before the parity bit. This line format is shown in Fig. 8.

These changes will, of course, require some method of frame format

GENERAL LINE FORMAT	HOR SYNC (1200Hz)	LSB DATA	LSB +1	LSB +2	LSB +3	MSB -3	MSB -2	MSB -1	MSB DATA	PARITY	
UPPER CASE ASCII A	HOR SYNC (1200Hz)	1	0	0	0	0	0	1	0	1	3 BITS (ODD)
UPPER CASE ASCII J	HOR SYNC (1200Hz)	0	1	0	1	0	0	1	0	0	3 BITS (ODD)
VERTICAL SYNC	VERTICAL SYNC 1200Hz FOR ONE ENTIRE LINE										

Fig. 8. Quad-S line formats.

VERTICAL SYNC ALWAYS PRECEEDS HEADER LINE	VERTICAL SYNC 1200Hz FOR ONE ENTIRE LINE										
FRAME HEADER LINE	HOR SYNC	ACK	LSB COUNT	LSB +1	LSB +2	LSB +3	MSB -2	MSB -1	MSB COUNT	PARITY	
LINE COUNT =19	HOR SYNC	0	1	1	0	0	1	0	0	0	3 BITS (ODD)
LINE COUNT =15	HOR SYNC	0	1	1	1	1	0	0	0	1	5 BITS (ODD)
ACKNOWLEDGE TRANSMISSION ACCEPTED	HOR SYNC	1	0	0	0	0	0	0	0	0	1 BIT (ODD)
ACKNOWLEDGE TRANSMISSION REJECTED	HOR SYNC	0	0	0	0	0	0	0	0	1	1 BIT (ODD)

Fig. 9. Quad-S header formats for both transmission and acknowledgement.

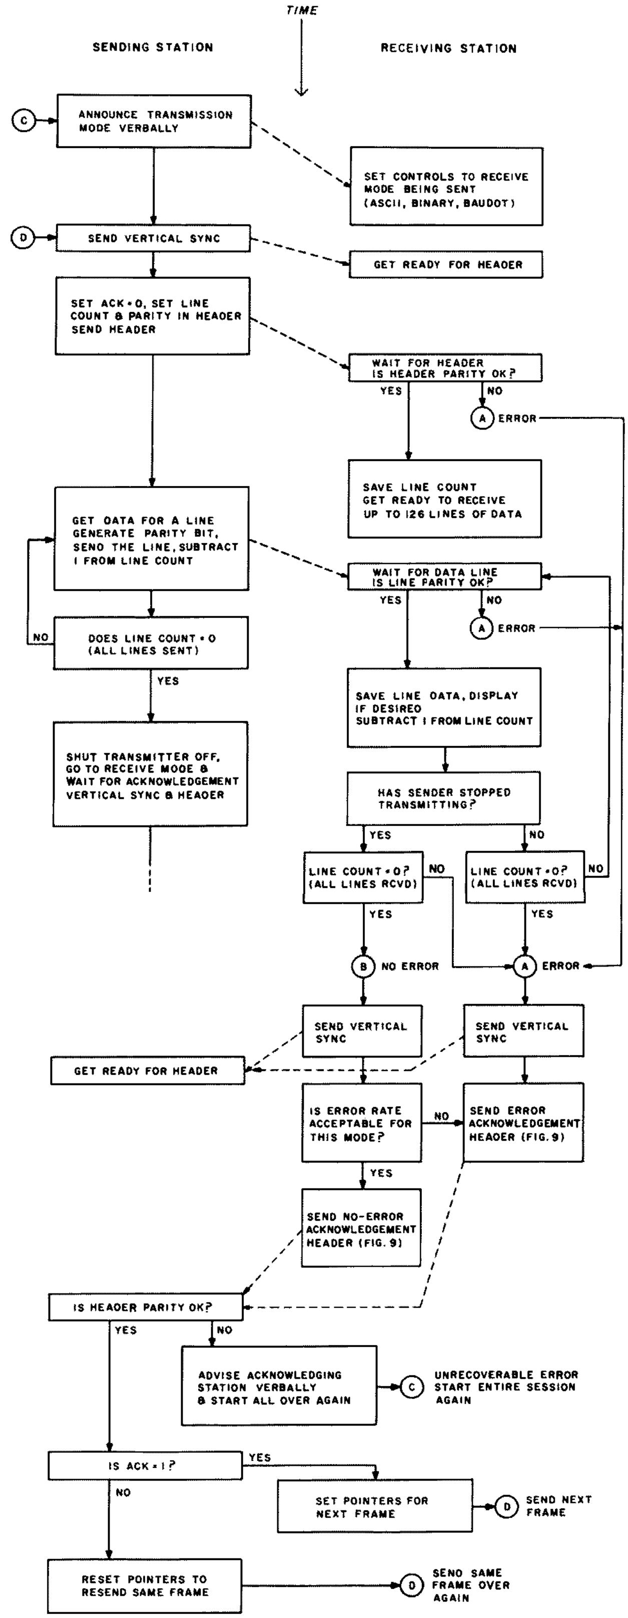

Fig. 10. Suggested Quad-S handshaking sequence for header, data, and acknowledgement.

designation to convey to the receiving station what length code we are sending, and some indication of the number of lines that are to be sent, or when the last line has been sent. This is necessary for the receiving station to properly interpret the data being received. It must know the number of significant bits in each line being received—for example, 5-bit Baudot, 7-bit ASCII, or 8-bit binary. In practice, this information need be conveyed to the receiving station only once before the start of any session, or when the mode is being changed. This information can be sent orally or included in each frame. The receiving station must also know the total number of lines to be sent, or have some indication of the last line, in order to determine, for error-checking purposes, if all of the data has been received. The "end" designator method, unfortunately, does not indicate a line count to the receiver, so missing lines could go undetected. The method that I prefer, due to its simplicity, is a verbal announcement of the mode before starting the session, and including a header line indicating a line count as shown in Fig. 9. This header is easy for the receiver to locate, since it is always sent immediately following a vertical sync pulse frame separator. The line count must be in the range of 1 to 126 (it does not include the vertical sync or header line). This is a count only of the data lines that follow the header line. Notice that in the header, the bit immediately following the horizontal sync bit is called ack (Fig. 9).

Fig. 10 shows a typical data transfer sequence. Note that when the receiving station gets the entire transmission, determined by the header line count, it counts the number of errors (bad lines or missing lines), and if this number is less than the error rate suggested for the particular mode (0% for binary, and up to 20% for Baudot or ASCII), then the receiving station transmits back to the sending station a positive acknowledgement. This is done by sending a vertical sync pulse followed by a header with ack = 1 and line count = 0 (Fig. 9).

This probably should be repeated a few times in case of off-tune conditions. If the error rate is determined to exceed the suggested values, then the header sent back should have ack = 0. When this occurs, the sending (originating) station can retransmit the data. Fig. 10 shows a typical sequence.

I am presenting these "handshaking" conventions primarily because they are simple and easy to implement. I would hope that further improvements could be made as the Quad-S mode of communication becomes more widely used.

Conclusion

I have described what Quad-S is, and detailed how it works. Now, here is why I think that it's better than the regular start/stop code:

1. Quad-S has an unambiguous sync pulse to indicate the start of a character.
2. Quad-S provides crystal-controlled mark and space signals.
3. Quad-S signals can be visibly debugged using a standard SSTV monitor.

It is my hope that the material presented in this article will provide a foundation upon which to build more sophisticated and reliable communications systems. ■

Brew Up a Beam for Two

—double-barreled design

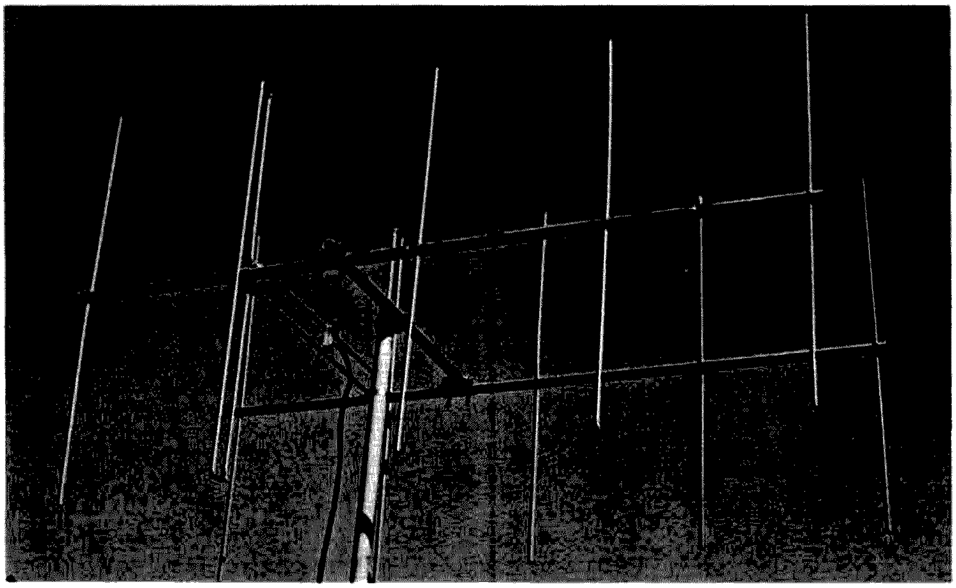
Just what you've been looking for.

Glenn Crowe VE3BSM
RR #5
Wallaceburg, Ontario
Canada N8A 4L2

Here is the 2 meter beam you have been looking for. It has the gain, directivity, and simplicity that put it in a class by itself. No cut and try, no tuning, it has a 300-Ohm feedpoint, or you can use 50-Ohm cable with the balun at feedpoint with the same low swr. The pattern is such that there is one lobe in front with no other side lobes.

It was rugged enough to stand 3 inches of ice with no ill effects during last winter's ice storm. There are many of these in use in this area. I have two pairs of these up at 50 feet, the top pair vertical, and 40 inches below, another pair horizontal. With my IC-22 I have worked a great many DX stations on 2 meters in the last five years. In this area, there are many repeaters and many on the same frequency, so it is important to be able to work the one you want and not bother the others.

Photo by Elmer Hamilton



I recently made checks with the antenna you see in the picture, taken in Sarina, Ontario, 35 miles away at the VE3SM QTH. It is up 38 feet, and the front lobe read 20 over 9; the ends of the elements on me were S1 while the back was S4, so that would make the gain about 30 dB. Stan is using an IC-22S with 10 Watts out.

Ordinary hand tools are all you need to make it up. Use plated bolts and nuts, and aluminum for the brackets. The U-bolts are from Radio Shack, and the booms and elements are from old TV antennas. The cross boom is ¾-inch aluminum conduit. The insulators are ¼-inch clear plastic. I use Belden

feedline UHF no. 9085. It has low loss even when wet, and I put the balun at the transceiver. It is quite broadband with the center at 146.52 and works either lower or higher with very little difference in swr.

I have a similar pair of 4-element beams that I take camping with me, with four sections of masting that go together with thumbscrews. It all goes in the trunk of my car. They, too, give me excellent coverage on the 2 meter band. So spend a few hours and get one together; you'll like it. ■

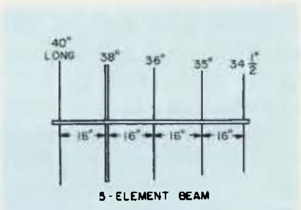


Fig. 1. The 5-element beam (2 required) with about 13 dB gain.

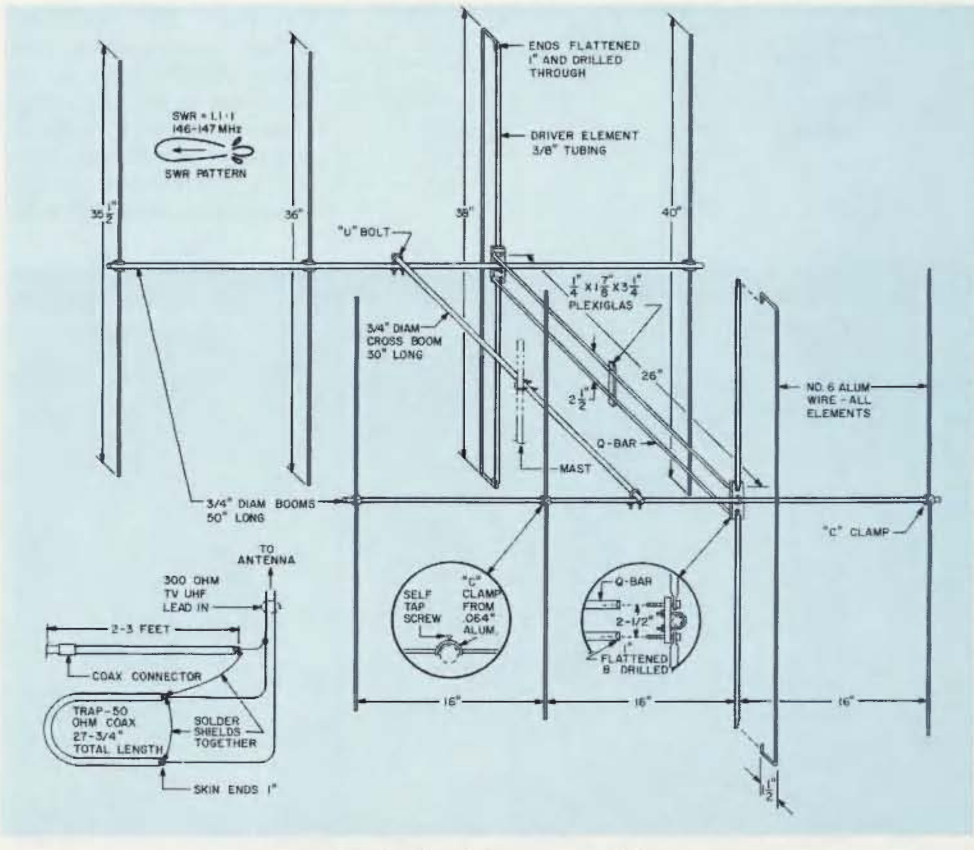

Fig. 2. The 4-element model.

Keyboard Serialization

—when parallel isn't enough

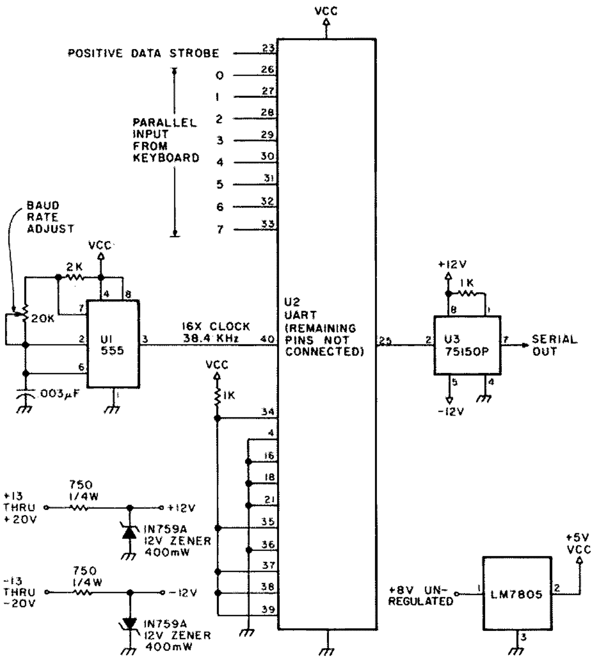

Fig. 1.

Here's a project that you can throw together with three chips and that you will find useful if you have more serial input ports than parallel ones. It will also solve a few software hassles for you if you've been feeding your VDM or TV typewriter with parallel bytes because programmers always seem to expect you to do it serially.

When I found myself with those two minor problems, I decided to build a simple parallel-to-serial converter to take advantage of an unused serial input port. The resulting project was finished that same evening at a cost of about ten bucks, including connectors, wire, solder, and parts. I think this project is simple and useful enough that a lot of hobbyists may want to use it to break into hardware. I think you'll find it painless.

Take a look at the schematic in Fig. 1. As you see it, this is a minimum implementation which could be complicated quite a bit. For the purposes of this article, I decided to eliminate everything but the bare necessities and leave the fun of designing frills like repeat keys, flashing lights, and spelling corrections up to you. The values on components are pretty flexible, but, as shown, will work at 2400 baud quite nicely. For a detailed understanding of the circuit, it's probably better for you to look up the individual chips in a manufacturer's catalog than for me to take up space for the simple theory here.

When you get the circuit built, you will have to hook it up to a power supply providing +18 to +20 and −18 to −20 volts, and adjust the pot for the desired baud rate. If you don't have a scope, you can do it by the trial and error method, but don't be too disappointed if you don't finish the same day you start out! The RS232 level output is what most serial input ports expect, but verify this step before hooking it up. If you want some other kind of output level, a different chip will have to be chosen for U3.

That about does it! Now . . . let's see what we can do with that spare parallel input port . . . ■

Reisterstown MD 21136

Ignition Noise and 2m FM

—one ham's cure

Peace and quiet come to the 280Z.

Recent frustrations with radio noise prompted me to write this article. After purchasing my 1976 280Z, I set about installing a 2 meter FM transceiver. Upon completion, it was observed that a great deal of noise was picked up when the engine was running (except when receiving the strongest of local stations). The intensity and frequency of these noise pulses are directly proportional to engine speed. Since resistance-type spark plug wire has been used in the engine compartment, and reception on the Z's AM-FM radio is clean, you'd hardly expect such a problem, especially since FM reception has a natural noise rejection advantage over standard AM. Regardless, the noise persists!

I began by performing some basic cures. Using short lengths of ½-inch tinned copper braid, the engine was grounded to the body, the tailpipe to the body, and the hood to the body. No help! Next, the coil primary and alternator were treated with filter capacitors. Again, no help. Perhaps the noise could still be coming in through the dc supply line from the car's battery. The radio was then powered by a separate battery. This did not help. Evidently, the noise is radiated through the air from ignition to radio rather than conducted by the dc line. Now a small portable AM radio was used as a detector to sweep over suspected areas such as under the dash, front car exterior, rear car exterior, under the hood, etc. As suspected, the predominant noise source is under the hood. When the hood is closed, noise even leaks through the seams where the hood meets the fenders (and also through the grill and out under the engine).

At this point, I chanced upon an article by the spark plug engineers at GM (AC). It compared various techniques such as resistance plugs, resistance wire, inductance wire, complete ignition shielding, etc. I decided to use resistance plugs in addition to the resistance wire already in the 280Z. Installation of AC plugs (R43XLS) reduced noise somewhat. The combination of resistance plugs and wire does reduce spark slightly, and it is important to keep plugs clean and properly gapped and to check the ignition wire periodically. Otherwise, some missing may be experienced at high RPMs.

The final episode: A friend of mine told me about a certain brand of inductance wire stocked at a nearby store. Information from GM (AC) indicated that improvement would be slight. I bought a model 12-72 ignition wire kit made by C. E. Niehoff & Co. (4925 Lawrence Ave., Chicago, Illinois 60630). They don't make a set for the Z but the 12-72, a V-8 set, can be used. Since the coil wire is too short, a leftover long plug wire had to be substituted. I carefully removed the metal clips from the short wire, cut the long wire about 1½ inches longer than necessary, and, with a knife, ¾ of an inch of insulation was stripped from each end. The center conductor was folded back alongside the rubber insulation. The metal clips were crimped on, and the excess center conductor was removed.

With the R43XLS plugs and the inductive wire, noise has been virtually eliminated in the 2m FM rig (perhaps resistance plugs are no longer necessary). An HF rig, which is AM, may still pick up some noise with this modification, but there should still be a substantial improvement. Let me know how you make out. ■

An 8080 Repeater Control System

—part II: hardware

You're on your way.

Robert Glaser N3IC
3922 Algiers Road
Randallstown MD 21133

The control system is built on a 19-inch rack panel. The touchtone™ decoder and power supply are on the rear of the panel. The tape loop, amplifiers, touchtone pad, and main board are on the front of the panel. The main board is a Vector #169P84-062WE 8½- × 17-inch board. The circuitry is assembled using wire-wrap techniques. I recommend the Vector battery-operated Slit-N-Wrap tool. This permits daisy-chaining connections and is invaluable when wiring buses. Discrete components are mounted using Vector T49 pins. The parts are soldered on the top, and the connections are wire-wrapped on the bottom. The board layout is shown in Fig. 1. The circles in the center of the board are LEDs. The relays are on the right side, and LEDs in series with the relay coils are mounted adjacent to the relays. The oblong objects are printed-circuit-board-mount miniature potentiometers. The left half of the board consists of the microprocessor components. Since the board is built with wire-wrap, most sensible layout arrangements will work, but I present my layout to save you from the head-scratching I did in deciding upon an arrangement.

Every connection to the main board is through standard DIP plugs. This permits wire-wrapping to the connectors on the board. Each of the connectors is 16-pin (except the power connector, which is 14-pin). Fig. 3 gives the pinouts. The dummy sockets permit the repeaters to be placed on the air for testing with no control system.

Bypass capacitors (.1 uF) are placed liberally on the power supply lines. At the power supply connector, 100-uF capacitors are placed on each voltage.

Circuit Description

The hardware consists of

two sections: the processor and related circuitry, and circuitry external to the processor which accomplishes audio and control path switching as well as interfacing to the repeater.

To understand how the system operates, examine the path flow diagram in Fig. 4. All of the switches shown are relays in their relaxed position. There are two types of signals: audio pairs, which are shown as one line only, and dc control lines. Relays are used for switching the audio lines and some control lines. Solid-state replacements could be made, but there is nothing easier to interface than switched contacts. Using relays also prevents many problems due to possible idiosyncrasies of audio balancing, impedances, and levels of different repeaters. (I admit that it does hurt to use the ancient relay.) The feed from each transmitter control shelf passes through the repeater enable relay to the PTT line. The feeds are grounded during IDs. The 150 and 450 relays, when activated, positively isolate the PTT lines and prevent the transmitters from keying. If the LINK relay is closed, the two transmitter feeds are shorted, ensuring that both transmitters are activated simultaneously. The audio pairs are shorted together as well, placing the same audio on both transmitters. When the BLOCK relay is energized, the 150 transmit audio is shorted out. This relay is activated to prevent repeating touchtones.

In normal operation, the CRTALK relay is relaxed. In this condition, the audio and COS lines from the voter are passed to the 150 control shelf. The COS lead goes out to the control circuitry and returns to the control shelf. When the CRTALK relay is activated, the voter is removed from the system and is replaced with the control receiver. When the CRTALK relay follows the control receiver COS, the end result is that the control receiver is given priority over the two meter inputs to the repeater. When voltage is placed on the audio gate line to the control shelf, any audio present on the duplex audio input goes to

the transmitter. When the RUSOS lead is grounded, the transmitter remains on the air.

Next, consider the path to the telephone line. LDR (line direction relay) determines whether audio is being fed into the line or taken from it. Normally, LDR follows the COS signal. When no received signals are present, LDR is off and audio from the telephone line goes into the system. During autopatches, this places the party on the telephone on the air. When the COS goes low, LDR activates and the audio coming from the duplex audio output goes into the phone line. During autopatches, this permits the party on the telephone to hear the transmitting station. The audio fed into the control shelf on the AUD lines comes out on the duplex audio pair when the audio gate is not enabled.

With the local/remote switch in the local position, the touchtone decoder is driven solely by the on-site pad. When placed in the remote position, the touchtone amplifier drives the decoder. If CRTT (control receiver touchtone) is relaxed, the decoder is fed from the duplex audio pair or the telephone line. The path for two meter users is through the duplex audio pair, and for control operators on the telephone line it comes from that source. If PHCR (phone control relay) is activated, the two meter input is isolated from the decoder. If CRTT is on, the control receiver has absolute command over the decoder. From this arrangement, it can be seen that the hierarchy of control access is the control receiver at the highest priority, the telephone next, and the two meter input last. By controlling the logic driving the relays, any of these modes of access to the decoder may be precluded. The touchtone generator injects audio at a point where it can drive both the telephone line and the repeater. The latter permits hearing the processor dialing users' numbers. It consequently also drives the decoder, which is not of any particular importance except that it allows the locally generated tones to be blocked from repeating. It may seem that placing tones on the repeater while at the same time blocking them is a silly procedure. However, the end result is that you hear short blips of tones, pleasing to the ear.

Due to the arrangement of the switching paths, level adjustments must be made in the following order:

1) The audio from the control receiver and the voter must be equalized. Place a meter at the output of the decoder amplifier. Adjust the audio output of the control receiver so that equal tone deviation on the two meter input and the control input results.

2) Adjust the gain of the touchtone amplifier for the required input for your decoder. For the decoder specified, this is about two volts rms.

3) Adjust the gain of the LDI (LD input) amplifier so that tones arriving from the telephone line are of equal amplitude with the other two inputs at the decoder.

4) Adjust the LINE IN control on the control shelf so that proper deviation results when talking through the repeater from the phone line.

5) Adjust the gain of the LDO (LD output) amplifier to the required level of your telephone line interface when talking on two meters.

6) Adjust the output level of the touchtone generator for the required level at the telephone line.

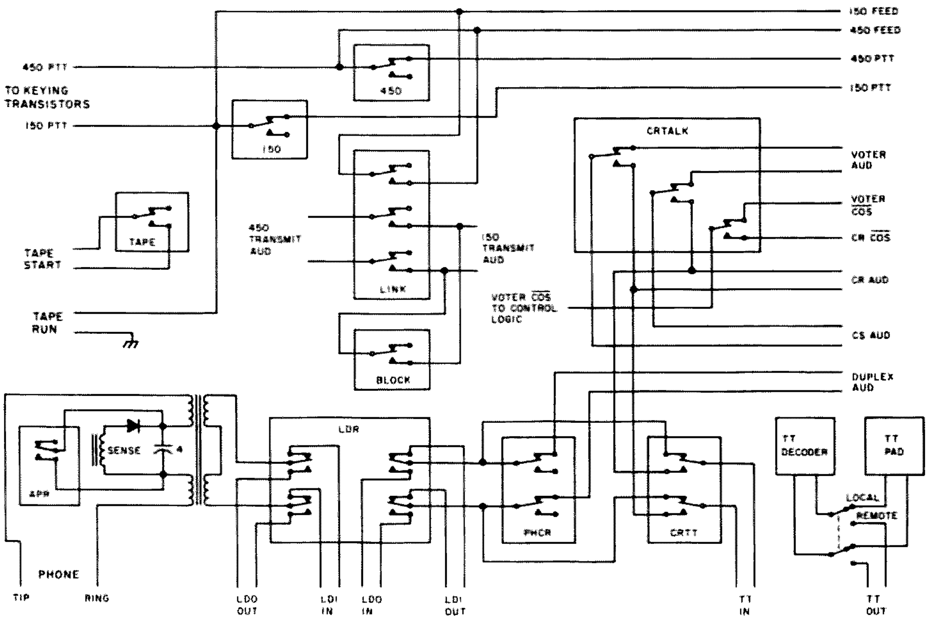

Fig. 5. Relay switching.

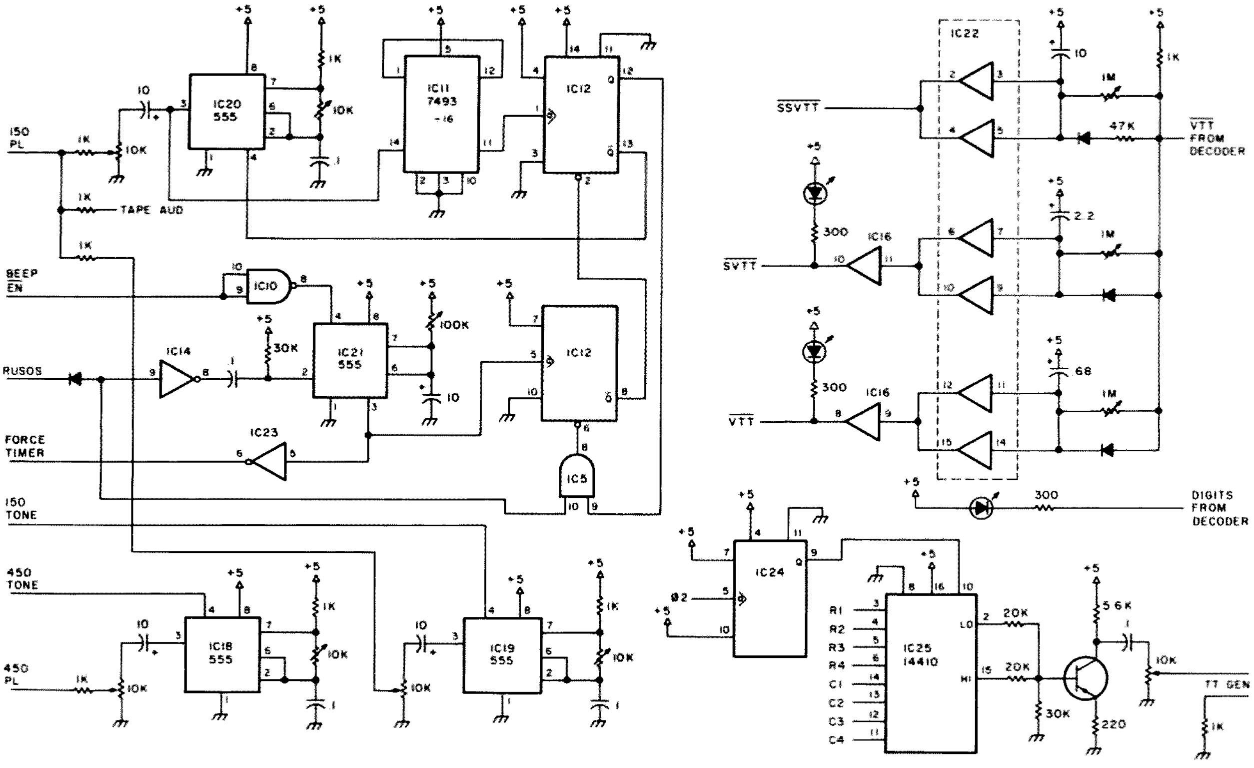

Fig. 6. Audio circuits.

Fig. 5 shows the relay and autopatch connections. Most of the lines go to connectors defined in Fig. 3. The PTT lines from the keying transistors and the voter COS to the control logic are picked up in Fig. 7. The TAPE relay pulses to activate the tape loop. A shorted pair is available from the tape loop while the tape is running and is connected at TAPE RUN. The relay wiring should be self-explanatory.

The autopatch interface circuitry may need to be modified to fit a particular coupler. The line transformer isolates the telephone equipment from the repeater circuitry. A suitable transformer is made for the MASTR line and is available from General Electric (part number 19A116736P1). During an autopatch, APR (autopatch relay) is closed. In our system, the line current is sensed at the other end, and the dial tone is requested. If a coupler is installed at the repeater site, APR may be directly connected to the coupler to request a dial tone. The SENSE relay is a sensitive relay which detects the dc line current. In our system, there is always current present in the line. A quick measurement of line current at the other end ensures the integrity of the line. When an incoming call is made, the line current is reversed. The diode in series with the SENSE relay distinguishes the difference between an idle condition and an incoming call. The SENSE contacts are normally closed and open when an incoming call is made. The contacts remain open until the line is disconnected. This relay is necessary to determine who initiates a call. If a call is initiated from the telephone line, a control access is assumed and PHCR activates. A telephone coupler at the repeater site simplifies some of the circuitry. Any contact pair which opens when the line is in use may be used in place of the SENSE relay, because suitable gating is provided in the control logic to produce the logical equivalent to our system.

The audio circuits are shown in Fig. 6. There are two separate oscillators for the 150 and 440 CW identifier tones. ICs 18 and 19 are simple 555 oscillators. They each have tone and amplitude controls. Pin 4 is the keying input; the 150 tone and 450 tone lines come from the processor output ports. ICs 11, 12, 20, and 21 generate the "beep" tone. Perhaps this is too elaborate an arrangement for such a simple function, but it does provide a distinctive, pleasing sound. It is best described as the "bounce" sound in TV Pong games. It is noticeable, but not objectionable. When the RUSOS lead goes from low to high (carrier release), IC21, a one-shot, fires. The time delay is adjustable and is nominally half of a second. When the pulse falls, IC12 is triggered, placing a low on pin 8. This clears the other half of IC12, putting a high on pin 13, enabling the oscillator, and clearing the first half of IC12. IC20 oscillates and generates the tone. The pitch is variable, and a variety of sounds can be formed by adjustment. The pulses are counted by IC11. At the fall of the sixteenth pulse, the top half of IC12 is set, the oscillator is turned off, and all returns to the rest condition. All of this generates exactly sixteen pulses shortly after the carrier release, providing the "beep" sound. The beep, ID, and tape audio are summed and fed to the transmitter. While IC21 is high, the repeater timeout timer is tricked into believing that the signal is still present. If the user does not wait for the "beep," then the timer is not reset because of the overlapping

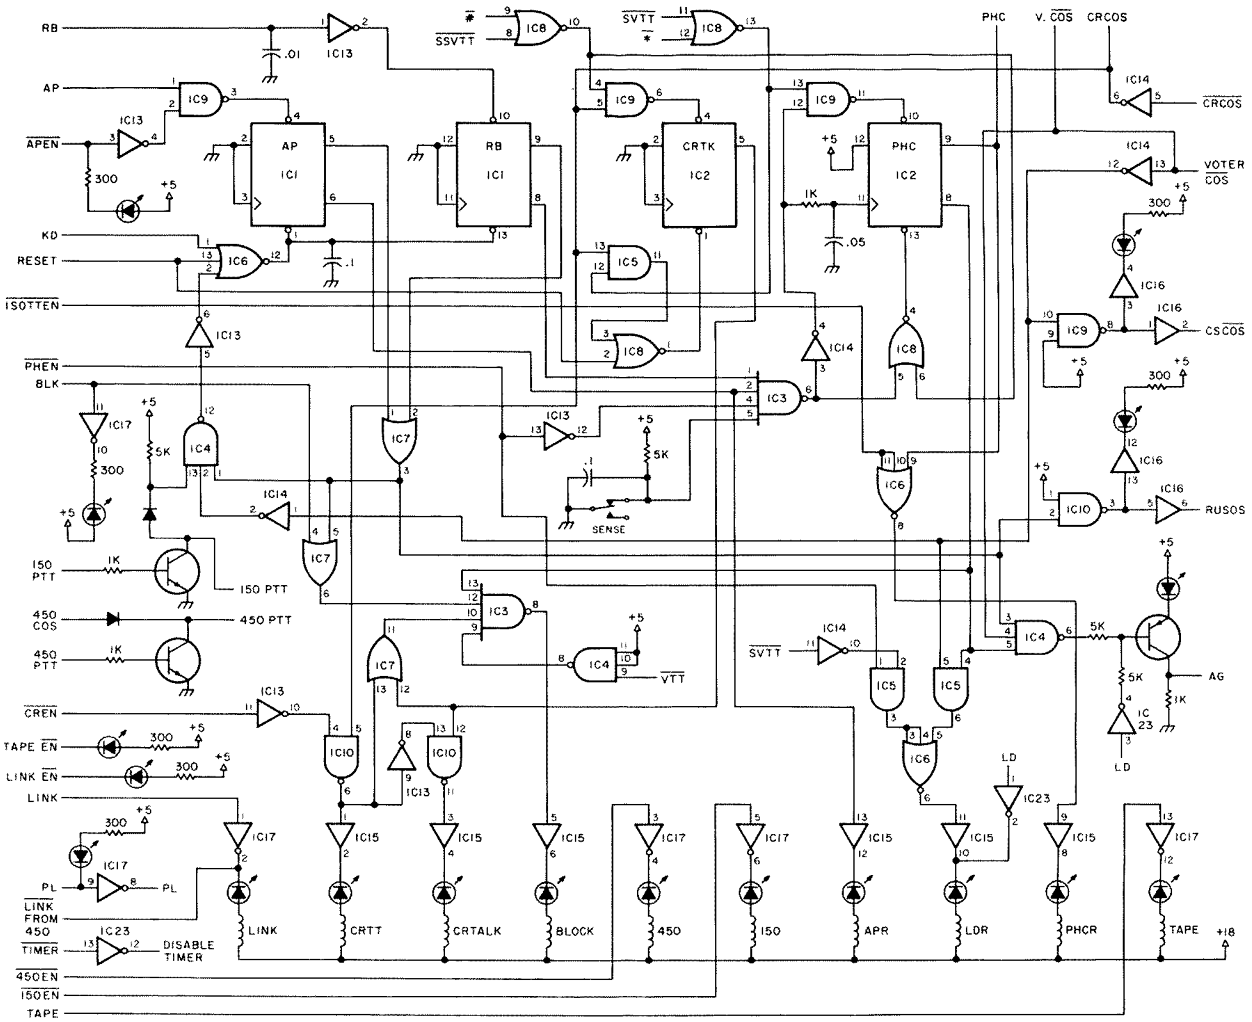

Fig. 7. Control logic.

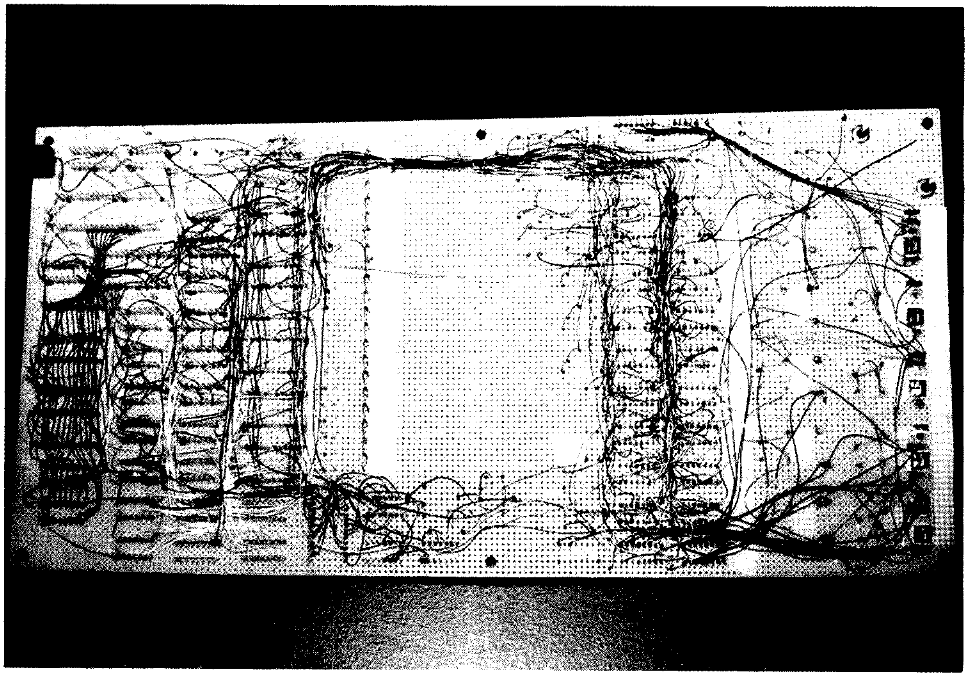

Bottom of board. Reset switch at upper left. Microprocessor circuitry on left.

of the incoming signal and the one-shot. If a signal is present when IC21 falls, then the "beep" is inhibited via IC5. If the beep is disabled, IC21 is prevented from firing by IC10, and carrier release immediately resets the timer. This seems like a lot of trouble to go through for a silly beeper. The system permits a long (3-second) drop delay on the repeater transmitter. In normal QSOs, the transmitter stays keyed continuously, each participant merely waiting for the beep. This saves a lot of wear and tear on the transmitter and amplifier, both of which otherwise are constantly being turned on and off. This is of particular importance for busy repeaters; WR3AFM

logs about 13 hours of uptime per day. The users *do* learn to wait for the beep, leaving time for breakers; if not, they time out.

IC24 divides the master 2-MHz clock by two, supplying the required 1-MHz clock for IC25, the touchtone generator. The rows and columns are selected by the processor at output port #7. The low and high group tones are summed and sent to a transistor amplifier.

Each of the digit outputs from the touchtone decoder has an LED which serves the dual purpose of giving an indication of what is going on and providing a pull-up for input to the processor input ports. The decoder outputs are normally open and go low when active. The VTT (valid touchtone) signal must be processed. IC22, a CMOS buffer, permits high-impedance timer resistors to be used. Each of three sections requires digits to be held a certain amount of time before they are recognized. The VTT output is just a debounced output set for a delay of about 50 milliseconds. The SVTT (slow VTT) output is adjusted for a delay of one second. This sets the amount of time the first digit of 3-digit codes must be held. The SSVTT (slow slow VTT) output is adjusted for 5 seconds. This sets the amount of time required to enter the telephone listen and control receiver talk modes.

The circuitry which performs the switching functions is shown in Fig. 7. The outputs of this section are the relays and the CS COS, RUSOS, AG, DISABLE TIMER, PL, and PTT lines. There are four state flip-flops. The AP (autopatch) flip-flop goes high during an autopatch, and the RB (remote base) flip-flop is high during a remote base operation (reverse autopatch, limited to control operators). The CRTK (control receiver talk) flip-flop may be left in either state, but by operating convention is normally left low. If it is set, any signals coming from the control receiver will be repeated. The PHC (phone control) flip-flop is normally clear and is set when a call-in is made on the phone line. The gating of these flip-flops will now be described.

The clear inputs of AP and RB are driven from IC6. If any of the three inputs to that gate go high, IC1 is cleared. A KD (knockdown) pulse from the processor will do so. When the knockdown digit is received, the processor pulses the KD output high. The master RESET pulse also clears the flip-flops, setting the initial states correctly after power on. The third input comes from an AND gate made up of ICs 4 and 13. If all three inputs of IC4 go high, then the flip-flops will be reset. This input provides for these functions to be killed should the repeater time out. If either function is up, pin 3 of IC7 is high. Whenever these functions are on, the RUSOS lead is grounded to keep the transmitter on the air. If the RUSOS lead is low, and the 150 PTT is high, sensed by pins 13 and 1 on IC4, then the repeater must be timed out. The last input to the AND gate is the voter COS. This only allows the AP and RB functions to be killed from a timeout if the incoming signal is released. During autopatches, if the repeater times out, the party on the telephone hears the last transmission made even after the repeater drops off the air. At that point, all three inputs to IC4 are high, and the function is killed.

The processor pulses the RB input line, setting the RB flip-flop when a remote base function is requested. When an autopatch is requested, the AP input is pulsed. If the APEN (autopatch enable) input is low, IC9 passes the request and the AP flip-flop is set. Otherwise, the patch is not permitted to start. This autopatch defeat is easily done in software, but this method allows visual indication when at the site that the autopatch function has been disabled.

The CRTK flip-flop is set when both inputs of IC9 are high. Pin 5 goes to the CRCOS (control receiver COS), so this can only be enabled by a signal present in that receiver. Both inputs of IC8, which feeds the other input of IC9,

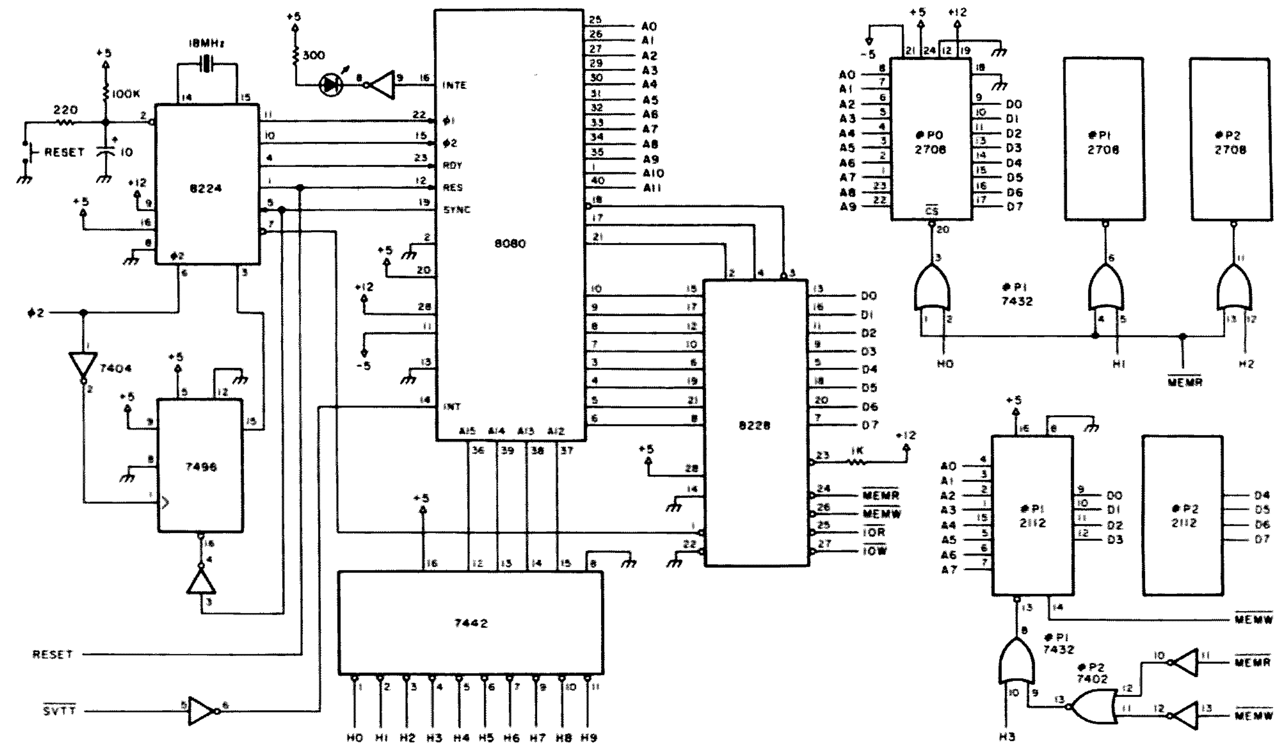

Fig. 10. Processor and memory.

must be low as well. The # digit and the SSVTT signals must be present. Therefore, the # must be held for 5 seconds while transmitting on the control frequency in order to enable the CRTK mode. CRTK is cleared by IC8. The RESET pulse goes to pin 2, clearing CRTK on power-up. Otherwise, the two inputs of IC5 must go high. One input goes to the CRCOS, so it can only be killed on the control frequency. The other input comes from pin 13 of IC8, which goes high when a one second * is received.

The PHC flip-flop is controlled in part by IC3. If any of the four inputs to this gate are low, the output is high, clamping PHC clear through IC8. If telephone loop current is sensed, the PHEN (phone enable) line is low, and neither the RB nor AP flip-flops are set, then pin 6 of IC3 goes low. If the last three conditions are satisfied when a call-in is made on the phone line, the transition clocks PHC high, placing the system into the telephone control access mode. Pin 6 of IC8 is driven from the five-second # gate, so PHC can be cleared in this manner, permitting the repeater input signals to be heard on the phone line. Via pin 13 of IC9, a one-second * sets PHC again.

The rest of the circuitry is combinational. Rather than give a detailed description of how each gate operates, I have shown the Boolean logic functions in Fig. 8, from which the circuitry can be easily understood. The 150, 450, and TAPE outputs are directly driven from the processor outputs. APR is directly driven from AP. The CS COS is a buffered COS output. The CRTT relay is activated if CREN (control receiver enable) is low, and if a signal is received in the control receiver. Normally, this relay follows the control receiver, giving it priority over anything else for access to the touchtone decoder. The CRTALK relay follows the CRTT relay if the CRTK flip-flop is set. PHCR is activated when PHC goes high. If 150TTEN (150 touchtone enable) is high, PHCR is also on. This totally isolates the decoder from two meter inputs.

Normally, LDR follows the COS. If PHC is high, it stops following the COS, giving the control operator total control from the telephone line. Otherwise, whenever an incoming signal is present, the line direction gets turned around, and tones from the telephone never reach the decoder. If PHEN is low, LDR follows the SVTT signal. This is used to remove control access from the telephone line. Every time an attempt is made to send a tone down the line in this mode, the line is turned around, cycling the relays and removing the tone from the system. It is a clumsy but simple way to accomplish the task. The LD output from the processor also activates LDR, to ensure that the locally-generated touchtones produced when redialing a number go down the telephone line.

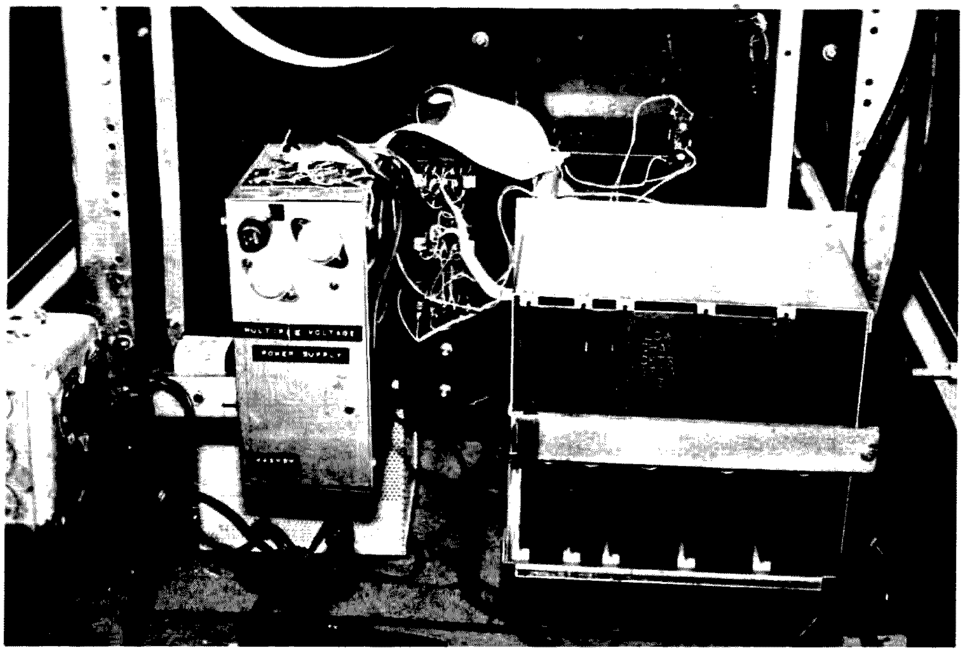
When in the blocking mode, BLOCK follows VTT. To be in the blocking mode, the BLK signal must be present from the processor, or an autopatch or remote base function must be in progress. The blocking mode is left for two special cases: when controlling the repeater on the phone line or the control receiver when it is not repeating. If these exceptions were not made, when a control operator was executing functions, users talking on the repeater would have their voices blotted out every time a tone was sent by the control operator. This would limit control to when the repeater was free. The PHC bar in the BLOCK formula stops the blocking for telephone control, and the CRTK + CRTT bar removes the blocking for silent control on the con-

trol frequency.

LINK normally follows the output from the processor, but a link request from 450 also activates it.

AG is activated during autopatch or remote base functions when the incoming signal is released, placing the telephone audio on the air. The LD output from the processor also activates AG so that the redialing of telephone numbers can be heard on the air. The RUSOS lead is grounded during autopatches and remote base operations.

ICs 15, 16, and 17 are open collector buffers used to drive the relay coils and external inputs. The AG input requires +10 volts. A PNP switching transistor, through an LED which drops a couple of volts, accomplishes this. The PTT outputs from the processor feed NPN driver transistors to keep the transmitters on the air during IDs. The keying transistors should be hefty enough to sink the current of the PTT lines of the particular transmitters used.



Rear of control system rack, showing power supply and touchtone decoder. The amplifier sockets are also visible.

Depending upon the repeater timer control methods used, the FORCE TIMER and DISABLE TIMER inputs may or may not already be present. Fig. 9 shows the necessary

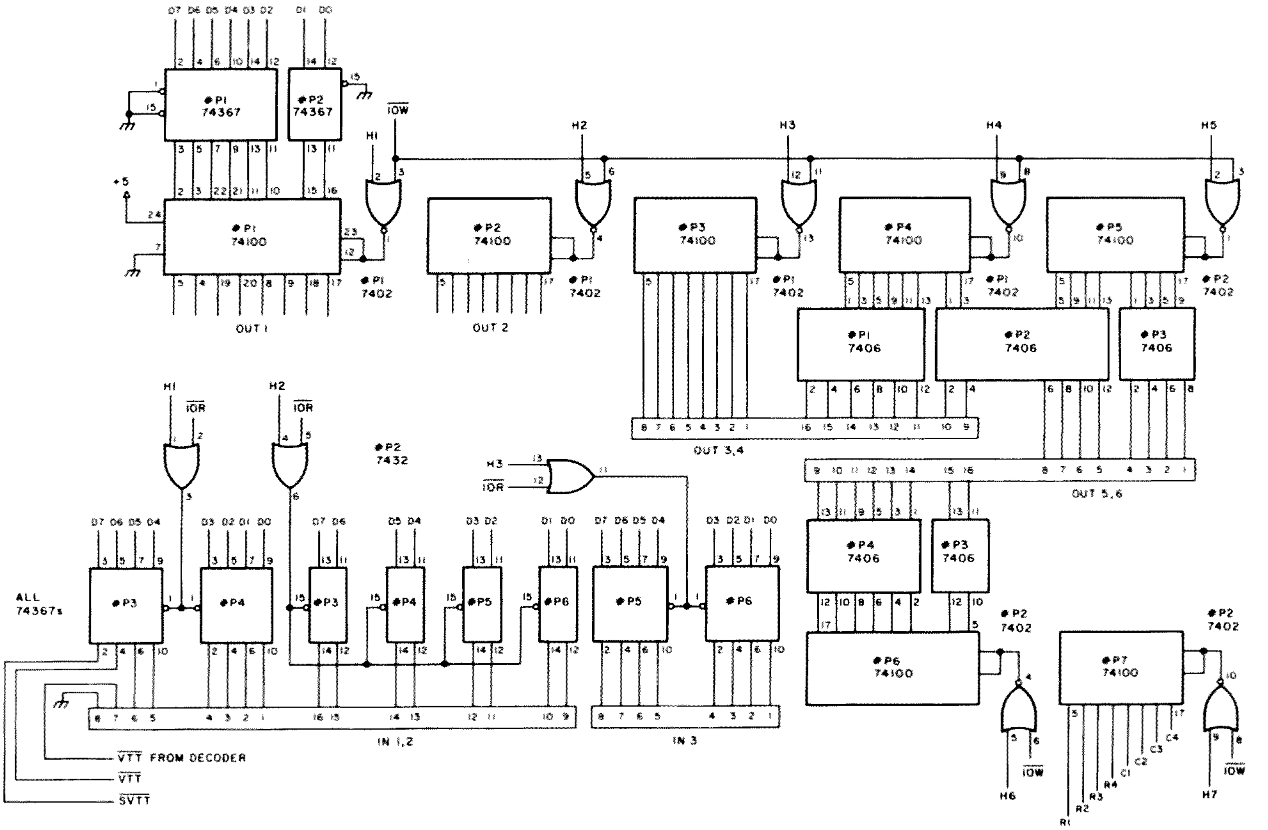


Fig. 11. Processor I/O ports.

modifications if a General Electric MASTR control shelf is used.

The Microprocessor

There are scores of microprocessor chips on the market. Many could be selected as the controlling element in a control system. A single interrupt is required. Barring other considerations, the RCA Cosmac would be a good choice because it is fabricated from CMOS technology, causing it to draw very little current and to have high noise immunity. The major consideration when selecting a microprocessor chip is support. I chose the Intel 8080 family for three reasons: I am extremely familiar with it, I have a supply of spare chips for that family, and I have the needed software support. The software support is most important.

There are a number of memory chips which can be used. I decided to use 2708 ROMs because I have a supply of them and because they are easily programmed. Newly constructed systems would do well by utilizing 2716 ROMs. The 2716 has twice the capacity of the 2708, and in this application, only one is required. The 2716 is even easier to program than the 2708. A minimal amount of RAM is required. Two 2112s, each 256 x 4, are used, providing 256 bytes of RAM.

The microprocessor components are considered separately from the rest of the hardware. The integrated circuits are not numbered, except where more than one of a particular number is used (where the letter "P" is attached to indicate that the IC belongs to the processor). The processor and memory schematic is shown in Fig. 10. The 8224 support chip provides the clock signals to the 8080 using an 18-MHz crystal. It also is the source of the power-up RESET pulse. Pushing the reset switch also generates a RESET pulse. The 7496 shift register introduces one memory wait state. The 8080 has plenty of speed for its required functions, and the 2708 ROMs are cheaper in the 650 ns variety, so a wait state was added so that the slower memory could be used. I suggest that the 18-MHz clock and wait state be retained for duplication, for the simple reason that otherwise the timing loops in the program will have to be readjusted.

The SVTT signal interrupts the processor. There are several reasons for using SVTT rather than VTT. Voices tend to be momentarily detected as touchtone. Using VTT to interrupt the 8080 would result in the processor frequently being interrupted for no purpose. This is bad, because when interrupted it stops counting time and initiates tone blocking, resulting in unintentional blocking of voices. Operationally, SVTT requires the first digit of any code to be held for a second; this gives control operators a chance to respond to unidentified stations attempting to access the system. The INTE (interrupt enable) is monitored by an LED, showing if the interrupt program has been exited, since after exit the interrupt is always re-enabled.

The four high address lines feed a 7442 decoder to provide the memory and I/O port selects. The rest of the address bus goes directly to memory. An 8228 bus controller buffers the data bus and produces the memory and I/O read and write signals. The pull-up resistor on pin 23 lets the 8228 perform the single interrupt instruction.

The program is stored in 2708 1K x 8 ROMs. The addressing is set by the H0, H1, and H2 lines. The ROMs are selected only during a memory read operation. Three sockets are provided for 2708s, and currently only two are needed, leaving room for an expanded program. It is simple to add up to six more 2708s by paralleling all lines and using the H4 through H9 lines. The RAM

consists of two 2112 256 x 4 chips. They are selected during memory read or write operations. On the memory chips, all pins not shown are paralleled with the other chips.

The input/output ports are shown in Fig. 11. 74100s are used for output ports because they are inexpensive. 74367s (8097) are used for input ports and buffers. 74367 #P1 and part of #P2 are used to buffer the data bus from the output ports. The H1 through H7 lines are used to select the port addresses, which correspond to 10, 20, ... hexadecimal port numbers. The input lines for 74100s #P2 through #P7 are paralleled with those lines on 74100 #P1. Output ports 1, 2, and 7 go directly to the rest of the hardware. The port and bit designations are shown in Fig. 12. Ports #3 through #6 go to output connectors. The input ports are as shown. Ports #1 and #2 come from the touchtone decoder, the VTT and SVTT conditioned outputs, and the two repeater COS lines. The decoder plugs into IN1,2. The pins which do not connect to the decoder are left open and wired over to the RPT1 connector. Two of the inputs on port #3 are used, and the remaining six may be used for expansion.

The power supply must provide +5, +12, and −5 volts for the circuitry. Other voltages may be required for your choice of amplifiers, decoder, and pad. Up to 2 Amps is required for the +5 supply, and 1 Amp is sufficient for the rest of the voltages. A power supply schematic is shown in Fig. 13. An LM309 regulator is used for +5, and it works—but this is on the close side. ■

DX Fantasy

—a moment in the sun

What you don't know can't help you.

L. Foord VE3FLE
763 Gladstone Dr.
Woodstock, Ontario
Canada N4S 5T1

It was official: Effective 0001 GMT, all VEs could use the CJ prefix. I relished what lay before me. After years of chasing DX, for the first time (before the world discovered that CJ = VE, a fact that would hardly impress anyone), I would be the chased. Of course, I wouldn't disguise this detail; I simply wouldn't advertise it.

At the appointed hour, I ran to the rig and aimed the beam east. "CQ DX CQ DX from CJ3FLE."

They were there in an instant; the band exploded with Europeans clamoring to work me.

I imitated the best DXer's style I had heard and started to work them: "G2ZZ from CJ3FLE. Fifty-seven."

Back came the reply: "CJ3FLE from G2ZZ. 59, break."

"Roger; thanks for the report. QSL to VE3FLE. QRZ DX from CJ3FLE?"

"CJ3FLE from DL2XX."

"DL2XX, you're 58, from CJ3FLE."

"QSL. Thanks for the contact. What's the QT—"

"—roger, roger. QSL to VE3FLE. QRZ the G-station?"

And on I went. The stations were characteristically weak—they were no doubt in confusion as to where to point their antennas. But I was concerned with giving everyone the opportunity to work CJ, so I kept the QSOs short.

One French station was pounding in. "F2XX, you're 58 from CJ3FLE."

"QSL, you're five nine plus. Nice signal. What's the QTH?"

"Thanks for the report. QSL to VE3FLE. QRZ DX from CJ3FLE?"

"CJ3FLE. What's the QTH, old man? F2XX."

"Oh, sorry old man. We're in Canada. VE-land," I whispered, and then turned the amplifier back on, "CQ DX from CJ3FLE?"

The band began to shift and Asia came rolling in. I was ecstatic. It seemed as if all of Japan were calling at once. What a feeling!

As I worked the JAs, I could hear the stateside stations trying to break. One particular strong W7 kept calling, with such a strong signal I was having trouble hearing the JAs under him.

"W7XYZ from CJ3FLE. Fifty-eight."

"Thanks, old man." He came back sounding very pleased. "Didn't think I was going to get through. Beautiful signal here, even though I know you're beaming north. You're 5 and 9 plus. Name here is Bud."

"Thanks, Bud. Nice signal yourself. QSL to VE3FLE if you want a card ... 73 for now. QRZ DX from CJ3FLE?"

"By the way," it was the W7 again, "is there an award for working that special Canadian prefix? I've already worked a dozen of you and was wondering if there might be a certificate."

I felt crushed. "Ah, no, I don't think so," I replied.

"Okay; 73 and thanks for the contact."

"73. QRZ DX from CJ3FLE?" I said and glanced at the clock—less than an hour had elapsed.

I continued to call for DX but over the next hour managed only a handful of contacts. Finally I shut off the rig and leaned back and pretended the band had folded. ■

Windsor CT 06095

If you must ask yourself, "What would I want with a log periodic dipole array (LPDA)?" then, obviously, you are unaware of the benefits of this amazing antenna. The main advantage of an LPDA is that it is frequency-independent. The gain, front-to-back ratio, swr, and other electrical characteristics remain fairly constant within the design limits.

Unlike a parasitic beam, whose performance deteriorates as the operating frequency is moved away from the design frequency, the array is not tuned to a single wavelength. The array has elements which are resonant at various points within the passband of the antenna. Very simply stated, at a given frequency, there is a group of elements which are near resonance; these act as driven elements. The nonresonant elements in front of the "driven" elements act as directors, and those behind act as reflectors. Hence, the antenna has many combinations of "driven," "directing," and "reflecting" elements.

When faced with the task of designing an LPDA the old-fashioned way, you can look forward to grinding out the numbers with pencil, paper, and calculator. It can be very boring and time-consuming. If you are not fortunate enough to get the results you require on the first attempt, your only alternative is to repeat the entire tedious process. However, in this age of microcomputers, you have only to type in a few numbers, wait a few seconds, and, miraculously, out pop the element lengths and spacings for your LPDA.

After examining the program, the results should seem a little less miraculous. An antenna can be designed in one of two modes. In both modes, you enter the frequency limits and two constants. In mode one, the computer will calculate the number of elements and their lengths and spacings. In mode two, you may also enter the number of elements. The computer will then design an antenna with these specifications.

This program is tailored to work on almost any computer processing BASIC which is equipped with higher math and radian trig functions. If optimized for your computer, the program can be condensed considerably. It was written on a Digital Equipment PDB 8/e minicomputer. For all inputs, yes is one, and no is two.

To use mode one, you must enter the higher and lower frequency limits (lines 190-220). You must also input the two constants tau and sigma (lines 250-300). Tau must be in the range of .8 to .99, and sigma must be in the range of .05 to sigma optimum (sigma optimum is equal to .258 x tau = .066). If you answer no to line 310, the computer will calculate the values for an LPDA with the characteristics which were entered. If you answer yes to line 310, you may enter a specific number of elements. If possible, the computer will optimize the constant tau for the highest gain and the smallest array with the characteristic input. If no antenna can be designed for the values encoded, you will be blamed for entering unacceptable data (line 590).

After the computer has sweated over the figures, it will print out boom length and number of elements (lines 730-740). You are then able to either accept these and get a printout, or reject them and change the inputs (lines 750-780). Just enter the number of each item to be changed (lines 680-700). The entire process will repeat itself, and you will soon be staring at a new set of data. How easy can designing an antenna be?

All of the computations are performed on lines 360-580. On line 360, the cotangent of alpha is

C = cotangent of alpha
D = length of element
P = spacing of element
B = operating bandwidth (should be approximately equal to F)
F = upper frequency over lower frequency

Table 1. List of variables.

calculated. Line 370 computes the bandwidth of the active region. The length of the boom is calculated on line 380. If the number of elements is predetermined, lines 490-580 will optimize tau for any given sigma. The loop increments tau by .001 at each pass and checks to see if the results are acceptable.

The element lengths and spacings are listed with lines 810-880. After listing these items, you are allowed the choice of continuing or packing up the inch-thick pile of printouts you already have and going off to begin work on your antenna. Now that you have enough data to design a thousand antennas, you can choose the one best suited to your needs.

The log periodic dipole array is a truly versatile and useful antenna. And, since one is so utterly simple to design, you have no excuse not to type in this program, punch in a few figures, and prepare for the construction of your personal, computer-designed LPDA.■

New Coax Cable Designations

—watch for them

Upgraded standards since 1977.

Carl C. Drumeller W5JJ
5824 NW 58 Street
Warr Acres OK 73122

For years, ever since the Hitler War, radio amateurs have placed their trust in coaxial cables bearing RG- designations. For good cause, too, as they were manufactured to strict military standards. As of 15 March 1977, a new set of standards was introduced and made mandatory. This new standard closes some loopholes in the former specifications.

Most manufacturers of coaxial cable turned out products of which they could be justifiably proud. Some scrimped. Even the best products were made to specifications that unwittingly omitted important factors. Now, though, all such cable made to current requirements, as spelled out in MIL-C-17E, will have certain additional desirable characteristics.

For instance, cable approved under MIL-C-17E will have tightly controlled adhesion between inner conductor and dielectric. If you've ever had, in cold weather, the inner conductor contract enough to pull back the male prod on a type N connector, you'll appreciate this requirement!

In another pair of specifications, the outer jacket must have dimensional stability. It must not shrink back from a connector, nor may it crack and pull away from the shield when stressed.

How do you spot the new and desirable cables? Look for the stamped-on identification. For what used to be RG-58C/U, for instance, look for M17/028-RG58. Note carefully that there is no hyphen between RG and 58.

Incidentally, I did not find a new version of the old stand-by, RG-8/U. It must have been replaced by one of the new three-numeral series.

Cable marked with the old designations still will be manufactured. Be thoroughly aware, though, that it very probably will not be of the high quality that characterized such cable when it was made to military standards. In fact, already some quite inferior cable is being sold. It looks like the "real" thing; it's the same size and of the same exterior appearance. When rf is piped into it, it's quite another matter. It may leak rf like a sieve; it may have high attenuation per unit length; it may have "suck-out" points. "Suck-out" points are narrow frequency bands at which the cable displays very high attenuation although passing other frequencies with only nominal attenuation.

So, if you want the best, look for (and pay dearly for) the newer MIL-C-17E series of coaxial cables. Keep in mind that a penny saved on coax cost may be a dollar lost in precious rf dissipation. ■

The Micro Magic Pi Designer

—figure networks with a minimum of fuss

A bulletproof program.

Gil Boelke
505 Main St.
West Seneca NY 14224

Here's a BASIC program to design pi-networks, used for impedance matching and filtering. A feature of the program is that it makes a smooth transition to the degenerative case of minimum Q—the L-network.

When the primary function is to transform impedance with minimum loss and not to provide filtering action, the L-network is the way to go. For a given impedance ratio, it provides the broadest bandpass of any resonant network, and the lowest loss.

If filtering action is required, such as for harmonic rejection, or if the impedance ratio is to be made variable through the use of variable capacitors, a pi-network may be better. Q may be chosen as desired and a range of impedance ratios can be accommodated without changing the inductor value. A pi-network is nothing more than back-to-back L-networks. Since an L-network always steps impedance either up or down, a pi-network can be used to provide filtering action with equal impedances at both source and load, as well as transformations up or down. If the two L-networks have equal ratios, the first steps impedance down and the second one steps it back up to the

same value.

In each L-network, the transformation ratio increases with higher Q values. For a Q of zero, the component values diminish to zero; thus the program specifies a piece of wire as the answer to this problem!

When you give it a problem, it always calculates the minimum Q required to do the job. (Remember: The lowest Q is the lowest loss and the least critical in parts values.) If you need a higher Q for filtering action, you simply enter it. On the other hand, if an L-network is desired, just enter "MIN" and the computer will use the value it already has, saving you the trouble of re-entering it.

It then prints out the circuit and gives parts values. Afterwards, you have a chance to change the frequency or the impedance ratio, or to enter a new problem before leaving the program.

An effort was made to "bulletproof" the program by filtering out negative values and divide-by-zeros and by providing for the accommodation of impedance values without regard to whether the first is greater or less than the second. The schematic always labels the impedances of each port so you don't get them mixed up.

The program was written for MITS extended BASIC with multiple statements per line, plus some functions such as "PRINT USING" and "SWAP," but these are easily purged for running it on other BASICs.

Finally, my apologies to those who have much memory in their system. The statements are not separated by spaces for those who do not! ■

A Better Micoder™

—no more battery woes

Good-bye to mushy audio.

If you are one of the many who own a Heath HW-2036 synthesized 2 meter rig with the Micoder™, here is a way to eliminate that 9-volt battery for good. Not only is the modification simple, but you end up with a much lighter microphone along with an end to those embarrassing moments when you hear, "Your audio sounds real low and kinda mushy." Here's how to do it:

1. Open up the microphone case and remove the case from your HW-2036. Locate both ends of the black wire in the mike cable (one end goes to terminal 1 on the terminal strip inside the mike and the other end goes to terminal 2 on the three-terminal strip inside the rig) and clip them free.

2. Clip out the battery connector inside the microphone and remove it. The red wire should be removed from pin 5 of SW101 and the black wire comes off terminal 1 of the two-terminal strip.

3. Solder the free black wire inside the mike to pin 5 of SW101.

4. Solder a 270-Ohm resistor to the wire (WHT-ORG) going to C515 on the vco assembly. The resistor should be soldered to the WHT-ORG wire near the ferrite bead.

5. Cover the resistor and leads with spaghetti or some other insulating cover and connect the free end of the resistor to the free black wire inside the rig. After carefully checking that all leads are properly insulated, put everything back together and get back on the air. ■

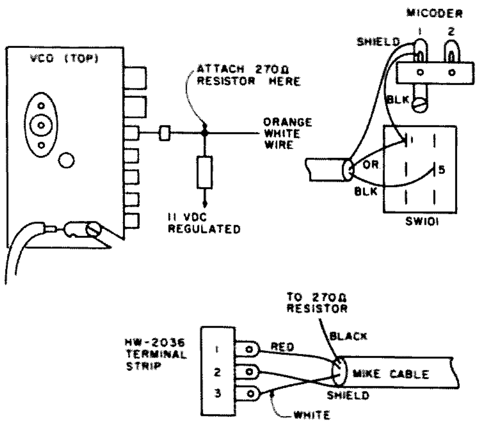

Fig. 1. After modification. It doesn't matter whether the shield goes to pin 1 of SW101 or to the terminal strip, as long as both pin 1s are tied together.

Winning the QSO Name Game

—sure beats 3 x 5 cards

Put your info on the tip of your tongue.

Charles E. Thomas WA3MWM
7022 Blackhawk
Pittsburgh PA 15218

Would you like to have a fantastic memory with everyone's name on the tip of your tongue (keyboard)? Whether you are running for office, trying to borrow equipment, or just want to appear to be on the ball, this program will fill that need.

The number of newcomers appearing on the repeater scene increases every day. It is extremely difficult to remember everyone's name. Using my program, all you have to do is type in the call of the operator. The computer supplies you with his call and his name. A small piece of information can be included if you so desire.

I wrote this program using SWTPC 8K BASIC to run on my 6800-based machine. Southwest BASIC reserves 32 bytes for a string variable. This would allow 6 bytes for the call and 1 byte for a space. This leaves 25 spaces (bytes) available for the operator's name and a key word of information pertaining to that particular operator. If your memory is small, you might consider limiting the length of the string variables by adding DIM statements.

String variables in Southwest BASIC may be named any single alphabetic character or a subscripted letter. The subscripts permitted are 0 through 9 only.

Program listing.

When adapting my program for your own use, be sure to keep some type of line number organization to avoid confusion when adding new calls to memory. Assuming you are using the program for local 2 meter operation data, the call area will probably be the same for the majority of the entries. Therefore, concentrate on the last three letters of the operator's call. In my program, I assigned the line numbers as follows: 100-190 to the calls whose last three (or two as the case may be) letters begin with the letter A, 200-290 to those whose last three letters begin with the letter B, and so on through the rest of the alphabet. Those amateur calls contained in statement lines 100-190 would be assigned the string variables A$(0) through A$(9). Those in lines 200-290 (beginning with B) would be assigned B$(0) through B$(9) and so on. Line 9000 is inserted as a slight delay loop.

A New Approach To Nicad Care

—*charges up to ten at a time*

Is this going to be cheap? How about $1.75 for the two components required, besides the usual transformer, rectifier, and filter capacitor needed for any charger? Is it perfect? Connect any reasonable number of nicad cells (0-10) between the charging terminals, and the current will vary only a small fraction of a milliampere. The design is so simple that I think my brother-in-law could handle it.

Fig. 1 shows the schematic. The circuit and design data are given in the National Semiconductor *Voltage Regulator Handbook*, available at Radio Shack stores. Don't rush out and buy the book for this information, though. Herewith I will save you $2.25 on the cost of building your charger. Besides, using the data in the book requires a lot more time and measuring than using the cut and try system, if you have some idea of just what you are doing.

Your dc supply will have to furnish the following: the maximum voltage of the bank of cells you will want to charge and the rated voltage of the voltage regulator you will use plus its dropout voltage. Figure on approximately 30 volts for use with 10 nicads, but don't forget that the maximum you can use with the voltage regulator is probably 35 volts. Also, when using a voltage regulator, you must watch $I(V_{in} - V_{out})$, the power dissipated in the regulator. With a nominal 1 Amp regulator and the current you will draw, there will be no problem here.

I use a small power transformer rated 25.2 volts at .3 Amps, a silicon diode rectifier, and a 220 uF filter capacitor. Under the load you will use, the voltage is 31 volts. With R1 at 300 Ohms, the charging current is 45 mils exactly, when charging anything from one to ten cells. The transformer gets pretty warm, but not too warm. Everything else gets just barely warm. If you intend to charge at 100 mils, use a larger power transformer — everything else can be the same. I suppose you could incorporate a pot and a meter to make an adjustable-rate charger, but be sure to use a limiting resistor if you do use a pot in place of R1. I use a 220-Ohm shunt across the 300-Ohm R1 for a couple of batteries that can use a 100 mils charge. The transformer has to be "heat sinked," too. ■

Parts List

T1	25.2 V at 0.3 Amp (Radio Shack 273-1386)
D1	1 Amp silicon rectifier
C1	220 uF, 50 V (Radio Shack 272-1045)
VR	12 V at 1 Amp (Radio Shack 276-1771)
R1	selected to adjust charge rate (in the 300 Ω range for 0.05 A)
M1	suitable for charging rate desired (optional)

On the Razor's Edge

—it could happen

Hams, home-brewing, and hamburgers.

Ike Rodman W5WY/1
PO Box 19, Station No. 2
Amherst MA 01002

On a country hillside outside Oklahoma City, George in one tree and Jerry in another tugged a dipole antenna up between them. Besides the two young men in the trees, other signs that this was a weekend could be seen in the distance where, although it was 8:30 in the morning, light traffic moved along the interstate highway—a few cars and a short caravan of army-green trucks. The day seemed to portend nothing headier than a satisfying hilltop QRP contact. The sun would not be too warm, and the breeze not too cool.

The boys were classmates. George was WD5XZF, and Jerry was an unlicensed CBer. George wanted to convert to real radio. From the center of the antenna, a length of coax dangled to the ground near their bicycles. In the basket of George's bike, wrapped in a cloth for protection, nestled an HW-8 transceiver which he was going to demonstrate to Jerry, and a pair of lantern batteries to power it.

The boys were so engrossed in centering the antenna between the trees so no leaves would touch the wires that they did not notice a black limousine leaving the road down at the edge of the field and starting up the grassy hill trailing a wake of flattened grass sweeping across the field towards them. They did notice when the car stopped by their bicycles. The driver got out and opened a rear door. A big man in a dark suit emerged from the rear and stood by the door.

"Jerry?" the big man called. "Gerald William Williams?" He spoke in exaggeratedly polite tones. Jerry climbed down from his tree. "Yes?" he asked.

"Your father has been hurt," the big man said. "He wants you to come right away." George had tied his guy rope and hurried down from his tree. He was standing by Jerry's side. "Excuse me," George said, "but who are you?"

"Come on, kid. We don't have all day." The hissing voice came from another man inside the car.

"George!" Jerry shouted. "It's my father. He's been hurt. Don't stand around asking questions. Let's go." He was already scrambling into the back seat of the huge automobile.

"You don't know these men," George started to say; then he felt himself held firmly and pushed toward the car. He began to resist, but then he saw that inside the car the small man held a pistol aimed roughly at Jerry's right eye. George let himself be shoved into the car. The big man threw himself into the seat next to George and slammed the massive door. The small man sat on a jump seat facing Jerry. The car started to move.

The windows had heavy curtains across them. A thick sheet of glass separated the rear seat area from the front. The small man reached out and flicked another curtain closed behind the driver.

"Like a snake striking," George thought. The small man was thin and dressed in a tight plaid suit that reminded George of snakeskin. The rear seat area was now a dark, closed compartment. The boys could not see out.

George considered diving for the door to get away. He looked at the door, then looked again. He looked at the other door. The big man saw his glance and smiled. The door handles and window handles had been removed. The doors could not be opened from the inside.

The men took off their neckties, then George and Jerry felt their arms pulled behind their backs and their wrists tied with the neckties. The big man lit a cigar, then spoke.

"You might as well relax," he said, puffing on his cigar and settling back into his seat. "We're going a long way. You're going so far from anywhere there won't be any point in trying to escape. Har-har," he laughed and puffed on his cigar. "Karaff-hack," he coughed, sputtering smoke.

They drove and drove. The ride was so smooth the boys could not tell if they were going slow or fast. The minutes flowed into an hour or two. George wanted to see outside.

Making believe the long ride had made him sleepy, he slumped over, leaning against the bear of a man, who obligingly moved over. Soon George was almost lying down on the wide seat. He had enough room. He lashed out his leg and pushed the curtain open with his foot. Quickly

he sat up and looked out.

He saw open fields, fence wire, and a telephone pole slipping backward. He saw these briefly, as if he were inside a large camera and the shutter has clicked open and shut once. A big hand threw the curtain shut.

"Don't try anything like that again," the big man growled. "You'll be sorry. I mean it."

George believed him. He was already sorry he had not learned more from his glimpse outside.

Finally the car's smooth motion stopped. The door swung open. The bright sun dazzled the boys' eyes.

The three men had a brief conversation next to the car. "The little one is more trouble than he's worth," the slender man hissed. "Williams is the one we want. Why don't I just blow the other one away?"

The driver took time to consider this suggestion. He looked into the car at George, then said, "No. Keep them both as long as they don't make any trouble. His old man may be worth something, too."

George felt they were just acting out this little skit to scare him into a cooperative mood. But, of course, he was not sure.

"Put them in the barn," the snake hissed to the bear.

Locked inside the barn, the boys struggled back to back and finally succeeded in untying each other's hands. Then Jerry sat down on a bale of hay and hit it with his fist. The bale was firmer than he had expected. He rubbed his hand and looked around to see what George was doing.

George walked around the barn, looking at everything in the dim light which sifted through the pigeonholes high up in all the walls. There was a hay door high above the loft. Slowly, George climbed an old ladder, testing each rung gingerly with more and more weight before finally trusting his balance to it. He reached the high door. "It's nailed shut," he called down just loud enough for Jerry to hear but not loud enough to be heard outside. "There are about a hundred ten-penny nails driven through to a couple of two-by-twelves I can see through the cracks. We'd never get through that."

Jerry's head sank lower and lower in his hands. George kept on searching. The pigeonholes and the locked main door were the only ways out. Jerry, feeling the minutes drag by, hit the hay bale again and again. George came back and reported on his explorations.

"No way out," he said, "but I found an old door buzzer installed in the back by the dairy stalls. The wires run all the way up to the rafters and then out the main door, but they're not connected to anything any more. The ends just dangle by the door."

"Wonderful," Jerry said sadly.

"But that's not all," George said with a smile. "I also found these." He held up an almost-empty paper towel roll and an almost-empty aluminum foil dispenser, left over, perhaps, from some picnic which had been forced by rain into the barn. "And I found a damp book of matches and put them in the sunshine by the crack of the door to dry."

"Wonderful," Jerry repeated. "I may cry."

"And there's some interesting junk in that barrel over there," George went on, pointing.

Jerry looked up through darker and darker eyes. He did not lift his chin from his hand. He did not answer.

"But best of all," George concluded happily, "this!" He stepped back and carefully picked up, from an old stone sink, one more prize: a rusty old razor blade.

Jerry looked from the razor blade in George's hand to George's eyes. Jerry's expression was so woebegone that George had to smile. "Here we've been kidnapped," Jerry began slowly, "we're locked in this barn without a hope of getting out, and even if we got out, we'd be a hundred miles from anywhere . . ."

"If you believe them," George interrupted, with a jerk of his thumb down toward the house.

"If you believe them," Jerry agreed. "But right now I do believe them. We're stuck out here without a hope, and our parents are probably worried sick right now because some strange hood is calling them demanding ransom for us, and you're gathering junk. If you're wondering why your enthusiasm depresses me, it's because I don't believe you're playing with a full deck."

"Wait," George said. "This may not be just ordinary junk. This may be . . . well, I have heard you can use these old blue steel razor blades for a detector in a crystal set instead of a crystal. It requires delicate adjustment of the cat's whisker, but they say it can be done, and I believe it. After all, any imperfect connection may rectify rf. That's why some people can hear local broadcast stations in their rain gutters or in their bedsprings."

"So?" Jerry asked.

"So," George said, pointing proudly to his little collection, "this junk might turn out to be radio junk."

Jerry groaned. "George, you have lost your mind," he stated judiciously. "Ham radio is all you can think about." He sagged forward and cradled his chin in his palms.

"Easy, buddy," George said. "This radio junk might give us an idea of where we are."

"You have a plan?" Jerry asked. He tried to sound sarcastic, but he couldn't help letting a little optimism creep into his voice.

"Yes, a plan—sort of," George went on. "If we know where we are, we might know what direction to go in if we get a chance. And besides, we don't have anything else to do right now."

"So what do we do?" Jerry no longer looked depressed.

"Well, we see if we can make a DF set, and . . ."

"DF?" Jerry asked.

"Direction-finding," George answered. "A direction-finding set is a radio receiver with a directional antenna. If we can hear stations in known locations, we might be able to locate ourselves in reference to them. We can try to make a crystal set out of the stuff we have; then we might be able to use it as a DF set by making a loop antenna out of the wire from the buzzer."

"Wow," Jerry said. Then he shook his head and hit the hay bale again. "And we do all this," he said, "with a piece of aluminum foil, a few paper towels, and an old razor blade?"

"Yes," said George. "And the bell wire from the door buzzer, this old jar lid, and a few more parts. We'll build it on the counter of this sink."

"Oh, no," Jerry groaned. "I remember what we needed when we made the crystal set at home: a variable capacitor and a coil, earphones, not to mention a crystal and holder, and an antenna and a ground system."

"You're right," George said. "But if we can use this razor blade as a detector, making the earphone will probably be the trickiest part. The rest shouldn't be too difficult. We'll make

the coil variable instead of the capacitor. We can use the wire that runs through the rafters to the old buzzer for our antenna, and this cold water pipe will be our ground."

"Okay," Jerry agreed. "We might as well try it."

"Good. Do you have any tools with you? I left all mine back with our bikes."

"I just have my pocketknife," Jerry said.

"Good. That should let us get to work."

"What should I do?"

"Well, to start the earphone, we'll need to find a couple of nails. And we'll need something to hold the razor blade steady."

"Good. What size nails?"

"Two-penny finishing would probably be good," George said. "I'm just guessing. We'll be happy with anything you can find that isn't too big or too rusty."

"Great," Jerry said happily, because he didn't know a two-penny finishing from a two-bit starting, whatever that might be. While Jerry searched, George stripped bell wire off the door buzzer magnets and wound it around the cardboard tube from the aluminum foil package. Using the pocketknife, he made slits in the tube to hold the wire. Then he stripped insulation from a path down the coil where the slider would contact the windings.

"How do we know how long to make the coil?" Jerry asked.

"We don't. We'll just have to make it as long as we can, and we'll make as much capacitor as we have foil and towel. Then we'll just hope for the best," George confided.

"Oh, I see," Jerry said. He was beginning to sound discouraged again. "Here's a couple of shiny nails," he went on. "And I found this." It was an old coffee can with a plastic cap.

"What's inside it?"

"It seems to be white flour, and the cap seems to have kept it fresh and dry. Should we throw out the flour and keep the can in case it might come in handy?"

"You seem to be getting into the spirit of scrounging," George said. "Yeah, you can if you want, but I don't really think we'll have any use for it."

Jerry began to tip the can to pour the flour into the barrel, then he stopped. "We can use this," he said smiling, almost beaming for the first time since he had clambered into the limousine. "I'll tell you about it later. What's next for the radio?" He soon found a large antique, and now rusty, C-clamp to hold the razor blade, then asked, "What next?"

"Let's see. You make the capacitor," George said. "Tear the aluminum foil in two and make a double sandwich with three paper towels. Put the sandwich flat on the sink counter and weigh it down with that big board over there. Scrape some insulation from the ends of some lengths of bell wire and make a lead from each plate. Scrape back six inches or more and we'll hope the pressure of the sandwich is enough to make contact. I'll try to make an earphone by pounding these nails a little way into a piece of wood and winding lots of bell wire around them. Later, we'll place the jar lid over the nails and hope there's enough energy in the coils to make the lid vibrate sound waves we can hear."

While they worked, Jerry said, "Did you know flour can be explosive? If it's dispersed in air, there's so much surface area that it can explode. My science teacher demonstrated that last year. He put some flour in the end of a rubber tube and a lighted candle under an inverted coffee can. Then he blew into the other end of the tube, blowing the flour around in the can. There was a loud boom, and the can flew in the air."

"Huh," George answered.

"And there's a stub of a candle in the trash can and a garden hose in the loft."

"Hmm," George said. They made their plans.

Later, the boys were ready to test what was perhaps the largest, roughest-looking crystal-less crystal set in the world. The homemade capacitor lay under its board. Wires ran from it to either end of the coil on the cardboard tube. Antenna wire dropped from the rafters and connected to one end of the tuner, the other end of which was connected to the cold water pipe. From the antenna end, another wire ran to the antique C-clamp Jerry had found, which held the razor blade upright. All electrical connections consisted of about a foot of scraped bell wire wound around and around the desired point. The cat's whisker touching the blade was a piece of bell wire anchored under a rock for stability. From there a wire disappeared under the jar lid, the diaphragm of the earphone. Another wire crept from under the lid to the cold water pipe.

"Well," George said. "That's our amazing crystal set."

"The amazing thing will be if it works," Jerry responded. He leaned over so his ear was over the jar lid. George moved the slider up and down the coil and looked questioningly at Jerry.

"Nothing," Jerry said.

George moved the cat's whisker to another part of the blade, then moved the slider again.

"Nothing," Jerry repeated. "Oh, why did we waste time with this thing anyway? Just look at it," he said in disgust. He reached out and, before George could stop him, slammed his fist down on the capacitor sandwich. Both boys heard a tiny tinny clink in the earphone.

Jerry bent over the earphone again and moved the slider along the coil. "There's something here," he said, "but I can't hear it well enough to understand."

"I was afraid of that," George said. He began to pace; the orbit of his pacing widened. Then his eye fell on an old oatmeal box in the trash barrel. "Hold this over the lid," he told Jerry.

Jerry then lowered his ear to the open mouth of the box. "That's it," he said happily, careful to keep his voice low. "It's a radio. It works. There's music."

"Great. Let me listen," George said. "Super!" he announced in his most judicious tones. "It's stronger than I dared to hope—which means you can just about hear it." While holding the oatmeal box earphone, he moved the slider. "There's another station," he said. He moved the slider up and down the coil slowly. "That's it," he said, "two stations, both fairly strong.

The boys shook hands triumphantly. Then Jerry leaned back over the oatmeal box. He listened in silence a while, then said, "Here, this is it. They're going to identify." He leaned close to the mouth of the box and held his breath so as not to miss the announcement. "Hey, it's KTOK!" he reported.

"KTOK?" George echoed. "That's Oklahoma City. That's home!"

Jerry started to shout, but then caught himself so quickly it would have sounded like little more

than a sneeze to anyone outside. He tuned down to the other station and listened. He started humming with the music. "Wait," he said. "It's over now. The DJ's talking. Wait. It's . . . yes. This is KNOR."

"KNOR — Norman!" George said. "That's a good sign. We can't be far from home. KNOR is at 1240, and KTOK is about one megahertz. I guess our radio only tunes the high end of the broadcast band. Let's make our DF loop."

They pulled all the stiff wire down from the rafters and wound it in a big loop, tying the loop to a board they could use for a handle. "Now let's see if we can hear anything at all," George said. He stood with the loop in front of him. "Do you hear anything now?"

Jerry, bent over the earphone, answered, "Nothing. Nothing at all."

George turned slowly, holding the loop in front of him. "Nothing, nothing," Jerry said.

"Tune it again," George suggested. "The different antenna could make a difference in the tuning."

Jerry moved the slider all the way down the coil,then slowly all the way back up. He tried the whole range of the coil again. "Nothing," he said. The boys looked at each other for a long minute while neither thought of anything to try or say. Then Jerry, perking up somewhat, said he would try one more time. He held his breath, and slowly slid the slider down the coil. "Nothing," he said. "No. Wait! There is . . . something . . . here, you'd better listen to this."

Jerry took the antenna from George, who put his ear to the oatmeal box. He heard a rhythmic hissing. He realized why Jerry had wanted him to listen. When his ear adjusted to the strange hiss, he could copy CW strong and clear: "OLZ OLZ OLZ DE W5RB QNI K."

"Well, I'll be," he said. "We can tune the 80 meter band. That's Gil calling the Oklahoma Traffic Net."

Jerry took a step toward George. The signal George was again copying became weaker. "No," George said. "Turn the other way. That's it. More. More. No, now it's getting weaker again. That's right, back this way a little. Right. Right there, I guess. He's due west of us."

"Wow," Jerry said. "Do you know this guy Gil?"

"I've contacted him on the net. I know he has a farm somewhere south of the city. His signal is really strong. We can't be very far from him."

"Okay," Jerry said, his voice quavering with eagerness and apprehension. "Let's get on with the plan. Step two."

"HEY! SNAKE! BEAR! DRIVER! COME QUICK! HEY, YOU THUGS, ON THE DOUBLE!" The boys yelled at the tops of their lungs, then they subsided and hid behind a wall of hay bales.

Soon they heard the crossbar moving on the main door, then the door opened a little — just a little. Nothing else happened. The boys watched the door. Jerry held one end of a water hose. The hose lay across the floor under the hay and ran under a dividing wall and into the stalls at the rear of the barn.

Into the strip of light at the door, first Snake's head appeared, then, over his, Bear's. They looked around, did not see the boys, and then looked at each other. George nudged Jerry to indicate "Now." Jerry blew into the hose.

BOOM!

From the back of the barn, a small explosion roared. The men at the door looked at each other, then ran past the boys, around the partition. George and Jerry burst from behind the hay and sprinted for the door. Outside, they pushed the door shut and locked it with the four-by-four crossbar.

"The driver," Jerry said. "Should we do step three?"

George hesitated a moment before answering. "Guess we'd better," he said. They ran to the limousine and opened both rear doors and the driver's window. George reached in and started blowing the horn while Jerry hid behind the car. He blew it again and again. The driver came out of the house and saw George.

"Hey, what are you doing out here?" the driver shouted and started to sprint to George. As he ran, he looked up at the barn and back at George, who turned deliberately and sat in the rear seat of the car. The driver reached the car and dived in after George. In another moment he would have grabbed George, but Jerry came out from behind the car and hurried around behind the man.

"Hey, you!" Jerry shouted. The driver hesitated for just the necessary moment. George got away.

The driver looked back at Jerry. "Hi there," Jerry said and slammed the door. The driver's face seemed to show in this moment that he understood what was happening but knew he couldn't react quickly enough to stop it from happening. George slammed the other door. The driver was trapped in the rear of the car with no inside door handles.

The boys started running west up a long slope as hard as they could go. Behind them they heard pistol shots from the barn. "They may be able to shoot their way out," George said. "Let's give it all we've got." Jerry, not wasting his energy talking, was passing George.

Cresting the hill, looking into a valley under the setting sun, the boys saw a tall tower with a large beam antenna on top. The house below the tower was strung with various wire antennas. The two boys ran about 200 yards from the crest of the hill to the door of the house. They knocked on the door, then banged on it.

The door opened. A thin man with grey hair and friendly eyes stood in the doorway.

"You're Gil W5RB, right?" George gasped, between gulping air. "I'm George WD5XZF. We were kidnapped and we escaped. Please let us in."

Gil stepped out of the way. Breathless, the boys ran in, and, while Gil closed and locked the door, relaxed for a moment in the luxuriance of repeated deep breaths.

"It's good to meet you," Gil said, and shook George's hand. George introduced Jerry while Gil picked up the telephone, and Jerry also felt the firm handshake.

"Uh-oh," Gil said, looking at the telephone receiver in his hand. He jiggled the cradle up and down, listened again, then lowered the receiver to its cradle.

"The phone just went dead, boys," he said, his face serious. "That means your friends are out there."

"And they have guns," Jerry said.

"Pistols," George said.

"So I guess we're just sitting ducks," Jerry said sadly. "They can push their way in here and . . . "

"I doubt if they'll rush us right away," Gil said. "They probably expect a farmer to be armed. They'll feel the situation out for a while. And we have another card to play." He turned toward the rear of the house.

The boys followed into a

back room full of radio equipment: cabinets and racks of meters, dials, knobs, and switches. "Uh-oh," Jerry said. "Your clock has stopped."

"They found the main power switch in the barn," Gil said. "But I wasn't going to use the big rig anyway." He picked up a small handie-talkie, pressed the button, and talked into the grill.

"K5VJO, this is W5RB."

After a minute's pause, the answer came loud from the grill on the little instrument. "W5RB from K5VJO. It took me a while to get back to the jeep, Gil. What's up?"

"Jeep?" Jerry asked.

"Jeep," Gil affirmed with a smile, then pushed the mike button. "Al, this is a Mayday. Repeat, Mayday. Two young men were kidnapped this morning and taken to the abandoned farm next to me. They escaped to my house. The kidnappers are outside right now, armed with pistols."

"Okay, Gil," the voice from the radio said. "We'll take care of it. Hang loose, now."

"Thanks, Al," Gil said. He turned to the boys. "I heard Al on the air earlier today. He's on weekend drill with the National Guard around Edmond."

"I'd feel a lot better if . . ." Jerry began.

"Let's try not to worry," Gil said. "I think we've done all we can for now. Would you boys like something to eat?" He carried his handie-talkie into the kitchen, and of course the boys followed.

"You talked to Edmond with that little thing?" Jerry asked.

"That's right," Gil said. "Our club has a repeater up on the channel 9 tower. We're just one of hundreds of repeater clubs around the country. The repeater picks up our handie-talkie and automobile-mobile transmissions and retransmits them from its high, central location, covering the whole metropolitan area. I heard Al say he was going to monitor the repeater during his Guard drill. He's Emergency Coordinator with the Air Cavalry unit."

Gil put a big frying pan on the stove and took some hamburger patties from the refrigerator. Soon the patties were sizzling in the pan and the boys were spreading catsup, mayonnaise, and mustard carefully to the edges of their sliced hamburger buns. They were pouring three glasses of milk when the house began to shake in a violent flapping thunder. They ran to the window, cautiously parted the drapes, and looked outside. Five giant army-green helicopters circled and swooped toward the house from five different directions. As the boys watched, the kidnappers ran out of the barn toward the limousine. One chopper landed in a terrible cloud of dust next to the car. Four Guardsmen, dressed in fatigue uniforms and combat boots and armed with M-14 rifles, jumped to the ground and faced the kidnappers, who stopped, looked astounded, shook their heads in disbelief, and then threw their pistols to the ground and raised their hands.

The ground fell away dizzyingly. The boys felt their insides pressing down. The earth below tipped and rotated. It was their first ride in a chopper. In all the excitement they had forgotten their hamburgers. They were eager to get back to their hillside, back to their bicycles, and then to get home to supper. ■

Tips for VOM Users

— current topics

Put some meaning into your measurements.

Most amateurs, when they learn about test instruments, particularly multimeters, understand that such instruments must not be used in such a manner that they "load" the circuit being tested. Otherwise, readings will be obtained which do not truly indicate the parameter one is trying to measure. In the case of multimeters when measuring voltage, the Ohms/volt rating of the multimeter can be used to determine the loading effect the multimeter will have on a circuit when the meter is used on any given voltage range.

However, a point that is often neglected when using multimeters is to evaluate what effect the meter is having on a circuit when measuring current. This point was not stressed when many old-timers learned radio, but today, with the widespread use of low-voltage, high-current circuits, due to the use of solid-state devices, it can take on considerable significance.

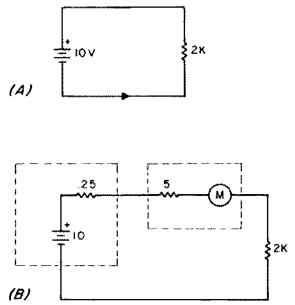

Fig. 1.(a) Simple resistor circuit and (b) representation of other circuit resistances that should be considered when measuring current flow.

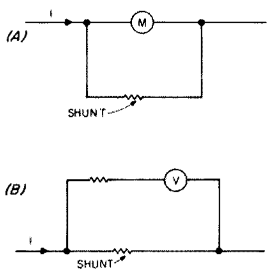

Fig. 2. Two methods of using shunt resistors for measuring current.

There are two points to watch in making current measurements. One is the relationship of the resistance of the meter being used to measure current in comparison to the other resistances in a given circuit as far as it affects the current reading. For instance, in Fig. 1, we have a circuit represented by the 2,000-Ohm resistance powered by a 10-volt battery, and want to measure the current flow.

If we insert a milliampere meter in the circuit, as shown in Fig. 1(b), two other resistances actually have to be taken into account. One is the internal resistance of the battery, and the other is the internal resistance of the meter. These are represented by the 0.25-Ohm and 5-Ohm resistors, respectively. If we had just the elements of Fig. 1(a), a 5.0-milliampere current would flow. With the added resistances of Fig. 1(b), one can easily enough calculate, using Ohm's Law, that 4.99 milliamperes flows in the circuit.

Since this certainly checks out closely enough, let's consider the other point to be careful of in making current measurements—how the the relationship of the resistance of the meter being used to measure current flow in comparison to the other resistances in the circuit changes the operating voltage across the circuit. Remember that the circuit was represented by a 2,000-Ohm resistor. In reality, of course, many cir-

cuits are not linear in their loading characteristics across a supply voltage. That is, the apparent resistance will change according to the supply voltage used. So, if a meaningful current measurement is to be made, the process of taking it must not significantly change the voltage across a circuit. For the case of Fig. 1(b), it does not take too much exercise of Ohm's Law to calculate that the actual voltage across the 2,000-Ohm resistor is practically unaffected at 9.97 volts.

One may ask why the foregoing should be worried about when taking current measurements if the meter's effect on the circuit is so insignificant. The example cited does represent realistic values. That is, 5 Ohms resistance for a 5- or 10-milliampere instrument would represent the coil resistance of a good quality d'Arsonval-type meter movement. However, in reality, one usually doesn't use a basic milliampere meter, but, rather, the current ranges on a multimeter. The usage of the latter brings about a new set of conditions.

Classic ammeter circuits are usually formed by using a basic meter movement and then placing shunts across it as shown in Fig. 2(a). However, in most of the imported multimeters which abound in ham shacks, the meter in the multimeter is actually used as a voltmeter when current measurements are being made, as shown in Fig. 2(b). The meter has a resistance in series, and then the voltage is measured across a current shunt. The reason for doing this is that many multimeters use quite sensitive meter movements (as low as 10 microampere movements) in order to achieve good sensitivity on voltage measurements, or, said in another way, to achieve a high Ohms/volt characteristic so loading effects when taking voltage measurements are minimized. To use these meters directly in the current measuring scheme of Fig. 2(a) would require extremely close tolerance and, hence, expensive shunts. This is particularly true for the higher current ranges, since the percentage of the total current that can flow through the meter becomes very small.

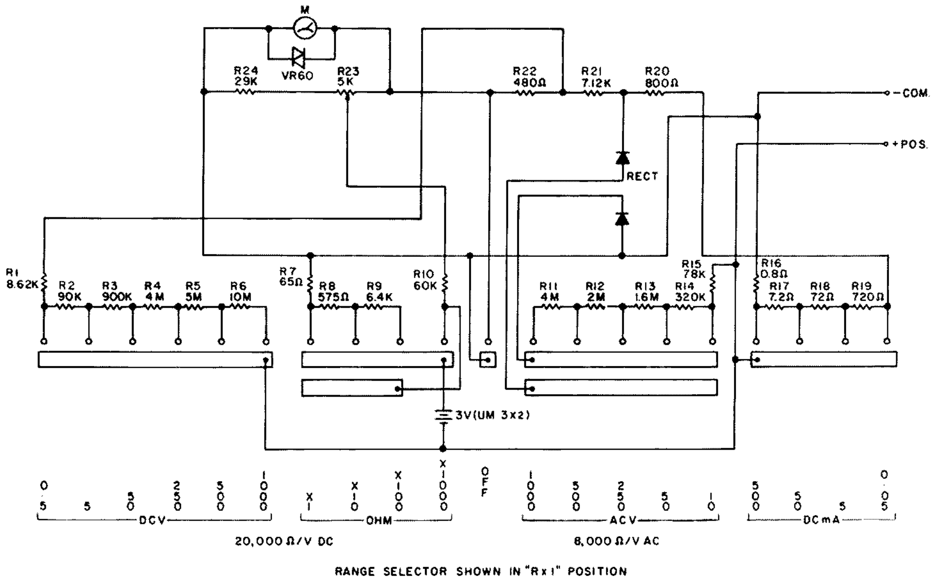

Fig. 3. Typical schematic of moderately-priced ($15-35) multimeter. Note the arrangement of the resistors for the current ranges on the right side.

Fig. 3 shows the diagram of a typical medium-quality multimeter. Note that, for the current ranges, the meter is set up to measure the voltage across current-shunt resistors of approximately 80, 8, or 1 Ohm. The voltage drops that were measured across the terminals of the multimeter when it was used for different current measurements are shown in Table 1.

If one looks at the voltage drops across the meter terminals for full-scale deflection on any of the milliampere ranges, the message should be getting clearer. Up to ½ volt lost across the meter terminals can be very significant when trying to measure the current drawn by some low-voltage battery-operated circuit or some high-current IC circuit. The ½ volt represents 17% of the supply voltage for a 3-volt circuit and 11% for a 4.5-volt circuit. But one cannot relate these percentages directly to the error in the current being measured. As was mentioned before, circuit loading is often not linear. So a small increase in the actual voltage across a circuit may increase the current drawn from a supply by a significant amount. Therefore, the real error in current measurement might be several times greater than the basic percentage error might indicate. This can have significant effects when trying to troubleshoot equipment, evaluate what sort of batteries to use for a circuit, check the power dissipation of a low-voltage circuit, etc.

The foregoing tabulation also indicates how one can overcome the situation. Namely, by measuring current on a range which produces minimum meter deflection so as to reduce the voltage drop in the multimeter. Of course, one sacrifices accuracy of measurement in this manner, but that is the compromise required with moderately-priced multimeters. It would be a good idea to check the actual voltage drops on the current ranges on a multimeter using another instrument and affix a small label to the multimeter giving the values. Who knows? Maybe someday even the manufacturers will do this along with the Ohms/volt figures they seem more eager to advertise. ■

Range	Current	V. Drop	Current	V. Drop
50 A	10 A	.025	50 A	.075
5 mA	1 mA	.075	5 mA	.4
50 mA	10 mA	.08	50 mA	.4
500 mA	100 mA	.16	500 mA	.5

Table 1.

Social Events

CIRCLEVILLE OH
MAR 4

The King of the Pumpkin Ham Fiesta, sponsored by the Teays Amateur Radio Club, will be held from 9:00 am to 5:00 pm on Sunday, March 4, 1979, at the fairgrounds coliseum, Circleville, Ohio. There will be an indoor flea market, new and used equipment, door prizes, refreshments, and free parking. Table spaces are available at $3.00 each. Advance admission is $1.00; $2.00 at the door. For advanced reservations and information, contact Dan Grant W8UCF, 22150 Smith Hulse Road, Circleville OH 43113; (614)-474-6305.

STERLING IL
MAR 4

Sterling Rock Falls Amateur Radio Society will hold its annual hamfest on March 4, 1979, at the Sterling High School Fieldhouse, 1608 4th Avenue, Sterling, Illinois. Tickets are $1.50 in advance; $2.00 at the door. A large indoor flea market is restricted to radio and electronic items only. There is plenty of free parking available, including an area to accommodate campers and mobile trailers. There will be no advance sale of tables. We will take reservations for commercial enterprises only. There will be bargains, miscellaneous prizes, and food. Talk-in on 146.94. For tickets, write Don VanSant WA9PBS, 1104 5th Avenue, Rock Falls IL 61071. Make checks payable to Sterling Rock Falls Amateur Radio Society. Please include an SASE.

DEMAREST NJ
MAR 10

The Chestnut Ridge Radio Club will hold its flea market on March 10, 1979, at the Demarest Methodist Church, 109 Hardenburg Road, Demarest, New Jersey. Tables are $5.00, and tailgating is $3.00. There is no admission fee for buyers. There will be hot dogs, soda, and door prizes. For more information, contact Jack Meagher W2EHD at (201)-768-8360, or Andy Woerner K2ETN at (201)-261-1047.

FLEMINGTON NJ
MAR 17

The Cherryville Repeater Association will hold its annual hamfest on March 17, 1979, from 10:00 am to 5:00 pm, at the Field House of Hunterdon Central High School, just north of Flemington, New Jersey, on Route 31. Admission is $2.50 per person. There is plenty of space, with over 200 sellers' tables, and displays from major manufacturers. There will be seminars and door prizes.

VERO BEACH FL
MAR 17-18

The Treasure Coast Hamfest will be held on March 17-18, 1979, at the Vero Beach Community Center, Vero Beach, Florida. Activities will include prizes, drawings, and a QCWA luncheon. Admission is $3.00 per family. Talk-in on 146.13/.73, 146.52/.52, and 222.34/223.94. For information, write PO Box 3088, Vero Beach FL 32960.

MIDLAND TX
MAR 18

The Midland Amateur Radio Club is having its annual swapfest on Sunday, March 18, 1979, at the Midland County Exhibit Building, Midland, Texas. There will be door prizes. Preregistration is $4.50; $5.00 at the door. Talk-in on 146.16/146.76. For information, write Midland Amateur Radio Club, Box 4401, Midland TX 79701.

JEFFERSON WI
MAR 18

The Tri County ARC Hamfest will be held on March 18, 1979, at the Jefferson County Fair Grounds, Jefferson, Wisconsin. Advance tickets are $1.50. Reserved 6-foot tables are $2.00 in advance, while 6-foot space is $1.00. For information, send an SASE to Glenn Eisenbrandt WA9VYL, 711 East Street, Fort Atkinson WI 53538.

LAWTON OK
MAR 23-25

The Lawton-Fort Sill Amateur Radio Club, Inc., will hold its 33rd annual hamfest at the Montego Bay Motel Complex at Lawton, Oklahoma, the weekend of March 23-25, 1979. There will be the usual large flea market, ARRL officials, technical programs, QCWA breakfast, and activities for the ladies.

EAST RUTHERFORD NJ
MAR 24

The Knight Raiders VHF Club, Inc., will hold its world-famous flea market at St. Joseph's Church, East Rutherford, New Jersey, on Saturday, March 24, 1979. Doors open at 10:00 am. There will be free admission and free parking. Refreshments will be available. Flea market tables are available for: $5.00/full table or $3.00/half table, in advance; $6.00/full table or $3.50/half table, at the door. Talk-in on 146.52 and 144.65/145.25. For further information, call Bob Kovaleski at (201)-473-7113 or Jack Mandelberger at (201)-857-0016 (evenings only). Send reservations to: R. Wetzel, 419 Union Ave., Rutherford NJ 07070, and make checks payable to: Knight Raiders VHF Club, Inc.

FT. WALTON BEACH FL
MAR 24-25

The Playground Amateur Radio Club will hold its ninth annual North Florida Swapfest on Saturday and Sunday, March 24-25, 1979, at the Ft. Walton Beach City Fairgrounds, Ft. Walton Beach, Florida. Advance registration is $1.00; $1.50 at the door. Swap tables and meetings are all under cover. There will be QCWA, MARS, and ARES seminars. Talk-in on 52 and 19/79. For more information, write PARC, Box 873, Ft. Walton Beach FL 32548.

WAUKEGAN IL
MAR 25

The Libertyville and Mundelein Amateur Radio Society will hold its second annual Lamarsfest on Sunday, March 25, 1979, at the J. M. Club, 708 Greenwood Ave., Waukegan, Illinois. Doors will open at 7:00 am.

There will be plenty of free parking, door prizes, and a large indoor flea market for radio and electronic items. Tables will be available at $4.00 each. Advance tickets are $1.50; $2.00 at the gate, with children under 10 free. Hot lunch will be available and there will be plenty of commercial exhibits and demonstrations. Talk-in on 146.94. For further information, write LAMARS (include SASE, please) at 1226 Deer Trail Lane, Libertyville IL 60048, or call (312)-367-1599.

MAUMEE OH
MAR 25

The Toledo Mobile Radio Association will hold its 24th annual auction and hamfest on March 25, 1979, at the Lucas County Recreation Center, Maumee, Ohio. Tickets are $2.00 in advance, $2.50 at the door. Parking is free. Prizes include a Kenwood TS-520, a Yaesu CPU-2500R/K, a Wilson Mark IV, and a Bearcat 210 Scanner. Talk-in on 146.52/.52 and area repeaters on 146.01/.61, .19/.79, .34/.94, .87/.27, and .975/.375.

MUSKEGON MI
MAR 30-31

The Muskegon Area Amateur Radio Council is sponsoring the ARRL Great Lakes Division Convention and Hamfest at the Muskegon Community College in Muskegon, Michigan, on March 30-31, 1979. This event will feature manufacturers' exhibits, technical forums, and a large swap shop. Ample parking and dining facilities are available. Friday evening at the Muskegon Ramada Inn, there will be a "Ham Hospitality" with libation courtesy of the MAARC and a Wouf Hong initiation. For additional information, contact MAARC, PO Box 691, Muskegon MI 49443, or H. Riekels WA8GVK, (616)-722-1378/9.

ST. LOUIS MO
MAR 31

Mayor Conway of St. Louis has proclaimed March 31st as Amateur Radio Day, and, in conjunction with this, the Gateway Amateur Radio Association is sponsoring a hamfest which promises to be a good one. Hamfest hours are 8:00 am to 6:00 pm at the H. J. Cervantes Convention Center. Scheduled events include: Wayne Green on microcomputers, an antenna forum by Hy-Gain, an FM and repeater forum by Motorola and VHF Engineering, FCC Q & A, a station-design forum by Drake, a low-cost transceiving forum by Atlas, a linear amplifier forum by ETO, a DX forum featuring the Navassa group and N9MM, a revolutionary method of learning Morse code, and an

✓ Reader Service—see page 211

OSCAR forum. There will be special meetings for teenage hams, Ten-Ten members, Breakfast Clubbers, SWOT members, YLRL members, and others. Activities for YLs include a fashion show, a cosmetic display, and a tour of St. Louis. Talk-in on .34/.94, .37/.97, and .52. Admission is $3.00. For further information, please contact Bob Heil K9EID, PO Box 68, Marissa IL 62257, or phone (618)-295-3000.

WORCESTER MA
MAR 31

The WPI Wireless Association will sponsor its first annual Spring Flea Market on Saturday, March 31, 1979, from 9:00 am to 4:00 pm, at the WPI campus in Worcester, Massachusetts. For more information, write WPI Wireless Association, Box 2393, Worcester Polytechnic Institute, Worcester MA 01609.

COLUMBUS GA
MAR 31-APR 1

The Columbus Amateur Radio Club will hold its first annual hamfest from March 31-April 1, 1979, at the Columbus Municipal Auditorium, US 27 & 280, Columbus, Georgia. Donation is $1.00 at the door. There will be plenty of free parking and overnight free RV space. Exhibitors and flea market will be inside, with a free flea market outside. Talk-in on 28/88. For advance registration and details, write Bob Glasgow N4BGN, 1503 Layard Drive, Columbus GA 31907; (404)-561-7746.

NATCHEZ MS
APR 1

The Old Natchez ARC Hamfest will be held on Sun-

day, April 1, 1979, at the Natchez Convention Center, Natchez, Mississippi. The event will be indoors and air-conditioned. There will be free admission and swap tables. Talk-in on 146.31/.91 and 146.52. For information, write ONARC, 1226 Magnolia Avenue, Natchez MS 39120.

PAINESVILLE OH
APR 1

The Lake County A. R. A. will hold its 1st annual Lake County Hamfest on April 1, 1979, from 8:00 am to 4:00 pm, at the Lake County Armory, located next to the N. E. corner of the Painesville Fairgrounds, Rt. 20, Painesville, Ohio. There will be indoor space for exhibitors, a flea market, and an auction. Reserved tables are $2.00 for a full table and $1.00 for a half table. Admission is $2.00 with children under 12 free. Talk-in on 52/52 and 147.81/147.21. For information, write L'CARA, PO Box 868, Painesville OH 44077, or call (216)-257-4486.

PHILADELPHIA PA
APR 1

The Penn Wireless Association will hold its Tradefest '79 from 8:00 am to 4:00 pm at the National Guard Armory, Southampton Road at Roosevelt Blvd. (Rt. 1), ½ mile south of turnpike exit 28. General admission is $2.00. Setup is at 7:00 am. Sellers may rent a 6' x 8' space for $3.00; you must bring your own table. Some tables are available for $1.00, and a minimum number of power connections are available for $2.00. There will be refreshments, displays, and a rest area. Talk-in on 146.37/.97 and 146.52. For more information, contact Chuck Miller AD3X, (215)-943-3973.

TOWSON MD
APR 1

The Greater Baltimore Hamboree will be held on Sunday, April 1, 1979, beginning at 8:00 am, at Calvert Hall College, Goucher Blvd. and LaSalle Road, Towson, Maryland. The college is located south of Exit 28, Beltway (Interstate 695). There will be food, prizes, and a giant flea market. Admission is $3.00. There will be tables available inside the gym and the cafeteria. For information and table reservations, contact Bro. Gerald Malseed W3WVC at Calvert Hall College, 8102 La Salle Road, Towson MD 21204, or call (301)-825-4266.

ROCHESTER MN
APR 7

The Rochester Amateur Radio Club and the Rochester Repeater Society will hold their Rochester Area Hamfest on Saturday, April 7, 1979, at St. John's School Gymnasium, 490 W. Center St., Rochester, Minnesota. Doors will open at 8:30 am. There will be a large indoor flea market for radio and electronic items, prize raffles, refreshments, and plenty of free parking. Talk-in on 146.22/.82. For further information, contact RARC, c/o KØTS, 2514 N.W. 4th Ave., Rochester MN 55901.

MADISON WI
APR 8

The Madison Area Repeater Association, Inc., will hold its seventh annual Madison Swapfest on Sunday, April 8, 1979, at the Dane County Exposition Center Forum Building in Madison, Wisconsin. Doors will open at 7:00 am for sellers and exhibitors and at 8:00 am for the public. The Forum Building has over 20,000 feet of space for exhibitors and the flea market. There will be plenty of space for parking, with overnight camping available. Hotel accommodations are also available within walking distance of the Swapfest. There will be door prizes, an all-you-can-eat pancake breakfast, and a Bar-B-Q lunch, as well as free movies throughout the day. Admission is $1.50 in advance and $2.00 at the door. Tables are $3.00 in advance and $3.50 at the door. Children twelve and under are admitted free. Talk-in on WR9ABT, 146.16/.76. For reservations or information, write M.A.R.A., PO Box 3404, Madison WI 53704.

KANSAS CITY MO
APR 21-22

The P.H.D. Amateur Radio Association, Inc., of Liberty, Missouri, will sponsor the tenth annual Northwest Missouri Hamfest on Saturday and Sunday, April 21-22, 1979, from 11:00 am to 5:30 pm on Saturday, and from 10:00 am to 5:00 pm on Sunday, at the Kansas City Trade Mart. The Trade Mart is located at the Kansas City Downtown Airport, with easy access to all area interstate highways, with unlimited parking adjacent to the 45,000 sq. feet of exhibition space. Display booth spaces are available at a minimal cost of $15 for a single and $25 for a double. For further information, contact L. Charles Miller WAØKUH, 7000 Northeast 120th Street, Kansas City MO 64166, (816)-781-7313.

TRENTON NJ
APR 22

The Delaware Valley Radio Association and the Lawrenceville Amateur Repeater Group will hold their annual flea market on Sunday, April 22, 1979, from 8:00 am to 4:00 pm, at the New Jersey National Guard 112th Field Artillery Armory on Eggerts Crossing Road off Route 206 in Lawrence Township, Trenton, New Jersey. Advance registration is $2.00; $2.50 at the gate with tailgating $4.00 additional—bring your own table. The selling area is indoors and protected from the weather. There will be ample parking, refreshments, and restroom facilities. Talk-in on 146.52, 146.07/.67, and 147.84/.24. For further information and reservations, write D.V.R.A., PO Box 7024, West Trenton NJ 08628.

DIXON IL
APR 22

The Rock River Radio Club will hold its 13th annual hamfest on Sunday, April 22, 1979, at the Lee County 4-H Center, 1 mile east of the junction of Rts. 52 & 30, south of Dixon, Illinois. Advance tickets are $1.50; $2.00 at the gate. There will be indoor facilities, a camping area, free coffee and donuts from 7:30 am to 8:30 am, prizes, and breakfast and dinner available. Talk-in on 146.52 and 146.37/.97. For advance tickets, mail to RRRC Hamfest, Chuck Randall W9LDU, 1414 Ann Ave., Dixon IL 61021.

WORCESTER MA
APR 27

The Central Massachusetts Amateur Radio Association, Inc., will hold its auction and ham flea market on April 27, 1979, at the Main South American Legion Post 341, Main Street at Webster Square, next to Atamian Motors, Worcester, Massachusetts. The doors open at 6:00 pm, with the auction beginning at 7:30 pm. At the auction, 15% of the profits will go to CMARA. The flea market tables are $5.00 (items $5 and less only). Dealers are welcome. There will be door prizes, raffles, and refreshments available. Talk-in on 146.37-146.97 and .52. For more information, contact Rene Brodeur WA1LEA, (617)-753-7480, or Dave Penttila K1COW, (617)-885-4995.

WILLIAMSPORT PA
APR 29

The West Branch Amateur Radio Association will hold its 15th annual Penn Central Hamfest on Sunday, April 29, 1979, from 11:00 am to 5:00 pm at the Woodward Township Fire Hall, Rt. 220 south from Williamsport. For more information, write Richard Sheasley K3QDA, RD 1, Box 454, Linden PA 17744, or call Tony at (717)-322-6017.

SHREVEPORT LA
MAY 4-5

The Shreveport Amateur Radio Association will hold its annual hamfest on May 4-5, 1979, at the Louisiana State Fairgrounds. Pre-registration is $3.00; $4.00 at the door. This is an ARRL sanctioned hamfest.

NEENAH WI
MAY 5

The 3-F Amateur Radio Club will hold its annual swapfest on Saturday, May 5, 1979, from 8:00 am to 3:00 pm, at the Neenah Labor Temple, 157 S. Green Bay Road, Neenah, Wisconsin, just off Highway 41 at the Highway 114 or 150 exit. Facilities include a large parking area and a large indoor swap area with a free auction at the end of the day. Food and beverage will be available. Advance admission for tickets

Ham Help

I would like to contact any hams who practice transcendental meditation and would like to form a TM net—international, if possible.

Lee Ryan KB6IJ
1229 Park Row
La Jolla CA 92037

I am looking for information on the Level II BASIC kit for the TRS-80. I use the TRS-80 on RTTY and CW. I need the schematic points for the four-wire ribbon on the CPU board, the dip-shunt position after installation, and also for use of the enclosed resistor. I have the technical manual. I will gladly pay any postage or reproduction costs.

Jon J. Kilcoyne N8ACD
12824 Clyde Road
Fenton MI 48430

I am a high school teacher at the Stoneleigh-Burnham School in Greenfield MA, an independent boarding school for girls in grades 9-12. Many students here have expressed great interest in communications and are quite anxious to establish a ham radio club of their own. Many of the girls are avid shortwave listeners and are ready now to move up and get their Novice licenses.

If there is any individual or organization with extra or unused ham gear who would be able to make a tax-deductible donation to the school to start such a club, we would appreciate it if they would please write. We would like to pay all shipping and packing costs. Many thanks.

Jerry Nevins
Stoneleigh-Burnham School
Greenfield MA 01301

and tables is $1.50; $2.00 at the door. Talk-in on 52/52. For reservations, write to Mark Michel W9OP, 339 Naymut Street, Menasha WI 54952.

DEKALB IL
MAY 6

The Kishwaukee Radio Club and the DeKalb County Amateur Repeater Club will hold their 21st annual indoor/outdoor hamfest on Sunday, May 6, 1979, from 8:00 am to 3:00 pm at the Notre Dame School, 3 miles south of DeKalb between highway 23 and South 1st St. on Gurler Rd., DeKalb, Illinois. Tickets are $1.50 in advance; $2.00 at the door. Indoor tables are available or you may bring your own. The outdoor setup is free. Talk-in on 146.13/.73 and 94. For tickets and directions, send an SASE to Howard Newquist WA9TXW, PO Box 349, Sycamore IL 60178.

WARMINSTER PA
MAY 6

The Warminster Amateur Radio Club will hold its fifth annual "Ham-Mart" flea market and auction on Sunday, May 6, 1979, from 9:00 am until 4:00 pm, at the William Tennent Intermediate High School, Street Road (Route 132), two miles east of York Road (Route 263), Warminster, Bucks County, Pennsylvania. A registration fee of $1.00 per car includes one ticket for door prizes. Tailgating is $2.00 additional. Indoor tables are available for $3.00 each. Talk-in on 146.16/76 and 146.52. For further information, please write Horace Carter K3KT, 38 Hickory Lane, Doylestown PA 18901, or phone (215)-345-6816.

FRESNO CA
MAY 11-13

The 37th annual Fresno Hamfest will be held on May 11-13, 1979, at the Sheraton Inn, Clinton and Highway 99, Fresno, California. The program includes technical talks, swap tables and flea market, transmitter hunt on 2 meters (146.52), QLF contest, ARRL CD appointees meeting, ARRL-FCC forum, commercial exhibits, prizes, eyeball QSOs, prime rib banquet, and more. For full registration and eligibility for pre-registration prize, send in $17 before April 27, 1979; it's $19 and no pre-registration prize after that date. Talk-in on 146.34 /146.94. For more information, contact the Fresno Amateur Radio Club, Inc., PO Box 783, Dept. HF, Fresno CA 93712.

DEERFIELD NH
MAY 12

The Hosstraders Net will hold its 6th annual tailgate swapfest on Saturday, May 12, 1979, at the Deerfield Fairgrounds, Deerfield, New Hampshire. There will be covered buildings, in case of rain. Admission is $1.00, with no commission or percentage. Commercial dealers are welcome at the same rate. Excess revenues will benefit the Boston Burns Unit of the Shriners' Hospital for Crippled Children. Last year we donated over $1100.00. Talk-in on .52 and 146.40-147.00. For more information, send an SASE to Joe DeMaso K1RQG, Star Route, Box 56, Bucksport ME 04416, or Norm Blake WA1IVB, PO Box 32, Cornish ME 04020, or check the Hosstraders Net on Sundays at 4:00 pm on 3940 kHz.

SALINE MI
MAY 13

The ARROW Repeater Association will hold its annual Swap and Shop on Sunday, May 13, 1979, at the Saline, Michigan, fairgrounds. Admission, including parking on the fairgrounds, is $1.50 in advance and $2.00 at the door. There will be food, prizes, and a covered area for trunk sales, as well as indoor tables. Because of Mother's Day, wives will be given free admission. Talk-in on 146.37/97, 223.18/224.78, and 448.5/443.5 MHz. For additional details, write ARROW, PO Box 1572, Ann Arbor MI 48106, or call George Raub AD8X at (313)-485-3562.

CADILLAC MI
MAY 19

The Wexaukee ARA will hold its 19th annual swap and shop on Saturday, May 19, 1979, from 9:00 am until 4:00 pm at the National Guard Armory, 415 Haynes Street, Cadillac, Michigan. Tickets are $2.00. There will be free parking and lunches available. Talk-in on 146.37/.97. For more information, contact Robert Bednarick WD8RZL, Publicity Director, Wexaukee ARA, Cadillac MI 49601.

BIRMINGHAM AL
MAY 19-20

The Birmingham Amateur Radio Club will hold Birminghamfest '79 and the Alabama State Convention on May 19-20, 1979, at the Birmingham-Jefferson Civic Center Exhibition Hall, Birmingham, Alabama. There will be many of last year's exhibitors, including most major manufacturers and distributors. There will also be a huge indoor flea market, lots of exhibit space, meetings, forums, activities, and plenty of free parking. Plans are being made to again offer on-site FCC exams on Saturday morning. Prizes will feature at least three complete HF stations, several VHF rigs, and a home video tape recorder system. The Saturday night banquet will feature the nationally known comedian and Grand Ole Opry member Jerry Clower. Banquet tickets will be available in advance, by mail, while they last. For more information, write Birminghamfest '79, PO Box 603, Birmingham AL 35201.

DURHAM NC
MAY 19-20

The Durham F.M. Association will hold its annual Durhamfest on Saturday and Sunday, May 19-20, 1979, at the South Square Mall, Durham, North Carolina. Plenty of prizes, exhibits, and programs will be offered, and the XYLs can enjoy shopping. Ladies' bingo will be held on Sunday. Free tailgating spaces, under a covered, drive-in-and-sell flea market, come with a one-time $3.00 general registration ticket, with vendors and dealers included. Electrical power will be available. Harmonics and unlicensed XYLs are admitted free. Talk-in on 147.825-.225, 146.34-.94, 222.34-3.94. For more information, write DFMA, Box 8651, Durham NC 27707.

BURLINGTON KY
MAY 20

The Kentucky Ham-O-Rama will be held on May 20, 1979, at the Boone County Fairgrounds, Burlington, Kentucky, For easy access, take the Burlington exit off I-75 south. There will be a chance for prizes included with the $3.00 gate ticket. There will also be hourly drawings, exhibits, a flea market, and refreshments. Talk-in on 146.19/79 and 52/52. For more information, contact NKARC, Box 31, Ft. Mitchell KY 41017.

UPPER HUTT NZ
JUNE 1-4

The 1979 Annual Conference of the New Zealand Association of Radio Transmitters will be held on June 1-4, 1979, at Upper Hutt, New Zealand. Visitors are welcome to attend this conference. For registration forms, contact the Secretary, 1979 Conference Committee, PO Box 40-212, Upper Hutt NZ.

WEST HUNTINGTON WV
JUN 3

The Tri-State ARA will hold its 17th annual hamfest and family picnic on June 3, 1979, starting at 10:00 am, at the Camden Amusement Park, West Huntington, West Virginia. There will be a planned program for the XYL and kids, or you can enjoy the amusement park if you prefer. There is a possibility the FCC will administer amateur exams. There will be major prizes, a large flea market, exhibitors, and displays. Dealers are always welcome to space in the covered pavilion. Talk-in on 34/94 or 16/76. For more information, write TARA, PO Box 1295, Huntington WV 25715.

MANASSAS VA
JUN 3

The Ole Virginia Hams A.R.C., Inc., will hold the Manassas Hamfest on Sunday, June 3, 1979, at the Prince William County Fairgrounds, ½ mile south of Manassas, Virginia, on Route 234. There will be indoor and outdoor exhibit areas, dealers and manufacturers, and tailgaters. Also, included will be plenty of parking, prizes, an FM clinic, breakfast and lunch, a YL program, and children's entertainment.

SENATOBIA MS
JUN 9-10

The fourth annual Tri-State Hamfest will be held on June 9-10, 1979, in the coliseum of Northwest Junior College, Senatobia, Mississippi. Indoor air-conditioned space will be available for manufacturers, dealers, and distributors. For information, contact Joel P. Walker, 1979 Hamfest Chairman, PO Box 276, Hernando MS 38632; (601)-368-5277.

BELLEFONTAINE OH
JUL 1

The Champaign Logan Amateur Radio Club, Inc., will hold its annual hamfest on Sunday, July 1, 1979, at the Logan County Fairgrounds, South Main Street and Lake Avenue, Bellefontaine, Ohio. There will be free admission and door prizes. Trunk and table sales are $1.00, and there will also be a bid table. Talk-in on 146.52. For more information, contact John L. Wentz W8HFK, Box 102, West Liberty OH 43357, or Frank Knull W8JS, 402 Lafayette Ave., Urbana OH 43078.

Corrections

In addition to the corrections on page 171 of this month's issue, it is felt that a further clarification is in order. Also in "Light Up Your Life" (December, 1978, page 137, column 2, lines 36-38), the pin connections might have been better explained this way: Connect *readout* pins 3 and 14 and *IC* pins 16 to 5 volts. Pin 8 of the ICs should go to ground.

Chamber of Horrors

—a true story

"We'll never see him again."

Stanley O. Coutant WB6WFI/LB
248 San Gabriel Ct.
Sierra Madre CA 91024

This was the summer I was going for the amateur Extra. It had been put off far too long. Besides, the new comprehensive code test would make it easy. Wait—that can't be me talking. Or have I finally cracked under the strain? That must be it—to even think the Extra could be easy.

After two weeks of daily study, the situation looks a bit more promising. Maybe I will try after all. At least I'll see what it's like, in preparation for the second attempt.

Okay, this is it. Do or die. Now or never. The cliches don't provide any comfort. The car seems colder than usual. The sky gloomier. My pulse rate is definitely increasing. The car's clock shows 6:05; the sun barely clears the mountains to the east as I back out of the driveway.

I arrive at 7, and already three or four others are either sitting in their cars or pacing out in front of the building. At 7:30 the street-level doors are unlocked, and a brief elevator ride brings us to the fateful floor where we set up camp to await the arrival of 8:00 am.

At 7:55, a lady sticks her head out of a certain doorway we have been studying and says, "All right, I want all the 20-word-per-minute people. . . those going for Extra Class only." I look around at the growing group of about 15. No one moves. I am the only one!

I steady myself against the wall, telling my rubber knees they'll have to do better, and follow her into the reception area amidst comments of "Been nice knowing you," and "We'll never see him again."

The lady and I stand in the still-dark reception lobby. She re-locks the door. I swallow hard. She walks around the desk, turning on the lights in the process. After opening the log at the appropriate page, she asks me to sign in. I am number one. The page is clean, except for the date at the top and the figures down the left margin. I can barely write. I am thankful I had typewritten my Form 610 application the night before.

After the paperwork is complete, the receptionist presses a button and a nasty 60-Hz buzz fills the room. I expect the floor to open beneath my feet, and I try to recall what I know about crocodiles. When the floor remains solid, I decide it is only the locking device on the door to the inner sanctum. I enter. There at the first desk is another lady, sharpening her fingernails. At the second desk is . . . a stranger! The fellow who administered my General and Advanced Class exams is nowhere to be seen! This ferocious-looking fellow is limbering up his "FAILED" rubber stamp with one hand and sorting through a box of cassette tapes labeled "Fast," "Faster," and "Ridiculous" with the other.

I take a seat in the still-empty glass chamber—the first seat, nearest the door.

The buzzer sounds again, and the other applicants begin filing in. And filing in. And still more, until the room is filled— 61 of us in all! Amidst all this humanity are two other Extra Class applicants who have turned up—one a General, the other a Novice of three months!

The examiner appears, grinning diabolically, with three sets of wireless headphones in his hands. "Who are the Extra Class applicants?" he asks. We foolishly raise our hands. He distributes the aforementioned instruments of torture.

"All right, you will hear one minute of practice code which you may copy if you wish but it won't count on the exam followed by five minutes which is the test after which you will hear the procedure signal AR at which time I will hand out questionnaire booklets with five multiple-choice answers per question from which you will select the correct answer and indicate your choice on the answer sheet in the proper box corresponding to the question number. Make no marks in the questionnaire booklets, only on the answer sheets. Are there any questions?"

The receiving test

begins. VVV VVV Got it. Solid copy so far. Hmmm. Sounds like a QSO I had the other night on 80 meters. Nice fist. Not bad at all. What? AR already? I don't believe it. The test is over? There must be some mistake. The examiner must have hooked us up to a receiver on 40 meters instead of the tape machine.

Here he comes, questionnaire booklets in hand, ready to be distributed. The 58 other applicants look on; expressions of sympathy and compassion are evident.

I read the first question. Easy. I've heard of these "buffer question" techniques. The answer is right there. The second question is equally simple. Two buffer questions out of 10? What is the Commission coming to? The third . . . the fourth . . . so obvious! I must be going to wake up soon, at home in my own bed.

The questions have all been answered. A double-check turns up no problems. Oh, well, I probably put the wrong letters in the boxes on the answer sheet.

Here comes the examiner again. Our papers vanish. So does he. The three of us look at each other, not daring to speak. I want to say, "Howdja do?", but nothing happens.

The examiner reappears. "Would the three people who took the code test meet me at the back table, please." It is not a question. We cower on our way to the back of the room, as 116 eyes follow our feeble progress.

The examiner leans close. He whispers: "All three of you aced the receiving test. Under the circumstances, I think we can skip the sending test." Three jaws drop. The examiner smiles. "Congratulations." He shakes our hands.

We float back to our seats. Our smiles must be obvious, as the remainder of the group breathes a collective sigh of relief on our behalf.

But why am I smiling? The theory test . . . the examiner was only playing with us—toying with our emotions! His smile must have been due to what he remembered was yet to come, that which I had momentarily forgotten.

The written exams are distributed. The ordeal begins anew. Only 49 questions after this one. 48 . . . 47 . . . Wait a minute—this is familiar—a lot like what I studied the past two weeks. Not too shabby!

I'm finished—one way or the other. I submit my materials. "Wait in the lobby, please, until your name is called."

The lobby is filled with people! The receptionist is telling a recent arrival, "There are over a hundred applicants so far this morning. Please take a seat and wait to be called."

One hour and 20 minutes later, a clerk appears. She's the one who was sharpening her fingernails earlier. She is carrying a handful of exams and application forms. "Anderson, you passed the Technician. Fill this paper out. Baker, you passed the Advanced. Fill this out, please. Coutant . . . let's see, yours was an Extra Class . . . hmmm . . . oh, here it is—you passed."

As she hands me my interim permit, I can't help but notice her smooth, nicely rounded manicure. She continues through the stack of papers, and we learn my fellow aspirants have both passed as well.

Outside, the sun, now high in the sky, has returned to its usual warm, bright self. It's a spectacular day! ■

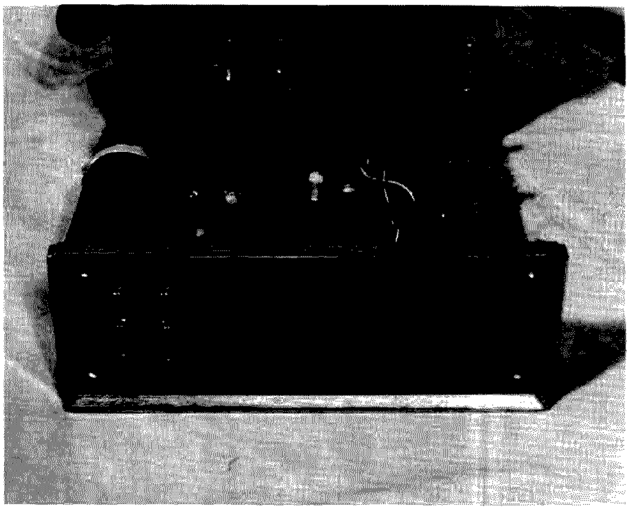
An Intelligent Scanner for the HW-2036

—it's programmable

Unique versatility.

Lawrence D. Schuldt WA9TAH
415 Wayne Rd., Rt. 1
Rochelle IL 61068

This article describes a programmable scanner designed to interface with the Heath HW-2036 transceiver, but capable of being modified to function with other transceivers using binary-coded-decimal synthesizer frequency control. This scanner also has a small instruction set to increase its versatility, a feature which I believe is unique.



View from front of scanner showing front panel layout with all indicators illuminated.

Overview

Frequency and channel number, along with other information, are presented to the user on an LED display. When the scanner's memory has control of transceiver frequency, the memory contents are displayed. When the thumbwheels control frequency, the LED display follows the thumbwheels. This has been found to be a

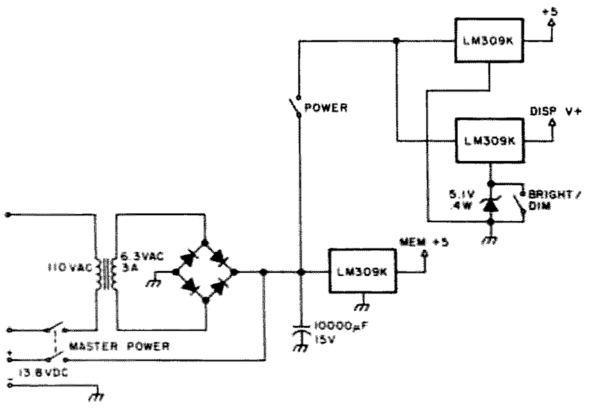


Fig. 1. Power supply.

Note on logic diagrams:

Total IC package count is 27. The numbering scheme is as follows. Components with numbers 100 and above are mounted on the display panel. Components numbered E1-E4 are in the first row on the board, E11-E14 in the second row, E21-24 in the third row, etc.

Not shown on logic diagrams are decoupling capacitors.

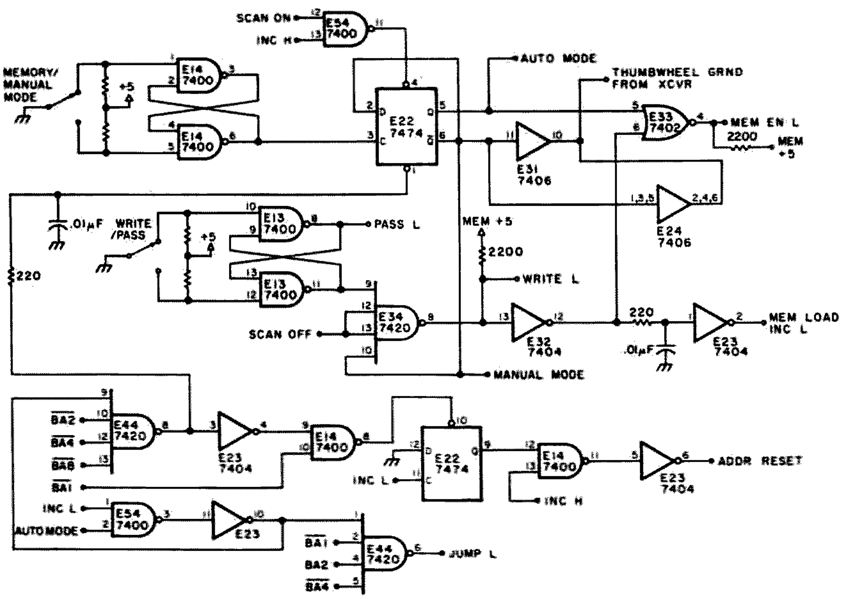

Fig. 2. Memory control and instruction logic. Resistors at E14-1, 5 and E13-10, 12 = 2200 Ohms.

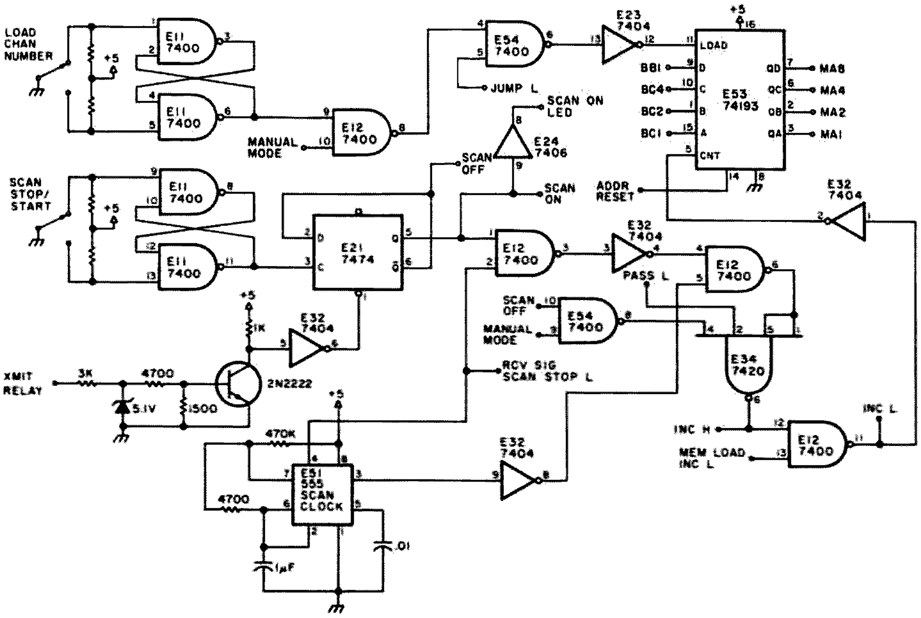

Fig. 3. Scan control logic. Resistors on E11 are 2.2k Ohms.

great convenience when driving at night, since the thumbwheels on the transceiver are not illuminated, which makes it difficult to read the frequency or to QSY without turning on the dome light. Other information displayed in the LED display is whether the scanner memory or the thumbwheels have control of transceiver frequency, whether scanning is turned on, and whether the fast or slow squelch delay is selected.

The scanner's memory is capable of storing 16 words. This memory data can be interpreted as either frequencies or instructions to be executed.

The instruction set consists of three instructions. Since all frequencies entered into the scanner will have either a 4, 5, 6, or 7 in the megahertz position, it was decided to use some of the unused digits as instructions. Therefore, the numbers 0, 1, and 2 are decoded and executed as instructions by the scanner.

The instruction set is as follows:

A zero in the megahertz position will cause the scanner to reference the thumbwheels for its frequency to be scanned, after which it will reset the channel counter to zero and begin scanning again from channel zero.

A one in the megahertz position will cause the scanner to read the thumbwheels for the frequency, but have no effect on the channel counter.

In this and in the previous instruction, the numbers in the 100 kHz and 10 kHz positions are irrelevant.

A two in the megahertz position will cause the scanner to execute a jump to the channel number specified in the 100 kHz and 10 kHz positions. If the memory contents were 204, the scanner would jump to channel 4. This instruction is used for storing more than one set of frequencies in memory. By simply starting the scanner in the appropriate set of frequencies, you have a choice of frequencies that can be scanned without reprogramming.

The instructions that reference the thumbwheels have been found to be very useful, since this gives you one channel that can be changed without reprogramming.

Examples of how the in-

struction set is used will be given later in the section entitled "Operation." It's not as complicated as it sounds.

The scanner can operate either from the 13.8 V dc mobile power or from its own internal ac supply. The Heathkit supply for the HW-2036 is not capable of supplying the current requirements for both the transceiver and the scanner, so a separate supply is required for the scanner.

The scanner was built to provide a reasonably close match to the Heath transceiver, but, of course, the builder can change packaging to suit himself. The cabinet and bezel are ordered from Heath and the chassis is the chassis from the HW-2036-3 power supply. The front panel is fabricated from a piece of scrap aluminum.

There are five push-buttons on the front panel which function as follows:

The SCAN push-button turns scanning on and off. Status is indicated by an LED on the front panel.

The MEM push-button gives you the option of memory-controlled frequency when not scanning Memory is automatically activated when scanning is started, so it is not necessary to press MEM at the start of scanning. Status of memory or manual frequency control is also indicated by an LED on the front panel.

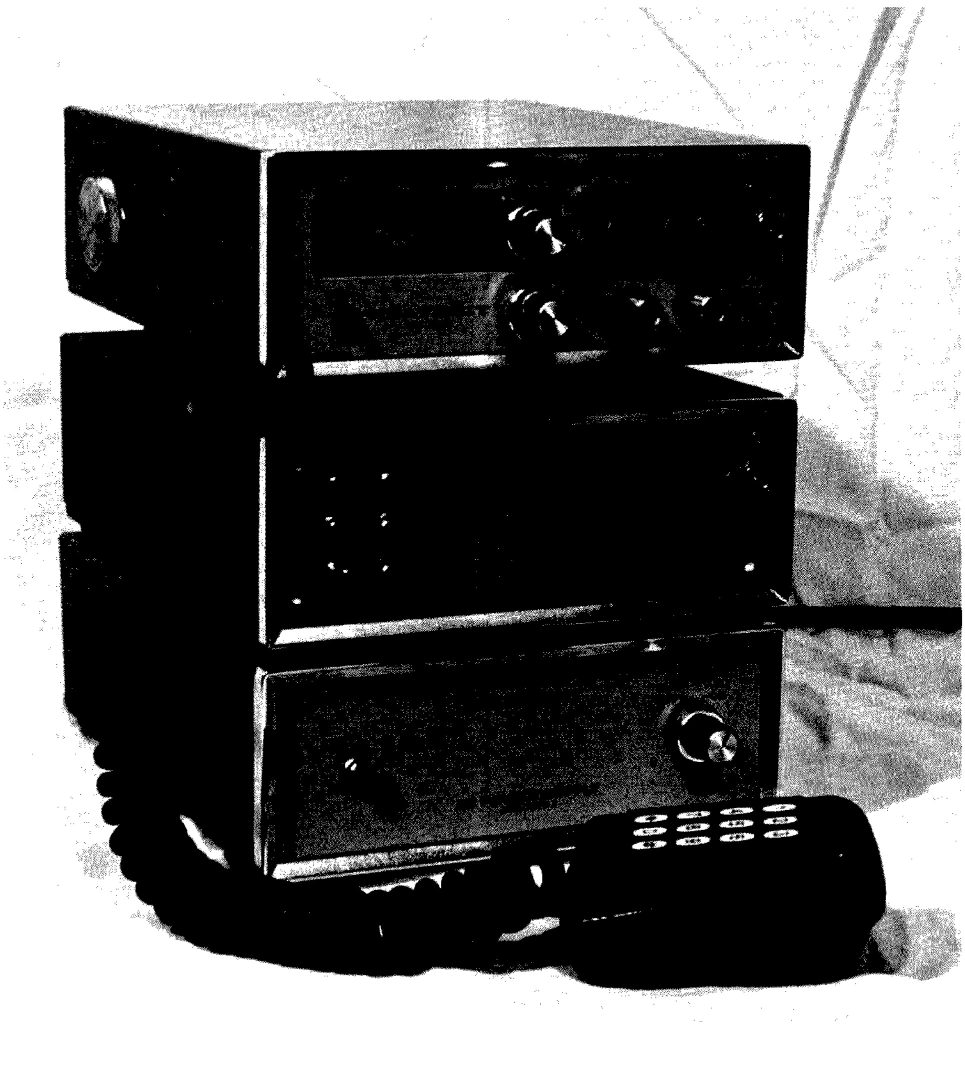
The LOAD CHAN button causes the value placed into the two right-hand digits of the thumbwheels to be transferred to the channel counter. This lets you address any location in memory for modification or for starting a scanning sequence. As has been previously mentioned, more than one scanning sequence can be stored in memory. The correct sequence is activated simply by starting the scanner at the first address (channel number) of the desired sequence. The channels are numbered octally (base 8) from zero to seventeen. The number sequence is, therefore, 0, 1, 2, 3, 4, 5, 6, 7, 10, 11, 12, 13, 14, 15, 16, 17. This is done because binary-to-octal and octal-to-binary conversions are much easier to do than binary-to-decimal and decimal-to-binary conversions.

The SQUELCH push-button selects one of two delays, after which scanning resumes when a carrier drops out of the receiver. The two delays are approximately 13 seconds and about .2 seconds. The 13-second delay is sufficiently long to prevent the scanner from resuming scanning before a reply is received. However, if you wish to resume scanning between exchanges of a QSO you are monitoring, switching to the .2-second delay lets you do so. The .2-second delay is long enough, however, that the scanner will not resume scanning if the signal drops momentarily because of mobile flutter.

The WRITE/PASS button serves, as the name implies, a dual function. When the memory and scanning are off, pressing this button will cause the contents of the thumbwheels to be written into memory. When the button is released, the channel counter will increment, ready for the next write.

When scanning, the WRITE/PASS button is used to cause the scanner to bypass a signal. In other words, when the receiver is locked on a signal and you wish to resume scanning, pressing this button will increment the channel counter and cause scanning to resume.

In addition to the five buttons, there are three switches associated with operation. The BRIGHT-DIM switch varies the intensity of the LED display from a low intensity suitable for



Overall view of the author's 2 meter FM setup with Heath power supply, WA9TAH scanner, and HW-2036 transceiver.

indoor use or mobile use at night or a not particularly bright day, to a high intensity that the sun at noon is hard put to wash out when operating mobile.

The power switch on the front panel removes power from the displays and all logic except for the memories. This way, as long as power is available, the RAMs retain their data.

The master power switch is located on the back of the scanner and removes all power within the unit.

Since momentary contact switches are used, some indicator system is required to display the key information on scanner status. For this purpose, the decimal points of the two digits in the channel indicator are used, plus one additional LED. The decimal point labeled MEM is used to indicate that the memory has control of the frequency. When this LED is lit, it is impossible to do a write into memory, since the thumbwheels are disabled.

The other decimal point in the channel indicator display is labeled FAST SQ. When this indicator is on, the squelch delay is set for the .2-second time.

An additional LED is located between the channel counter and the frequency display and is illuminated when scanning is turned on. The write function is disabled when this LED is lit also, so, in order to write into memory, both the SCAN and the MEM LEDs must be off.

One additional feature is built into the scanner; its function is to prevent the transceiver from scanning if you decide to QSO. The first time the push-to-talk button on the microphone is pressed, scanning is turned off. This is reflected on the display panel; when PTT is pressed, the SCAN LED goes out. Scanning can be restarted after the QSO by pressing the SCAN button.

Table 1. All 16 channels used as frequencies. With this sequence programmed in, the scanner will cycle through all memory locations repeatedly, starting again at channel 0 at the end of a sequence.

Operation

The following are some examples of how the scanner may typically be used.

The startup sequence is as follows:

With power on, the LED displays should light. The SCAN, FAST SQ, and MEM LEDs may be on.

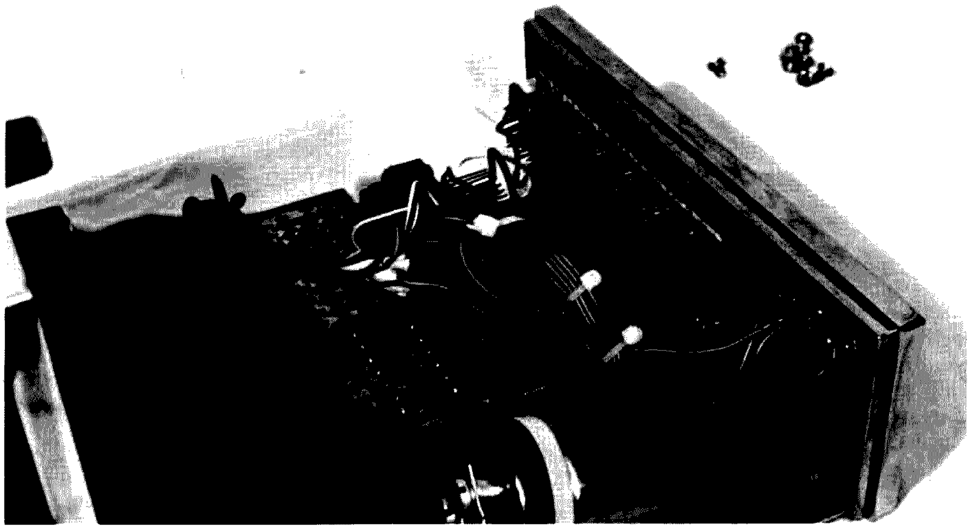
If the SCAN LED is on, press the SCAN button to turn it off.

If the MEM LED is lit, press the MEM button to turn it off.

Dial up the number of the first channel you wish to program in the two right-hand digits of the thumbwheels. Press LOAD CHAN, and the channel counter display should now read this value.

At this time, the scanner is ready for programming. To program, simply dial in the desired digits in the thumbwheels, and press the WRITE/PASS button. Each time the button is released, the channel counter should increment, awaiting the next write cycle.

When all frequencies and instructions are loaded into memory, dial the desired starting channel number into the two right-hand digits and press LOAD CHAN. The channel counter LEDs should display the number in the thumbwheels. Press SCAN and the scanner will begin scanning, changing frequencies, and executing instructions as it reads the memory information. If the programming included an instruction to read the thumbwheels, dial up a frequency in the thumbwheels. As you watch the LED frequency display, you will see the frequency in the thumbwheels being scanned, and the MEM LED will blink out, indicating that, at that time, frequency is being controlled by the thumbwheels.



Close-up view showing construction of front panel and some of the switch wiring.

Tables 1 through 3 are some typical programming examples, with explanations of what the scanner will do.

Logic

An attempt has been made to divide the logic diagrams into easily digestible (and drawable) units. These will be covered individually here.

The frequency display logic diagram consists of the LEDs for the MHz, 100 kHz, and 10 kHz digits, their 7447 decoder-drivers, and the 7404 inverter-buffers. The double inversion on each bit is not a mistake; it is there to reduce loading on the lines between the thumbwheels and the synthesizer board.

Fig. 7 shows the channel display logic for the two digits of the channel display, the SCAN LED, the FAST SQ LED, the MEM LED, and the two most significant digits of the frequency display, which are hard-wired to display a 1 and a 4.

The 7406 IC is a hex inverter-driver with open collector outputs. Four sections of E31 are used here to turn on segments in the left-hand channel display digits.

The heart of the scan control logic (Fig. 3) is the 74193 programmable up-down counter. In this case, only the count up input is used. The counter can be preset to any desired value by applying data to pins 1, 9, 10, and 15 and pulsing pin 11 low. This is how the jump instruction and the load channel functions are performed.

The count pulses for the 74193 are generated by E51, a 555-type timer IC wired in the astable configuration. This produces a string of clock pulses with a period of about 350 milliseconds.

Application of pulses from the scan clock to the counter is enabled by the scan enable flip-flop, E21-6, and the signal RCV SIG SCAN STOP L, which stops the scanner in the presence of a signal. E21 can be set or cleared by pressing the SCAN push-button, and E21 can be cleared by voltage at the transmit relay going to zero, as it does when PTT is pressed.

Two other signal sources for incrementing the channel counter are included. They are PASS L, which is asserted when the WRITE/PASS button is pressed and memory or scanning are turned on, and MEM LOAD INC L, which is asserted when the WRITE/PASS button is pressed and memory and scanning are turned off. This causes the channel counter to increment after the write is performed.

Fig. 2 shows the memory control and instruction decoding logic. The main element in the memory control logic is flip-flop E22-5, 6. This is the memory/manual mode control. When the flip-flop is set, a ground for the thumbwheels is broken, removing them from control of the synthesizer, and the signal MEM EN L is generated to the memory, turning it on and giving the memory control of the synthesizer input lines. This flip-flop can be set and cleared by the MEM push-button on the front panel. It is also set by the signal INC H, which is derived from the scan clock when scanning is turned on. It can be cleared by either a 0 or a 1 instruction, which tells the scanner to scan the frequency in the thumbwheels.

Another part of the memory control logic is the WRITE/PASS logic. PASS L is generated whenever the WRITE/PASS button is pressed, but is inhibited from doing anything unless scanning is on or memory is on. This in-

Channel	Contents	Comments

17	2.11	jump to channel 11

Table 3. Multiple sets of frequencies, each of which can be individually selected. This sequence contains three separate groups of frequencies and instructions. Starting the scanner at channel 0, 1, 2, or 3 activates the scanner in the first loop. Similarly, starting the scanner at channel 4, 5, 6, 7, or 10 activates the second loop. If the scanner is started at channel 11, 12, 13, 14, 15, 16, or 17, the third loop is entered.

When a signal is encountered, the scanner will stop scanning. When the signal drops, the scanner will resume scanning after either the 13-second or the .2-second delay. If you wish to engage a station heard in a QSO, simply make sure that the offset switch on the transceiver is set to the appropriate offset, pick up the mike, and go. Transmit frequency also follows the scanner.

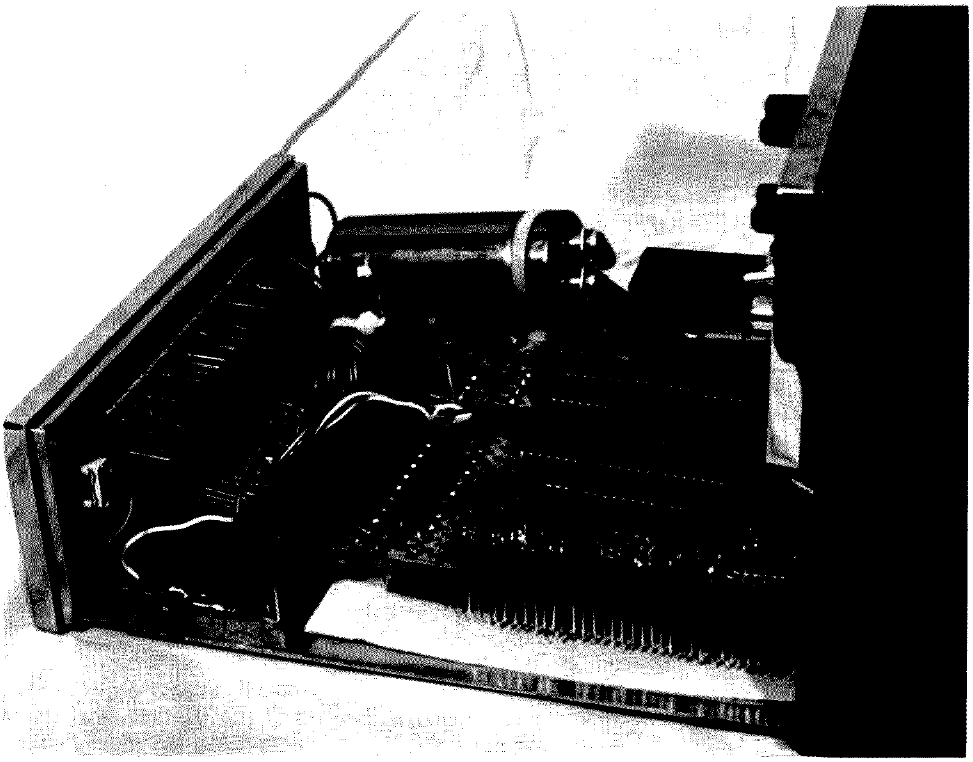
There is one limitation on the instruction set. Do not follow a jump instruction with another instruction, only a frequency. For example, if a memory location contains 2.04, channel four should not have a 1.XX, a 0.XX, or another jump instruction in it. If this is attempted, the instruction following the jump may not decode reliably. Putting a frequency, which requires no decoding, after the jump instruction is perfectly legal, however.

hibit gating is on the channel counter logic diagram, E54-8. When scanning is off and the thumbwheels are in control of the synthesizer lines (also used as the memory input/output bus), it is possible to do a write into memory. In this condition, E54-8 inhibits the PASS L signal from incrementing the channel counter. E34-8 is enabled when the WRITE/PASS button is pressed and the signal WRITE L is generated. This signal is also used to generate MEM EN L, which turns on the memory without giving it control of the synthesizer lines. In this manner, the thumbwheels retain control of the synthesizer lines, and what is dialed into the thumbwheels is written into memory.

Shortly after WRITE L returns to a high condition, MEM LOAD INC L goes low, causing the channel counter to increment for the next write cycle.

The only portion of the logic in this diagram not discussed so far is the instruction decoding logic. Instruction decoding is enabled at E54-3, requiring that we must be in auto mode, that is, the memory must have synthesizer control in order to decode an instruction. This prevents any attempts by the scanner to execute instructions when merely dialing a 0, 1, or 2 into the thumbwheels. The instruction must be read from memory to execute. Instructions are also inhibited from executing until the signal INC L returns to a high state. Since data is brought out from memory on the negative-going edge of INC L, this ensures adequate setup time for proper decoding.

Decoding for the jump instruction is the simplest. E44-6 examines the data from the most significant digit of memory, and, if it is 2, generates JMP L. Note



Close-up view of scanner interior from the left. Discrete components are shown mounted on 16-pin DIP plugs.

that this instruction executes immediately upon INC L going high. This means that after the jump instruction is executed, there will not be another INC L pulse. Thus, if another instruction is present, there is no setup time available, and an instruction will execute as soon as it is marginally decoded. This can lead to very erratic performance, and I have found it best simply not to follow a jump with another instruction.

E44-8 examines the most significant digit in memory and asserts a low if a 1 or a 0 is detected. Since both of these instructions are used to cause the scanner to read the frequency in the thumbwheels, this signal is used to clear the memory/manual mode flip-flop. This places the thumbwheels in control of the frequency until the next INC H pulse.

Additionally, if the instruction decoded is a 0, this will be detected by E14-8. This will set flip-flop E22-9, which serves as a memory for this instruction during the time that the thumbwheels have control of the synthesizer. When INC H goes high, the output of the flip-flop is enabled through E14-11 to become the signal ADDR RESET, which clears the channel counter. At the same time, INC L goes low. When INC L returns to the

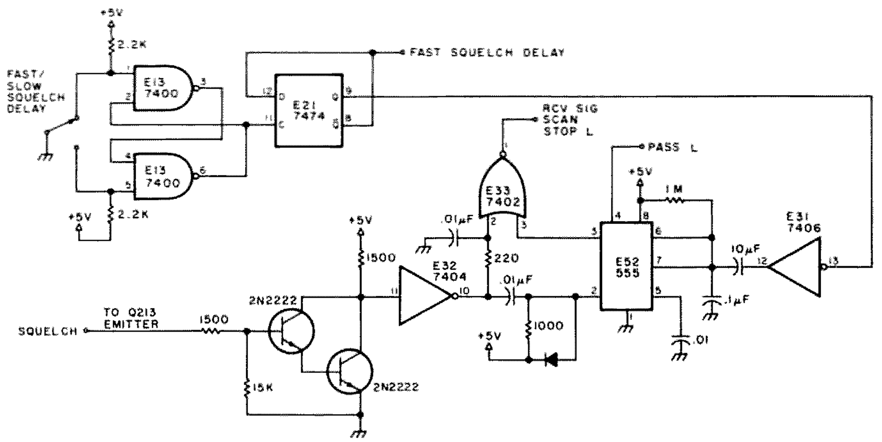


Fig. 4. Fast/slow squelch.

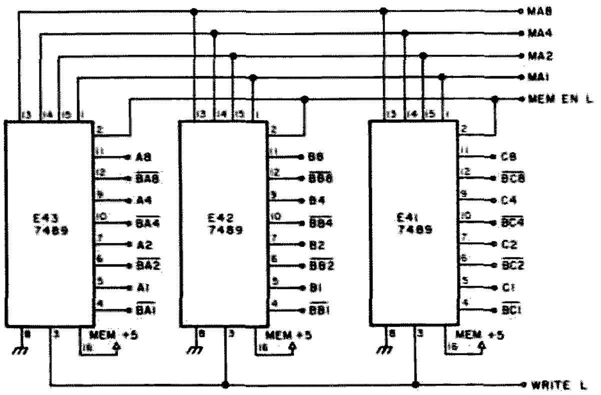

Fig. 5. Memory.

high state, it clocks and clears the flip-flop, restoring it to its original clear condition.

The squelch control logic is relatively simple. The squelch voltage is converted to a TTL logic level* and is used to generate the signal RCV SIG SCAN STOP L. When the squelch voltage returns to the squelch state, this triggers the 555, E52, wired as a monostable. This holds RCV SIG SCAN STOP L asserted for an additional time interval. The selection of the 13-second or the .2-second time delay is performed simply by using E31-12 to switch in additional capacitance for the longer time period.

After the amount of logic required to support it, the memory itself is anticlimactic. There are three memory ICs, each storing 16 words 4 bits long. Certain signals are bussed in common to all three chips. They are MEM EN L, which turns on the memory for a read or write, MA1, MA2, MA4, and MA8, which control memory addressing and are generated by the channel counter, and WRITE L, which, when asserted, causes the data on the input lines to be written into memory.

As can be seen in Fig. 1, there is nothing fancy about the power supply, and it shouldn't cause anyone any problems.

Transceiver Modifications

In order to interface this scanner with the transceiver, a few minor modifications are necessary. They are quite simple and should pose no problem. First the thumbwheel contacts must be isolated from each other. To do this, a diode is placed in series with each wire from the thumbwheels to the synthesizer board. The cathode ends of the diodes are connected to the thumbwheels and the anode ends are connected to the synthesizer board. This isolates the switch sections so that, when the memory has control of the bus, data bits are not shorted together by the switches. I recommend germanium diodes for this purpose because of their lower forward voltage drop. For the Heathkit transceiver, this will require 12 diodes.

The ground wire from the thumbwheels must also be lifted and extended into the scanner. This becomes the signal THUMBWHEEL GND on the logic diagrams. When this is grounded, the thumbwheel data is asserted onto the bus. When this is broken, all data inputs to the synthesizer go to a high state and the memory can then assert control.

Two other wires are required. One goes to the cold side of the transmit/receive relay coil. In the receive position, this is at

13.8 volts. When transmitting, it is grounded. The other wire is a pickoff for squelch voltage and, in the Heath transceiver, goes to the emitter of Q213. For other transceivers, it may be necessary to vary component values, add a zener diode in the squelch line, or eliminate the inverter at E32-10. This will vary from one make and model to another, so no specifics for other rigs are offered here.

There are a total of 15 conductors between the scanner and the transceiver, not including ground, which is made through the cases.

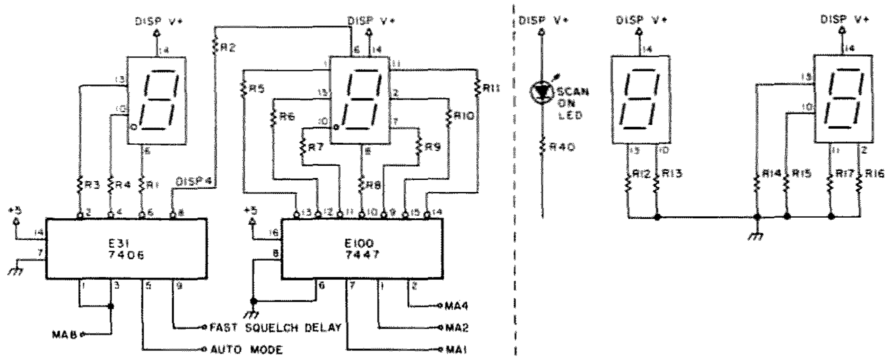

Fig. 7. Channel display.

Construction

The logic is built with wire-wrap techniques on a scrounged wire-wrap board. The display panel is built on a piece of perfboard with the 40 current-limiting resistors for the LEDs epoxied to it. Discrete components are mounted on DIP plugs which then plug into sockets on the wire-wrap board. I will be happy to answer any questions anyone may have that are accompanied by an SASE.

Possible Modifications

There are a number of possible ways a builder may wish to customize this circuit, so I'll mention a few. Scan rate could be made variable by using a pot. It could also be made asynchronous so that the channel counter would increment, wait for the synthesizer to achieve lock, time out a specified delay — maybe 50 to 100 milliseconds — and then increment again. Scan rate would then depend on how fast the synthesizer locks up rather than a fixed rate.

The builder may also consider putting pots on the squelch delay and in the LED brightness circuits. I didn't because most of my operating is mobile and I didn't want any more knobs to twiddle than necessary.

You may want to use a reed relay to tie thumbwheel ground to ground. I used four sections of a 7406 IC paralleled so that I could get the voltage drop as low as possible. Remember that the synthesizer board has to be able to detect a logic 0, and there are a diode and the 7406 IC producing voltage drops in series. I've had no problem with ambiguous voltage levels in this respect, but, if you have a reed relay in the junk box, there's a good place to use it.

Acknowledgement

I'd like to acknowledge the assistance of Tom Cronick WB9YVY for his help in fabrication of some of the parts of this scanner, and Brian Herzog WD5GYS for the photography.■

Trickle-Cost Trickle Charger

—junk-box project

1947 revisited.

Carl C. Drumeller W5JJ
5821 NW 58 St.
Warr Acres OK 73122

A catchy title, huh? What it really means is that you can build a trickle charger for just about zero cost. This one was for a 12-V lead-acid storage battery in a recreational vehicle that sits idle for considerable periods. It belongs to one of my sons, and one day he came up with, "Hey, Dad, do you remember that trickle charger you built for the Mercury back in 1947? Could you build me one like it?" What a memory that boy has!

Yes, I remembered it . . . and yes, I could build one like it. The original was a zero-cost project, and the reproduction would fall in the same category.

A bit of pawing through what remains of my once extensive junk collection (I've given away two truck loads!) revealed a transformer with three 5-volt windings. There's nothing sacred about the total voltage needed from the transformer. Anything above about 15 volts and below about 35 volts can be used. The hyper-simple method of controlling the charge rate can cope with a wide range of ac voltages.

The three windings were hooked in series-aiding. Yes, there's "polarity" to ac . . . use a voltmeter to ensure series-aiding and not series-bucking! A bit more digging in the junk heaps produced an ancient base-mount socket for a light bulb. Sniffing through my diode collection nosed out one with a 3-A rating; one with a lesser capability would have served quite well.

Now for the circuit.

What could be more simple! All that remains is to ascertain the size of the light bulb you'll need for the desired charge rate. Here my multimeter came into use. Starting with the 10-A range and with a 25-W bulb in the socket, the charger was hooked across a 12-V battery. The meter barely moved. A milliampere meter was substituted. It showed about 35 mA, a bit on the light side. Other light bulbs were tried, revealing that the charge rate could be varied from a few milliamperes to over an Ampere just by swapping bulbs. The size bulb you might need will depend upon what voltage your transformer produces plus what charging rate you desire. A few moments of trial-and-error will show just what you need. Be sure you start with a low-wattage bulb, or you might end up with a popped diode or a bent needle!

Other than that small precaution, it's a foolproof project, one providing a useful product at a very minimum cost. Try it! ■

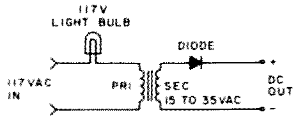

Fig. 1.

Reader Service—see page 211

Looking West

from page 6

No one can hurt you there. In fact, you stayed away from purchasing a 220 radio because of all the ongoing hoopla over 220 CB. Why should you give a damn about what happens to 220?

You have got to care. If this theft of 220 is successful, then your days of sanctity are numbered. A very evil precedent has been set here, one with far-reaching implications. If maritime mobile can be successful in convincing the military to give up spectrum, it would open the door for other services to do likewise. It's no secret that aircraft would love 144 to 148 MHz and remote broadcasting would be overjoyed to procure 420 to 450 MHz. The door is now open for them to lobby to that end. Even the low bands are not safe since there are always more services wanting spectrum than spectrum available. Do not be surprised to see the amateur media in the near future filled with just such stories. That is, unless the current situation can be beaten down in a way that will make the next spectrum thief think twice about going up against us.

WHAT MIGHT BE DONE

In gathering input for a Westlink item on this story, I placed calls to several coordination councils to gather reaction and input. Normally I wait for such calls to come to me, but this time the story seemed to warrant the expense. The reactions I got ranged from resignation that 220 was lost, to "we had better start moving repeaters off the band now so that there is no real crunch later," to "fight it to the wire" and beyond. These were the up-front emotional responses, but in most cases they were given with a sense of commitment.

Constructively, what can you as an individual do to stop this theft? Letters are important, as are petitions. Write your congressman and senators. Explain your feelings on the matter, and back this up with facts about amateur radio's projected growth and use of the spectrum over the next few years. To a politician these numbers mean votes, and every vote lost means less chance of his or his party's reelection to that office. Letters directly to the President might not hurt either.

Petitions hold the same or a greater value. Each signature is a potential vote, so if you circulate a petition, be liberal on the matter and get support from the general public as well as your fellow hams. The effect that a couple million signatures would have on the politicos would amaze you.

One avenue which is being explored is going on the offensive rather than staying on the defensive. There is talk of taking the initiative and going after 216 to 220 MHz as an addition to 220 to 225 MHz, in light of the fact that the government no longer has interest in its utilization. The rationale here is that (at least in southern California) 220 to 225 MHz is overflowing with activity and the 216-to-220-MHz spectrum would be able to handle the overflow from both 220 and two meters. At least one amateur I know is writing a direct request for rulemaking to the FCC on that very topic.

Finally, there is one more thing you can do. If you have been thinking of getting on 220 and now again fear the loss of the band, do not let this latest attempt at spectrum theft deter you. Now, more than ever before, it is important to populate 220 to the bursting point. Make the band overflow with activity. There is still time to make 220 into a band that would be very hard to change. 220 radios of the crystal-controlled variety are not expensive, and with the overall low noise floor of the band, the point-to-point simplex range will amaze you. You do not need a repeater to enjoy the advantages of this band.

REHAB RADIO DEPARTMENT

April Moell is a physical therapist at St. Jude's Hospital in Fullerton, California. She also happens to be a licensed amateur with the callsign WA6OPS. If you are fortunate enough to meet April in person, one thing becomes immediately evident: she loves people and loves being a ham. I guess it had to happen that April would eventually find a way to combine her two vocations into a new type of therapy: "rehab radio."

April is not trying to make her patients into amateur operators. I doubt if she would mind that happening, but if it ever does, it will be but a welcome by-product of the rehab radio program. You see, the basic purpose of rehab radio is to give severely ill or injured persons who must be hospitalized for long periods of time a "will" to recover. As it was explained to me, many times a person who is in the hospital for a prolonged stay loses track of the world outside the hospital walls. The hospital is a "safe" place, and it is easy for someone seriously ill or injured to retreat within himself in that environment. Rehab radio tends to counter that by placing the patient in contact with those outside his place of confinement. Being able to speak with a total stranger whose tone of voice says "I care" can have remarkable results.

It is the text of the QSO which is important—not the basic contact itself. To quote April: "Do not worry about chasing DX. Patients are not impressed by waiting through pileups to hear a signal report from the Isle of Yap. Also, you must keep in mind the third party agreement. Patients are quite impressed by working someone on the other side of the United States or someone in a state where the patient used to live. It is the person who is at the other end who is important, not his or her QTH."

On the day that I was there, a contact was made with a station in Alaska. I do not remember that station's call at this time. After establishing contact, April explained to the station exactly what was going on and then introduced each patient to the station at the other end. Our friend in Alaska spent quite a bit of time giving his greetings to each patient. As he did, each one either smiled or expressed an obvious sense of joy in some way. When "radio time" was about over, April again passed the mike around so that each patient could bid farewell to his newfound friend in Alaska.

If this interests you, you can get more information on the rehab radio concept by sending an SASE to April Moell WA6OPS, c/o St. Jude's Hospital and Rehabilitation Center Amateur Radio Association, 101 E. Valencia Meas Drive, Fullerton CA 92635. April has prepared a two-page information sheet that outlines the major points of how to get a rehab radio project started and lists related activities and how they can help patients. Please don't forget the SASE. You might also include a QSL card, since the rehab radio patients at St. Jude's really enjoy receiving them.

FLYING 220 AND OTHER PLACES REVISITED DEPARTMENT

As a result of publishing the story of one amateur's cross-country flight while SWLing on 220 MHz, we have received quite a bit of mail. Most of it had a Xerox® copy of an editorial written by Jim Fisk W1HR which appeared recently in *Ham Radio* magazine. Mr. Fisk pointed out the many hazards of operating an amateur transceiver while in a commercial airliner. He also went deeply into the legalities or illegalities of such operation, and quoted the experience of one amateur who wished to operate while airborne. In that case, the amateur did receive permission to operate, but only after exhaustive tests of the radio by the airline and then only for that particular flight on that specific aircraft.

This interested me, since I have been told by a number of amateurs over the years that they had operated "air mobile" by obtaining the consent of the particular captain in command of a given flight. Had they been breaking the law unknowingly? I did a little of my own exploring into the federal regulations governing air-carrier operation. It turns out that the regulations specifically state that, other than certain exempted devices such as tape recorders and hearing aids, the use of electronic devices aboard aircraft in commercial air-carrier service is forbidden. Amateur equipment is *not* on the exempted list.

How about asking the captain for his permission? He is the man in command, isn't he? Not in this case. The regulations are very clear on this. He does not have the authority to permit you to use your radio. Only the carrier has that authority, and in this case "carrier" signifies the airline itself rather than "rf." Therefore, if you feel that you must operate from the wild blue yonder the next time you are whisked away on the wings of a 747, you had better plan well ahead. It may well take months or even years to obtain the permission you need, and the amount of red tape may well boggle your mind. I suggest that anyone giving consideration to such operation first obtain a copy of the October, 1978, *Ham Radio* and read Jim Fisk's editorial on page 4. It does tell it like it is.

My thanks to all who wrote and brought this matter to my attention. It's just this kind of interaction which makes LW what it is. Without you, it would not mean very much. With you, it means a lot. Thanks.

Ham Help

I need a schematic for a Measurements 80 signal generator and a service manual for an Icom 22A 2m transceiver. I will copy and return.

ITU 1979 WORLD ADMINISTRATIVE RADIO CONFERENCE (WARC)

Announcement of Proposals

The FCC adopted yesterday[1] a *Report and Order* announcing its proposals to amend the International Radio Regulations to be considered at the general World Administrative Radio Conference in September 1979.

The FCC's *Report and Order* in this proceeding comes at the end of four years of inquiries in preparation for the general World Administrative Radio Conference (WARC). The Department of State will now use this *Report and Order* to prepare United States proposals which will be delivered to the International Telecommunication Union (ITU) in January 1979 for circulation among the nations of the world.

The ITU is an international organization of 154 member nations and has a history dating back to 1865. It is headquartered in Geneva, Switzerland. Through the ITU, nations cooperate in the use of telecommunications of all kinds to prevent interference, to provide common standards, and to promote the development of efficient technical facilities. It does this by several means, the most significant of which are: agreement among the member nations on a common set of international regulations [the function of Administrative Conferences]; agreement on common technical recommendations [the function of the international Consultative Committees (CCIR and CCITT)]; and registration of radio stations to avoid harmful interference [the function of the International Frequency Registration Board (IFRB)]. Each country participates on an equal basis.

The purpose of the 1979 (WARC) is to amend nearly the entire set of international Radio Regulations. These regulations consist of various definitions and operational and administrative requirements. The most extensive provisions are contained in a Table of Allocations which proceeds from one end of the radiofrequency spectrum to the other, and allocates various bands to defined "services." The Table is divided into three world regions. The Americas are contained within Region 2; Europe, Africa, and the Soviet Union within Region 1; and Asia, Australia, and the South Pacific within Region 3. Past General Administrative Radio Conferences were convened in 1927, 1932, 1937, 1947, and 1959. Numerous specialized Conferences have been held since the 1999 General Conference.

The FCC's Conference preparatory effort began in January 1975, with the issuance of a notice of inquiry, and establishment of a supporting Commission staff, including a Steering committee having overall management responsibility, and several specialized Functional Committees. In addition, the FCC created a number of industry advisory committees to serve as advocates for the various radio user groups through the preparation of reports and the filing of comments in this proceeding. During these past four years, the notices of inquiry have not only served to elicit public comment, they have also represented successive revisions in a process of refining FCC proposals.

Because the Radio Regulations affect all radio users, the Commission has coordinated all of its preparatory activities with the Department of Commerce/National Telecommunications and Information Administration (NTIA) [formerly the Executive Office of the President/Office of Telecommunications Policy (OTP)]. NTIA has the responsibility for coordinating U.S. government use of radio, which is managed by the Interdepartment Radio Advisory Committee (IRAC). IRAC established a 1979 (WARC) preparatory structure similar to that of the Commission's. Because of this ongoing coordination, the proposals adopted by the FCC are consonant with those of IRAC.

During this proceeding, thousands of United States citizens contributed their work and thoughts to the effort. Nearly 2,000 individual comments occupy almost 10 feet of file space. They range from those of a private citizen who saw his life impacted, to the massive reports of corporations and industry groups who saw their businesses potentially affected. The Commission is grateful for all these comments which, large or small, were considered and appreciated for the unique perspective which they afforded. Although the envisioned needs for radio spectrum exceeded the amount available, the FCC believes that in each case it has suggested a position which is equitable, in the public interest, and capable of being accepted by most of the ITU member nations.

The resulting Final Acts of the Conference will be in the form of a multilateral treaty and, in order to be binding, must proceed through the U.S. ratification process. Where the ITU Regulations impose a new affirmative obligation, the Commission will amend its Rules and Regulations to reflect the obligation. Where the ITU Regulations allow new allocations flexibilities, the Commission will, in appropriate future proceedings, consider the available options and offer them for public comment.

After the 1979 GWARC, there will be additional ITU Conferences which will also be of substantial importance to the U.S. Among them, the Plenipotentiary Conference [the equivalent of a constitutional convention] in 1982 has the power to consider and modify all major ITU institutional features. The Region 2 [Western Hemisphere] Broadcasting-Satellite Conference in 1983 will review the 12 GHz band allocations.

The FCC's underlying policy goal throughout this proceeding has been to minimize the international constraints placed upon the FCC in its domestic regulatory activities. Thus, it should be noted that merely because the FCC's GWARC position provided for the possibility of implementing a service in some band in the frequency spectrum, the Commission is not required in any future domestic proceeding to actually implement it.

Many of the FCC's proposals advocate increased sharing of frequency bands among radio services, as well as minimal administrative restraints on availability of radio spectrum and geostationary orbit allotments. This position of flexibility is particularly appropriate during the period of dramatic technological change which is foreseeable during the next two decades. The FCC believes that such a posture benefits not only the United States, but all ITU members.

Some of the highlights of the FCC's proposals include:

Proposing the expansion of the AM broadcasting band. The expansion would create a band at 1615-1800 kHz which is shared between broadcasting and various other services, and a band at 1800-1860 which is exclusively allocated to broadcasting. This change could result in approximately 14 new channels [or approximately 700 new AM stations]. Because most of the available broadcasting channels have been alloted to licensees, this would provide new channels for potential diversities in broadcasting and minority ownership. However, it will require that changes in the design of AM radio receivers be made. These new receivers should not be more costly than existing ones, although a significant number must obviously be in use for the new allocations to be economically viable.

Proposing that the UHF band be internationally allocated equally among most communications services. Because communications technology is rapidly changing and the demand for local communications is increasing, it is highly desirable to minimize international restraints in this band. Therefore, the FCC is proposing to add the fixed and mobile communications services in nearly the entire band between 470 and 890 MHz which is presently allocated exclusively to broadcasting. This will give the Commission the flexibility to apportion this spectrum among these three services in whatever manner it deems appropriate in future domestic proceedings. This posture does not indicate a lessened committment to domestic UHF broadcasting, but rather a recognition of the great value of the radio spectrum resource, and a desire to make it available for use where appropriate.

Proposing that HF (shortwave) band allocations be adjusted to increase frequencies available to broadcasting, maritime and amateur communications. A number of interests have sought to use the band between 3 and 30 MHz, because of its ability to furnish inexpensive, long-range communications. The Commission has concurred in an NTIA proposal to increase the spectrum available for short-wave broadcasting because of White Bouse interests in increasing the international flow of information, to increase spectrum for maritime communications to accomodate growth in maritime industries, and to increase spectrum for amateur radio to as to accomodate the growing amateur community. With only four broadcasting licensees in the international broadcasting service, the Commission would not appear to have a substantial interest in this matter, and has largely relied on NTIA to reach a compromise among the various affected government agencies.

Proposing to double the available radio/orbital resource available for advanced satellite communication systems at 12 GHz. Because many of our country's technologically advanced, domestic communication systems will be introduced in the 12/14 GHz bands during the next decade, this issue is considered by many to be one of the most significant for the U.S. at the 1979 (WARC). In light of a number of factors, the Commission is proposing to make the entire range of the geostationary orbit available in the Western Hemisphere equally to fixed and broadcasting services; and at the same time, separating into individual 500 MHz segments the frequency bands within which the services must operate.

Proposing amendments which would allow introduction of large-scale, user-oriented satellite systems in a number of bands. Such satellite systems are those which will employ a number of emerging technologies to provide highly efficient, two-way communication capabilities (electronic mail service, voice, facsimile, slow-scan TV) directly to large numbers of very low-cost earth stations. They are systems which can bypass existing terrestrial communications systems to provide interconnection among themselves or with regional information service facilities. From the array of options available, the Commission is proposing that certain allocation and technical specification changes be made to allow appropriate introduction of these satellite systems in the 2.5/6, 10, and 12/14 GHz bands as the technology is developed.

Proposing the protection of certain frequencies for scientific uses. The Commission is proposing the allocation of certain bands, and the application of certain technical limitations, to enable the use of satellite sensing of natural microwave emissions for environmental and weather studies. This technique, known as "passive sensing," allows the determination of things such as the moisture content of the soil, the surface temperature, ice thickness, water vapor, and other data of universal benefit to mankind. Most of the needs of radio astronomy have been met, as have those for the research of the physical characteristics of space.

Proposing an amendment which would allow future consideration of a land mobile-satellite service in the 806-890 MHz band. This amendment allows the implementation of land-mobile satellite service in some 20 MHz segment in the 806-890 MHz band. Such a service could provide inexpensive two-way voice and data communications to a wide variety of local, state, and federal government users in mountainous or rural areas where such systems are not presently feasible.

Proposing allocations to various radio services between 40 and 275 GHz. The present International Table of Allocations ends at 275 GHz. In the spectral region between 40 and 275 GHz, only a few allocations have been made. The Commission said that specific allocations would encourage experimentation and development, and certain bands associated with natural microwave emissions must be protected for the scientific community.

Proposing a number of changes to transmitter technical standards which would improve the efficiency of spectrum use. These changes include additional limits on unwanted signals of radio transmitters, on the requirement that a transmitter stay within a certain frequency range, the eventual conversion to single sideband equipment in the short-wave broadcasting service, and improved control over the pointing of satellite antennas.

The text of the FCC's *Report* and *Order* has been released publicly December 28, 1978. The document consists of 437 pages. Because of the cost of printing so voluminous a text, it will not be published in the FEDERAL REGISTER. However, the FCC has prepared a limited number of copies that are available upon request (*Report* and *Order* FCC 78-849, Docket No. 20271, adopted December 5, 1978, "An Inquiry relative to preparation for a General World Administrative Radio conference of the International Telecommunication Union to consider revision of the International Radio Regulations.") at its Information Office, Room 202, 1919 M Street, N.W., Washington, D.C. 20554. The *Report* and *Order* is also available for inspection at the Commission's Docket Reference Room.

FEDERAL COMMUNICATION COMMISSION.
WILLIAM J. TRICARICO,
Secretary.

STATEMENT OF CHAIRMAN CHARLES D. FERRIS

DECEMBER 6, 1978.

RE: Docket 20271, 1979 (WARC) Proposals.

For over four years the Federal Communications Commission has examined literally hundreds of issues related to the 1979 general World Administrative Radio Conference (WARC). This Conference, which will begin next September, will review the international Radio Regulations and make decisions about use of the airwaves for the next twenty years.

The Commission's proposals will be forwarded to the Department of State which is responsible for forwarding the final U.S. proposals to the ITU. The *Report and Order* represents a careful and in-depth examination of thousands of comments and an expert determination of the future needs of the non-governmental users of the radio spectrum in the United States.

Throughout this process, I have sought, as Chairman, to have the Commission's recommendations reflect several important themes. The first is that our recommendations be based on the public comments of the thousands of interested individuals and groups who petitioned the Commission.

The second is that our proposals provide the United States—and every other nation—with the greatest possible flexibility in deciding how to use the available spectrum. Too often, international and national regulations are inflexible—restricting innovation, *dramaticaly increasing* communication costs, or even precluding development. If the Commission's recommendations are adopted at the Conference, each

editorial by Wayne Green

from page 4

For over twenty years I have been pointing out that the key to the future of amateur radio is a political one. Providing service is great, but it won't buy us anything with politicians. Politics are centered in Washington, and this is why all the other users of radio frequencies have strong organizations in Washington to lobby for their interests. Lacking any such power, amateur radio has been pushed around by the FCC and any other group almost at will. The recent ridiculous 220 MHz grab by the maritime interests should prove this point clearly even to the most iron-headed ARRL supporter. The saving of the 220 band from the CB interests and the EIA had little to do with any ARRL efforts, despite their bragging about it . . . they just don't have any clout in Washington.

An efficient manager of an organization first makes sure that his books balance. This means that income and outgo should be brought together, with income slightly exceeding outgo. That sounds simple, but when you have a fundamental policy of keeping ad rates low to try to make life miserable for other publishers, you have an artificial hold on income. I don't think the chaps who worked out that scheme ever expected someone like me to come along, someone who would start a magazine and not even take any salary for several years, someone to whom the money or lack of it was no serious problem, someone who wanted to provide a magazine to help get hams building at any personal cost.

The first "employees" of *73* were college dropouts who worked more for the fun of it than money, getting $20 a week plus keep. I cooked the meals and we had a ball. Most of them went back to school and we gradually were able to hire local people at more reasonable wages.

To get on a firm financial footing, *QST* should first increase their advertising rates to match those of other magazines with their claimed circulation. Then they should increase their membership fees to a more reasonable rate, comparable to those of other organizations. With the added income, they could set about actually providing some of the services hams think they've been getting, and perhaps providing us with some protection against the FCC, the ITU, and other frequency users.

To give you an idea of how off-base the advertising rates for *QST* are, they claim nearly twice the circulation of *73* and yet have lower advertising rates! How is this possible? And how in the world, under these circumstances, can *73* consistently have more ad pages than *QST*? The answer is simple enough: The ads in *73* pull far better than those in *QST* . . . manufacturers and dealers find the readers of *73* are far more active and buy a lot more ham equipment than *QST* readers.

Part of that situation has to do with the high percentage of older ARRL supporters who get *QST* but obviously don't read it, or at least don't read the ads. They already have their Collins equipment . . . indeed, they've had it for many years, so they look over the articles, note that many of them use transistors, and put the magazine on the shelf. The readers of *73* are a different breed, fed on a barrage of articles on the latest techniques and many simple construction projects. About 90% of the *73* readers are into building to some degree. This explains the many pages of ads for parts . . . a heavier percentage of such advertising than was in *QST* even in the supposed heyday of ham building in the '30s.

QST needs a new crew. They need to come out of the dark ages and fill their magazine with projects which will inspire people to build and enjoy amateur radio. They should cool some of the excessive contest coverage and the endless self-congratulation. They should get their directors to stop being messengers from HQ to the members and get traffic moving the other direction so the official journal of the club can inspire clubs to greater efforts and fun. Do I really have to set up such a section of *73* just to show the League what they should be doing in *QST*?

I'll tell you what . . . let's try it. If your club has a building project, make sure that you have a PR officer whose job it is to document what is happening. Have him write an article for *73*; include good photographs of the item being built, the people who organized the project, and those who participated. Let's run some good solid picture stories in *73* and show what is being done by clubs.

Then there are public service events . . . emergency or otherwise. Have the PR officer take pictures and quickly write up the story, and don't forget good pictures of the people, the important people. I want not only group shots of workers, but also good close-ups of the faces. Let's show who is doing what.

The next time you have a hamfest, picnic, or other group event, try to get a big poster or banner with the club name or call on it and line the whole group up for a mass photograph. Have someone with a good camera take the picture . . . none of your 35mm for this . . . at least 6 x 7 cm . . . black and white, please. If you can get a good color shot, do that, too, but black and white comes first in publishing. It's a whole lot less expensive. Field Day is incomplete without the group photo. Send it quickly to *73* and let's get this going. Please be sure to identify every person in the pictures so our captions will be accurate.

DXpeditions all too often go unheralded. Let's be sure we have someone along on important DXpeditions whose main job is to handle the PR. He must have a camera and take a lot of photos. You've seen the job I did on my trip to Navassa and Jordan. Now, with larger pages to work with and more money for color, we can do even better. Color shots should be taken with good equipment, not with Instamatics.

WOULD IT WORK ?

Instead of people leaving the ARRL like rats from a sinking ship and the rest of the employees living in fear of being fired, the League could meet the world as it is today and do the job that is there to be done. They could easily solve their economic problems, even without selling their million dollars worth of stocks and bonds which they've squirreled away over the years.

Do they really need to put nearly a million dollars into building more offices now that many of them are empty? They don't even have the staff to put out decent books anymore. When we needed more room for people to work in our computer program business, we looked long and hard, finally acquiring a local motel which provides us with room for at least 100 more people to work . . . and at a relatively low cost, less than half what it would cost to build something.

THE ADVISORY COUNCIL

Word was released recently that in a panic over the falling fortunes of the League, the executive committee had formed an ARRL National Advisory Council. Named as honorary chairman was Senator Barry Goldwater. Acting chairman was Buzz Reeves K2GL. Many of the well-known gentlemen announced as council members are millionaires. Council members named were Dave Nurse of Heath, Art Collins, Bill Leonard of CBS, Walt Henry of Henry Radio, Bob Cushman of Cushcraft, Bill Muller of Icom, and John White of Cooper Union. I know most of these men personally and hold them in the highest regard.

Soon after the initial announcement, there was a second one saying that Art Collins had bowed out of the council with the explanation that he felt that "more constructive measures should be found to meet the total needs of the ARRL." I think Art has something there. The problems which have brought the League to this stage of disintegration cannot be solved by passing the hat again for another membership collection. The problems are managerial and are deep rooted.

If there was any simple way to get new management for the League, the directors would have done it long ago. The fact is that once a group gets well entrenched, it is very difficult to blast 'em out.

We'll all be watching to see what powers the Advisory Council has, if any. The word in the title is "advisory," so the assumption is that they have merely the power to advise. I suspect that this limitation may have had a lot to do with Art quitting the group. The men listed are spread all around the country, so it is doubtful if they will be able to get together in a group to tackle the situation. They are certainly as busy as I and won't be able to just drop everything and spend the needed time for an investigation of the many factors which brought on this disaster.

Since the heart of the problem apears to be the little HQ clique running the ARRL, people who for the most part have little background in trying to run an organization of that size and complexity, the committee may have its hands full trying to get cooperation in their investigations. How much help will HQ give to a committee which they see as being organized primarily to bring about their demise?

The gentlemen on the committee are hard-working men,

but they can afford to take on outside projects such as this only as long as they get a lot of cooperation and don't have to spend too much time fighting management. I devote some of my time to working with the local Chamber of Commerce and I enjoy having a hand in governing what is happening in my town. I also spend some time working to make my old submarine crew have a little better yearly reunion. If I can take a bit of time off from running *73, Microcomputing, Microcomputing Industry,* Instant Software, etc., then most businessmen can do the same . . . if it seems worthwhile.

BULLET BITING

The position some of the Advisory Council members are in is not enviable. The needed increase in advertising rates could directly affect their own businesses. The current *QST* ad rates are around $1,500 per page and should, to be consistent with those of other similar magazines, run around $4,500. This would increase the cost of a full-page ad by about $36,000 per year and have to be reflected in higher equipment costs to amateurs. This change alone would bring up ARRL income by about $2.5 million a year and eliminate the necessity for increasing membership fees. It would certainly get the League out of the financial hole the present management has gotten it into.

HOW ABOUT THE IoAR?

Several longtime readers of *73* responded to my December editorial with the question as to why I have not resurrected the Institute of Amateur Radio, particularly in view of the problems with WARC. That deserves an answer.

First, for new amateurs, let me explain what an IoAR is . . . or was. Back in 1963, when *73* was just about three years old, I got the foolish notion of promoting ham-to-ham friendship through a ham tour of Europe. Oh, the idea was good, but the work involved was monstrous. The idea was to get groups of amateurs together and visit amateur groups in Europe.

In order to qualify for a group fare on the airlines, it was necessary to have a formal group. I formed the Institute of Amateur Radio with the primary purpose being the organizing of ham trips to visit DX hams. I advertised the idea in *73* and gathered together a group of 73 for the tour. Odd number.

I made all of the arrangements for airline travel, ground transportation, hotels, etc., including a hamfest in most of the places we would visit. I did all this in addition to editing and publishing the magazine, selling the ads, helping with the subscriptions, etc.

The first place we visited was London. The RSGB (Radio Society of Great Britain) refused to do one damned thing to greet or offer a friendly hand to the 73 visiting U.S. hams and their families. Despite that, a nice dinner was arranged and our group was able to get together with the local amateurs.

The frigid reception from RSGB may have been more of a reaction against the ARRL than U.S. hams in general, since we found the British amateurs to be very willing to put themselves out to show our group around. One of the high points was a visit to the British Science Museum, where the restrictions against third-party traffic had been waived and many of us were permitted to make phone patches back home.

The next stop was Paris and a fantastic reception organized by Pierre Catala F2BO, the local representative of the then quite active Ham Hop Club (a club which organized places for visiting hams to stay with other hams in foreign countries). I'd met Pierre on my first visit to Paris in 1958, so we were old friends by this time. In 1964, Pierre came to the U.S. and worked for *73* as long as Immigration would permit. Then he went to college in New Hampshire and graduated from the University of New Hampshire. He's now in Haiti working for the ITU.

The French amateurs pulled out all the stops and we had a beautiful visit to Paris. We all got together for a big hamfest and most of the group had French homes to visit.

The next stop was Geneva, where an international hamfest had been organized by the ITU hams. There we had a dinner with hundreds of hams from all over Europe who had come in for the occasion. Just about everyone got to operate 4U1ITU and we all had a ball.

From Geneva, we flew to Rome, where we had an audience with the Pope. From Rome, we flew to Berlin and another great hamfest-dinner, getting together with just about every active Berlin ham. We arranged bus tours of the east and west sections of the city, and it was a memorable visit.

How much did I charge for all this? The complete price for the trip, including round-trip airfare, ground transportation, hotels, all breakfasts, tours of some cities, and a hamfest in most cities with dinner, came to $550 per person. Not bad for a three-week trip to five major cities. The regular tourist round-trip fare to Rome alone was $625 at that time.

Everyone had a fantastic time. I still meet people at hamfests and conventions who were on the trip and say they wish we could do it again. It was a memory all of us will carry with us.

At $550, we obviously didn't make any money, But then, despite the claims of my critics, money has never been anything more to me than a way to get things done, so I have tended to just scrape by.

The tour was in October, 1963, just at the time that the League petitioned the FCC for what they amusingly called "incentive licensing." This beaut, for those of you who were not there, called for throwing most of us off the phone bands we had been using and forcing us to take a new license exam to get back our previous privileges. It went over like a lead balloon. Sales of ham equipment dropped from $35 million in 1963 to under $5 million in 1965, largely in response to this fiasco. Ham growth stopped in its tracks, not going into the plus column for over ten years after this bomb.

The reaction of many hams was to look desperately elsewhere for some organized support. Suddenly my little travel club was being pushed to become a national organization. The $1 membership fee was increased to $10 and the IoAR was up and running. The purposes of the Institute were to do the things which the ARRL could not or would not do, such as lobby in Washington, furnish cash for hams fighting legal battles which could affect us all, etc. It was set up so as not to challenge the ARRL in any of the activities it was actually doing.

This is not the place to cite all of the dirty tricks the ARRL cooked up to try to scuttle the Institute. Several ARRL directors bragged to me that the League would spend *any* amount of money to shoot down the Institute and it didn't take long before I realized that this was a fact. Directors rushed around to every club in their divisions denouncing any

Corrections

Two errors exist in "Light Up Your Life" (December, 1978). First, the PC board layout (Fig. 2) should be replaced with the one shown here. The original Fig. 2 shows, incorrectly, the component side, rather than the foil side. Second, the pin numbering scheme for the 5th digit readout (Fig. 1) contains *two* pin 11s. The *lower* pin 11 should be labeled 7.

We regret the trouble that these errors may have caused.

Gene Smarte WB6TOV
News Editor

Since the time that I wrote the article for the WR7AEK battery charger, Tri-Tek has stopped advertising in *73*. Please print their address as follows: Tri-Tek, Inc., 7808 N. 27th Ave., Phoenix AZ 85021, 995-9352. Please send your money to them and not to me. Specify you want the "WR7AEK battery-charger kit," not "the thing by WA7DPX in *73 Magazine*." For Mr. R. B. Hintenoch and others who have written (or called)—no SASE, no answer. I have enough bills without making the post office rich. Thanks to those who have written letters to me about the article.

James Wyma WA7DPX

ham supporting the Institute as a traitor to amateur radio. A newsletter began being sent to clubs everywhere and to every member of the Institute (I published their calls) telling them, month after month, that I was a crook, that everyone involved with the Institute was a crook, that I was going to kill amateur radio, etc. Dick Cowan dutifully helped with some similar comments in *CQ*.

In the midst of this increasing war, I got involved with a really miserable divorce. Unless you've been through something like that, you don't know what it is. It stopped me more than anything else for quite some time. I realized this and got together with the board of directors of the Institute and insisted that they find someone else to act as secretary for the organization until I could get back into better working shape.

The board tried hard to find someone to work for the same price I did . . . nothing. They finally settled on Dave Middelton W7ZC, who would do the work but insisted on a very nice salary for his time, even though he was retired. This resulted in the funds which I had built up for the Institute being spent for his salary and little else, finally running out completely. My main expenses had been for publishing and mailing newsletters to Congress telling them about the good things radio amateurs had been doing . . . such as helping get medicine to remote parts of the world and the amateur radio service during the Alaska earthquake.

By the time I had managed to get back into some sort of good working shape, the Institute had collapsed from the attacks of the ARRL and the internal bleeding by the secretary. I decided to sign up again as secretary, but instead of soliciting members, I decided to do the needed work myself. It was more trouble to get memberships, fight off the ARRL, send out membership cards, etc., than to spend the needed PR money out of my own pocket to get the job done.

MORE HAM TOURS?

With the 1963 trip such a success, I wanted to do more of this ham-to-ham friendship activity. I announced another ham tour of Europe in *73* for 1965 and waited for the deluge of people to sign up. The first trip had been so much fun for everyone involved that I felt we would have an even better trip the second time. Imagine my surprise when, on looking closely at the list of those signed up, I found that virtually all of the people were repeaters from the first trip. It was then that I realized that there was a very limited number of hams with $550 and the time for such a trip. I called it off.

We did try it again in 1968 and had a very nice tour of Europe, visiting Madrid, Amsterdam, Paris, Copenhagen, etc., but the smaller crowd involved confirmed again that the number of hams able to participate in such a tour is very limited. Hams are, for the most part, middle and lower-middle income people, and not many can afford the luxury of a three-week vacation in Europe with the XYL. Better to put the money into a new rig, I suppose.

WHITHER THE INSTITUTE?

In view of the present growing disenchantment with the League over their bumbling of the WARC planning and other recent problems, is there a need for a second national amateur organization? Right now I don't see any serious need for one. There is no question that with the usual 20-20 hindsight, we can see that we sure should have had one last year to get the WARC situation covered in Africa.

If we do manage to come through WARC with enough ham bands to survive as a hobby, then we will definitely need a second national ham society. The key to the whole situation facing us is a political one, and this means that if we are going to cope with the government, the FCC, the ITU, etc., we must have a strong lobby in Washington. That's where the power is, and that's where we need to be covered.

A good lobby can not only put pressures on the FCC to prevent gross miscarriages of justice like the recent linear amplifier ban and the 220 MHz maneuvering by CB and the maritime interests, but it could also help us get things through Congress and put pressure on other government agencies to support amateur radio, which we need desperately at WARC.

At the last WARC, where I was one of the two active ham delegates, I found that this lack of clout in Washington had resulted in amateur radio having little more than lip support by even the U.S. delegation. Despite the official U.S. position that amateur radio would be supported 100%, the private instructions of the delegates from their organizations were that if their service lost any frequencies, they were to be replaced by frequencies taken from the nearest ham band. Our allocations were considered a sort of emergency supply source for frequencies. The delegates pointed out that this was purely a political matter that the service with the least clout was bound to be the loser. Just about every other user of radio frequencies maintains a strong lobby in Washington, so they come first.

NOVICES ON 220?

The Canadians are all upset over an ARRL proposal to open the 220 MHz ham bands to Novices. Frankly, if I already didn't have a petition on file with the FCC for this band to be opened for Communicator use, I'd probably get upset, too. Not very much, though.

The ARRL has, in the past, endorsed the Communicator idea for 220 and not a few of the major manufacturers are quite convinced that such a new class of license is inevitable . . . and soon. For my part, I think I could get up in front of a large group of amateurs and argue effectively either for or against a Communicator license. There are many benefits to be derived from such a plan . . . and there are many drawbacks.

I filed the original petition so long ago that I forget just when it was . . . about ten years ago, I think. My scheme in filing it was to present a viable alternative to taking the band away for CB use and hopefully to divide the manufacturers enough so that CBers wouldn't take our band. I figured that if the Communicator Class license actually did go through, it would have more benefits than drawbacks, although I felt that the two proposals might just defeat each other with the result that there would be no major change in 220.

The League surprised me with a historic first . . . they supported the Wayne Green petition. They really had little other choice. With the CB manufacturers pushing hard through the EIA (Electronic Industries Association), the ARRL *had* to come out with a positive move. To just try to hold the status quo was far too weak an argument and would obviously lose the 220 MHz band for amateurs. To come out with a third proposal would split the ranks too much for success . . . so they had to support my proposal, much as they hated the idea. I had a good laugh with several of the directors over this.

As a passing matter and off the point, I am on good terms with some of the ARRL directors and hold a few of them in great respect. I'm not personally at war with anyone at the ARRL and hold no personal grievances. I'm neither in awe of nor afraid of the men running the show. They don't seem to feel the same about me, so we do have difficulty in getting together. That's a pity, for I've found that even the widest differences can usually be overcome if people will sit down and discuss things. This presumes that those participating are honestly motivated.

At any rate, now that the 220 threat to CB has finally been laid to rest, I think the ARRL wanted to put a stop to the proposed Communicator Class license and felt that the safest way to do this, while still appearing to support the manufacturers, was to put in a counterproposal. This would in all probability stall things for a few more years and permit the whole matter to eventually be washed away.

I see no real point in taking up any argument for or against releasing tens of thousands of Novices on 220 MHz since I don't think the ARRL is serious about it.

ST. LOUIS, MARCH 31

Mark off March 31 on your calendar and plan to come to St. Louis for one of the most fun hamfests yet. It'll be worth the trip. I'll be there to talk about hamming and also about microcomputers and answer any questions you have. Sessions like this are great because there are a lot of things that I can tell you in person that I wouldn't dare to write.

What started out as a simple visit by Wayne Green to St. Louis has been escalated into a full-fledged hamfest. It will be at the H. J. Cervantes Convention Center and there will be forums on many aspects of amateur radio all through the day. Planned are sessions on OSCAR-AMSAT, repeaters, RTTY, 10/10 International, YLRL International, SWOT, linear amplifiers, DX with Father Moran 9N1MM from Nepal, SSTV by Robot, antennas by Hy-Gain, and some special sessions for the XYLs, etc.

Exhibits? You bet. So far the following are signed up or expected: Yaesu, Kenwood, Robot, VHF Engineering, Hy-Gain, MFJ, HAL, ETO, Kantronics, Ham Radio Center, Henry Radio, Cushcraft, Tennalab, Sinclair, Telrex, Rohn, Southwest Technical Products, CB Products, Ten-Tec, DSI, Info Tech, Microlog, Radio Shack, Drake, DenTron, Icom . . . and there will be a lot more. Dealers will be coming with some fantastic special prices.

Just to get the show off to a good start, I'll be in a day ahead and will be on the radio and television stations through a good deal of Friday drumming up interest in the hamfest for Saturday.

The event is going to be called "ARCH MARCH" . . . ARCH for the famous St. Louis Arch and MARCH for Midwest Amateur Radio and Computer Hobbyists. The show will be put

on by an amalgamation of 22 clubs in the area, led by Bob Heil K9EID.

The idea for the hamfest grew out of a phone call to me from Bob Heil. He wanted to get me out to talk to the Marissa Amateur Radio Club (Marissa, Illinois). The more we talked, the bigger it grew. On December 15, Bob met with representatives of nine area ham clubs and the show was on the road.

There has been a need for a hamfest in the St. Louis area and I'm delighted to see this shaping up so quickly and so well. The idea is to make this a yearly event. If you can possibly make it to the hamfest, please come and help make this a winner. Bring all the hams that you can.

Since, as far as I know, I'm not on the program to speak at either Dayton or Atlanta, this may be the *only* place where you will have an opportunity to find out what is really going on . . . and to ask the questions you wish you could get answered.

SWISS REPEATER

They may not have as many repeaters in Europe as we do, but you can't fault them on innovations. A Swiss repeater has a very sophisticated receiving system . . . it uses a microprocessor to check the direction from which a received signal is coming and switches the receiving antenna to that bearing from an omnidirectional pattern. It can also be used to check the location of the station and compare that with the callsign. Does that give you repeater owners any ideas? The Swiss repeater is so effective that it is able to cover virtually all of France.

HELP YOUR LIBRARY

Presumably you enjoy *73 Magazine* and realize that if more hams would read it, they would get a lot more enjoyment out of amateur radio. The articles are also top-notch for getting newcomers fired up with an interest in amateur radio. You can help enrich some lives by making sure that *73* is in your local library. Oh, it won't cost you anything except the time to check and ask.

If you find that it is not in your library, please make sure that the head librarian knows that you think it should be there. You might point out that *73* is the largest of the ham magazines and has more articles than any other . . . indeed, more than all the others combined some months! *73* is more of an ongoing encyclopedia of amateur radio than just a ham magazine.

In most cases, by the time two or three people have asked that *73* be in your local library, and they know where to write, we'll be getting a purchase order from them. And what school library is adequate without this reference? Let's see what you can do.

NOVEMBER WINNER

Dr. Ralph E. Taggart WB8DQT will be receiving our $100 bonus check for the November issue's most popular article, "Be A Weather Genius." Keep those Reader Service card ballots coming in!

COINCIDENCE

During the recent Aspen ham industry conference, we had quite a group sitting around a table at one of the nicest restaurants in town. I had just handed out some brochures by a ham advertising agency promoting the use of a ham-run ad agency for advertising and marketing when the waiter asked if I was a ham. I said sure, and he asked my call letters. Just to be smart, I turned my belt buckle with my call engraved on it up and looked at it . . . and read off W2NSD/1. The waiter gave a laugh and introduced himself as Fred WB0FOR, and said that he was the one who had made the belt buckle for me.

I'd tried to get in touch with him the year before, but he'd been away during our conference. Colorado Silver, located in Aspen, had been advertising in *73* and turning out extraordinarily good belt buckles for hams who are proud of their calls. The buckles come in bronze for $13.50 and have to be one of the nicer gifts a wife can give a ham. I wear mine a lot and it gets noticed. I remember once in Berne, Switzerland, when a woman saw it and said that her son was a ham . . . etc. For a bit extra they are available in solid silver. You can look up their ads during 1978 in the April and June issues.

New Products

from page 19

ged, compact unit which fits easily into the palm of the hand, the LX 303 features a large, ½-inch, angle-mounted LCD readout for high readability indoors and out, even in bright sunlight. A reading rate of 3 readings per second makes accurate reading fast and convenient. Battery life is 200 hours minimum (300 hours typical) from a single 9-V alkaline battery. Handy battery check capability is also provided.

Ruggedness is achieved in the LX 303 by combination of light weight (12 oz., including battery), compact size, a high-impact thermo-plastic case, and glass-epoxy PC board construction. Ruggedness is further enhanced by a snap-on cover which protects the entire front panel during storage or transmit, whether in a briefcase, toolbox, or storage bin. The snap-on cover can also be used to store the test lead set included to effect a totally self-contained, protected instrument. All input jacks are recessed for operator safety.

Reliability is assured by the use of LSI circuitry and laser-trimmed thin-film resistor networks for low parts count. The excellent overload characteristics provide 1000-volt protection on all dc voltage ranges except the 200 mV range (which is protected to 500 V). All ac ranges are protected to 600 V. All Ohms ranges are protected to 120 V. Maintainability is also excellent, due to the use of sockets for the major components (including the display) and the extensive use of standard components. The unit is covered by a 1-year warranty.

A full complement of accessories is also available, including an ac adapter (115 V ac and 220 V ac versions), a padded vinyl carrying case, a 10-A dc current shunt, a x10 dc V probe adapter which protects the input to 10 kV, and a x100 40-kV dc probe. For further information, contact *The Hickok Electrical Instrument Company, 10514 DuPont Ave., Cleveland OH 44108; (216)-541-8060.* Reader Service number H35.

PALM-SIZE CSC MAX-550 MHZ COUNTER

The newest and most capable frequency counter in the "Max" line from CSC is the MAX-550, a new, palm-size frequency counter which boasts a 1-kHz-to-550-MHz range. This counter is no bigger than most pocket calculators.

The counter's 50-Ohm input (via a BNC connector) has a sensitivity in the milliwatt range. Its 6-digit LED display features 1-kHz resolution. Any of several sources of 7-12 V dc can be connected through the counter's coaxial power connector. And a number of accessories—including cables, a case, alternate power sources, and so on—will be offered.

Additional information is available from *Continental Specialties Corporation, 70*

CSC's MAX-550.

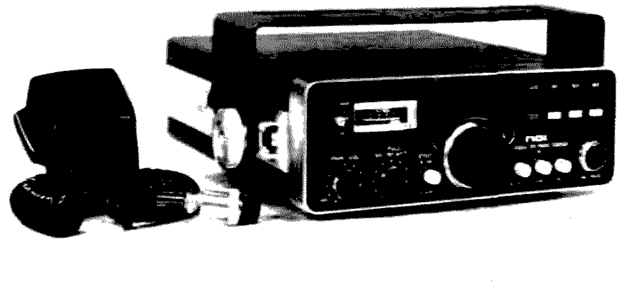
NDI ANNOUNCES 800-CHANNEL 2 METER TRANSCEIVER

NDI, Inc., has announced the HC-1400, a new high-performance 2 meter FM mobile transceiver. This microprocessor-controlled, digitally-synthesized unit has 800-channel capability within the amateur 144-148 MHz band, and offers 5- or 10-kHz channel spacing. A fast-acting single knob selector shifts LED digital frequency readout in 10-kHz steps, and the rig also has a 100-kHz "speed-up" button. Transmit offsets are preprogrammed and switchable to plus or minus 600 kHz. Simplex operation is also available. This set can be programmed to hold three Tx-Rx pairs in memory, and has capability for instant recall. The receiver uses an FET front end with three coax resonators, a crystal lattice filter and multi-tuned circuits in a dual i-f. The FM transmitter delivers 25 W output at 13.8 V dc. Power is reducible to 5 W. Size: 7.1" W x 2.6" H x 10.1" D. A mounting bracket and a detachable microphone are also supplied. For further information, contact *NDI, 22125½ South Vermont, Torrance CA 90502; (212)-320-3312.* Reader Service number N19.



The HC-1400, NDI's new 2m transceiver.

TEMPO 800-CHANNEL HAND-HELD TRANSCEIVER

The amazing pocket-sized Tempo S1 SYNCOM offers the first fully-synthesized 800-channel 2 meter miniature amateur hand-held transceiver. Other units which are larger, heavier, and similarly priced (by the time you add crystals, batteries, chargers, and antennas) can offer only 6 channels. The S1's price of $349 *includes* the battery pack, charger, telescoping antenna—and 800 channels!

Top-panel thumbwheels allow selection of the receive frequency to 10 kHz. The +5-kHz slide switch offsets to 5 kHz if desired. Then you have the choice of transmitting simplex, +600 kHz, or −600 kHz.

The S1's separate speaker and microphone are both built-in. Rf output is better than 1.5 Watts nominal. A matching 30-Watt output amplifier is available for mobile or fixed operation. The dual-conversion receiver section has a sensitivity of better than 0.5 microvolts nominal for 20 dB of quieting, and spurious and harmonic attenuation is 60 dB nominal below the carrier power level. Measuring 2.5" wide x 6.5" long x 1.6" deep, the unit weighs 16 ounces with batteries.

The Tempo S1T is the S1 with a factory-installed 12-button touchtone™ pad ($399). Accessories for the S1 and S1T include the TS-CC heavy leather holster with snapped belt loop ($16), the S30 matching 30-Watt amplifier ($89), the TS-MC cigarette-lighter-plug mobile charger ($6), the TS-HA rubber-coated flexible antenna ($8), and a full line of tone accessories, all types of touchtone pads, many different amplifiers, and power supplies.

The Tempo S1 and S1T and accessories are available from dealers throughout the US and all over the world. *Henry Radio, 11240 West Olympic Boulevard, Los Angeles CA 90064; (213)-477-6701.* Reader Service number H3.

HUSTLER INTRODUCES NEW 2 METER MAGNETIC-MOUNT ANTENNAS

The new Hustler Model BBLM-144A 2 meter magnetic-mount antenna was recently announced by New-Tronics. The base-loaded 52" antenna offers a unique magnetic-mount design with much stronger grip per square inch of magnetic surface than is normally available in magnetic mounts.

Careful design of the shunt-fed matching system guarantees maximum signal radiation at the point of lowest swr. The tapered stainless steel radiator provides maximum protection against flutter and detuning at freeway speeds. The power capacity exceeds 200 Watts. The BBLM-144A includes 17' of top-quality RG-58 coaxial cable with factory-installed connectors.

The SFM 2 meter mobile antenna with magnetic mount also inlcudes 17' of RG-58 coaxial cable with factory-installed connectors. The 54" tapered whip is ground of 17-7 PH stainless steel. A bandwidth of 6 MHz and better than 2:1 vswr can be expected. The power capacity is 100 Watts.

For further information, contact: Sales Department, *New-Tronics Corporation, 15800 Commerce Park Drive, Brookpark OH 44142.* Reader Service number N2.

NEW BEARCAT® THIN SCAN™ IS WORLD'S SMALLEST SCANNER RADIO

The new Bearcat® Thin Scan™.

A new portable scanner radio, just 2¾ inches wide and 1 inch thick, has been introduced by Electra Company. Named the "Bearcat Thin Scan," it is described by Electra as the "world's smallest scanner radio." Because of its exceptionally small size and light 10-ounce weight, the radio is a truly practical pocket portable unit. Featuring a rugged all-metal case with a polished, anodized aluminum front cover, the radio is expected to be especially popular with professionals and others who require a scanner in demanding on-the-go situations.

The new Bearcat Thin Scan has 4 channels and receives both "low band" (36-44 MHz) and "high band" (152-164 MHz) with excellent 0.6-microvolt sensitivity. Each channel is provided with a lockout control for bypassing when desired. The radio can be operated from external power as well as internal batteries. Also contributing to the radio's versatility are provisions for plugging in an external battery charger, headphone, and external speaker. A flexible "rubber ducky" antenna is supplied, but the radio can also be used with wire antennas.

For further information, contact *Electra Company, PO Box 29243, Cumberland IN 46229.* Reader Service number E40.

YAESU'S FT-7

I've owned my FT-7 low-power mobile rig for a year now and have really enjoyed it. I bought it on Okinawa while with the US Navy, so I have the Japanese version instead of the US one. The main difference is the language of the manual.

The FT-7 covers 500 kHz of the 80-15m amateur bands, plus one 500-kHz portion of ten meters (28.5 to 29.0 MHz). The FT-7 operates on USB, LSB, and CW, with a choice of vfo, RIT, or fixed channel operation. The rear panel has provisions for a standard SO-239 rf connector, a ground post with butterfly nut, subminiature jacks for key and external speaker, a six-prong plug for power, and a multi-pin jack for an external vfo (although they don't make a vfo specifically for this radio).

The FT-7 input power is 20 Watts dc. The receiver is rated at .5 uV sensitivity for a 20-dB S/N ratio. It has an audio bandwidth of 2.4 kHz − 6 dB and 4.0 kHz − 60 dB. The audio output is 3 Watts with 10% THD into 4 Ohms. The FT-7 requires .4 Amps on receive and 3 Amps on transmit of 13.8 V dc. It measures 9" W x 3" H x 12" D.

The FT-7 came well-packed and included a hand mike, 3 subminiature connectors, a fused power cable, an rf connector, a phone-plug-to-subminiature-connector adapter, and a mobile mounting bracket.

My personal impressions are very favorable. The audio is clear and crisp, and the styling is smart and functional. I've had no trouble working the world with just the FT-7 and a trap vertical. My only two complaints are the lack of a CW filter and the inconvenience of only having one ten meter position on the radio. Overall, it is a very nice radio.

Yaesu will soon be coming

out with the FT-7B, which is basically the same radio with the addition of all of the ten meter band and with the power having been raised to 50 Watts input. Reader Service number Y1.

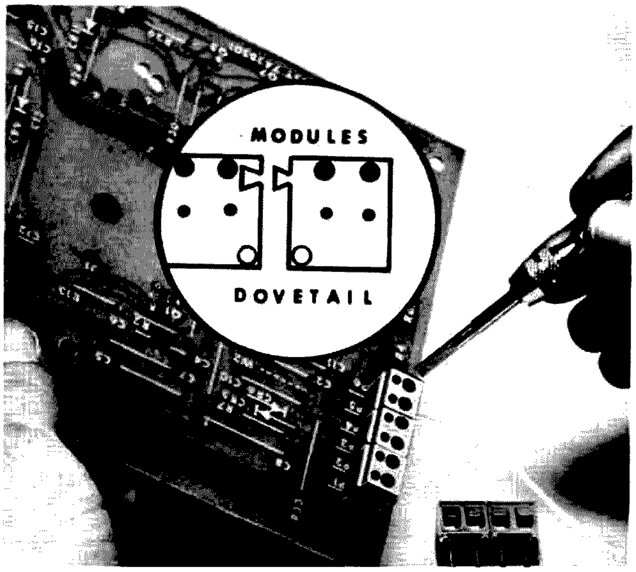
MODULAR TERMINAL STRIPS

TS-6MD terminal strips are 2-position modules which are end-stackable via interlocking dovetails to create strips of any desired length. Each module consists of two screw terminals on .200-inch (5.08mm) centers, each terminated with a .197-inch (5mm) long x .039-inch (1mm) diameter pin for easy soldering to the PC board. Screw terminals feature corrosion-protected tubular clamp contacts and captive, self-locking, vibration-proof screws for secure clamping of solid or stranded wires 16-26 AWG without solder. Bodies are molded of durable high-dielectric nylon and are unaffected by severe environments. Electrical rating is 5 Amps at a nominal 50 V dc. TS-6MD are available from stock at your local electronics store or directly from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.* Reader Service number O5.

WIRE-WRAPPING KIT

OK's new wire-wrapping kit features selected items of particular value to the prototype engineer and hobbyist alike. It includes a unique new wire-wrapping tool, a roll of wire-wrapping wire, and pre-stripped wire in 4 popular lengths.

The tool, Model WSU-30, is a combination one which wraps *and* unwraps 30 AWG wire on .025" square pins, plus strips 30 AWG wire using a handy built-in stripper. The wire is top-quality, Kynar-insulated, silver-plated copper. Supplied in the kit are a 50-foot roll, as well as pre-cut and stripped wire in insulated lengths from 1-4 inches, stripped 1 inch on each end. Available with blue wire as Model WK-2B, white wire as WK-2W, yellow wire as WK-2Y, and red wire as WK-2R, the kit can be purchased from your local electronics dealer or directly from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.* Reader Service number O5.



OK's TS-6MD modulator terminal strips.

NEW HUSTLER FIVE-BAND TRAP VERTICAL FIXED STATION ANTENNA

Hustler recently introduced the new Model 5-BTV, a five-band trap fixed station antenna. The unit covers 10, 15, 20, 40, and 80 meters (tuneable to 75 meters). The 5-BTV consists of the popular Hustler Model 4-BTV and RM-80-S resonator and spider assembly.

In restricted or unlimited space locations, the Hustler 5-BTV delivers top signal performance, consistent contacts, five-band operation, and complete coverage. Switching or matching devices are not required.

The total antenna length is 25'5". It is constructed of the finest-quality heat-treated seamless aluminum and all-stainless-steel hardware. The antenna mounts to any 1¾"-o.d. vertical support. Vswr is better than 1.6:1 at all band edges. The power capability is the full limit on SSB and CW.

For further information, contact: Sales Department, *New-Tronics Corporation, 15800 Commerce Park Drive, Brookpark OH 44142.* Reader Service number N2.

DX

from page 12

and Industry, Government of the British Virgin Islands, Tortola, British Virgin Islands, B.W.I.

Mr. Swain doesn't say if the license will be mailed to you or you must pick it up. Apply early just in case and bon voyage.

NOVICE CORNER

Some have written to complain about the name of this section. The term "novice" doesn't necessarily apply only to Novice license holders. It just means one who is inexperienced. You may be an old-timer with an original two-letter call and still be a novice when it comes to DX. This part of the column receives more comment than any other, but with more than 100,000 new licenses issued since 1975, I guess there really are a lot of newcomers active on the DX bands today.

A few weeks ago, I was calling a C5 station when someone called me and asked where the C5 was located. He needed to know so he would know in which direction to point his beam.

If you really intend to be a serious DXer, one of the first things you need to learn is the different prefixes used by each country and where these countries are located. Any DXer worth his bandwidth should be able, when he hears a station, to instantly know what country is calling and where that country is located. I realize that with over 300 countries on the DXCC countries list, that seems like a formidable task, but it really isn't that hard and it comes naturally with experience.

You should always have within fingertip reach at the operating position a copy of the ARRL DXCC countries list, a world atlas, and a Great Circle beam direction chart centered on your QTH.

The DXCC countries list can be obtained by writing to the ARRL and requesting a copy of Operating Aid #7. If you use an ARRL logbook, then you can use the countries list in the back of the logbook. Every time you hear a call that you don't recognize, look it up in the countries list and try to remember where it is from. Also, study the calls of the countries you need so when you hear one, you'll immediately recognize where it is.

If you're not sure where a country is located, look it up in a world atlas. It's always interesting to locate the various countries on a map. You can see what countries they border and find other information on a map. The people that publish the *Callbook* also publish a very good world atlas showing the call letter prefixes, zones, continents, etc., of every country in the world.

A Great Circle beam direction chart centered on your QTH will show you the exact direction to point your antenna in order to work any country on the DXCC countries list. Order one from Interproducts, 2377 Pollard Ct., Los Gatos CA 95030.

With these tools to work with and a little practice and experience, you should soon be able to recognize any call you hear on the bands and know exactly which direction to point your beam for maximum signal strength.

HEARD ON THE BAND

Due to a problem with the local MARS station and a desire to relax for awhile, WA4YVG/VQ9 on Diego Garcia has gone QRT. QSL to 102 Schoolfield Drive, Danville VA 24541.

That EU prefix being heard is White Russia. Replace it with UC and you have the correct call.

YI1BGD's signal has definitely improved. Word has it that the FT-560 supplied by the NCDXF is now on line.

A9Z was a special prefix to mark National Day in Bahrein.

Bhutan has begun a program of training wireless operators in the hopes of becoming self-sufficient in that area. It is hoped that some of these will become hams.

ZS6DN has a two meter beacon on 144.13 MHz. He would like reports from anyone hearing it.

In the Pacific area, the Gilberts go independent in July and will thereafter be known as Kiribati.

If you are looking for some old XW8 QSLs, this might help. XW8FN is Lloyd Gruhn, 1640 South Parfet Court, Lakewood CO. XW8AL is now FØDAJ. XW8LA is now in Pakistan and can be reached at the U.S. State Department. W3HNK is reported to have the old XW8FN logs.

VP8PL left South Georgia in January.

Beata Island, off the southern coast of the Dominican Republic. This island is the site of the HI1RCD DXpedition.

Some JAs are looking at an island a few hundred miles from Okino Torishima which they feel would be a new one because it is under separate administration.

That HDØE heard during the CQ WW Contest was from the Kingdom of Chaullabamba Nudist Camp. A special QSL is available that should rekindle your interest in QSL card collecting. QSL to WA8TDY/K9LJG with usual SASE.

FY7BC was on from Devil's Island. Ron plans to submit documents to the DXCC desk showing that Devil's Island is administered from France and should be considered as a separate country.

DX NOTEBOOK

Aves Island YVØ

A big operation by K1MM, YV5DFI, YV5ANF, and YS1RRD is being planned for the March/April period. Initial thinking calls for three stations and an allband around-the-clock operation.

Malpelo HKØ

Early plans are being made by the Colombian Radio Club for a 1980 effort. Plan ahead.

Jan Mayen

LA7JO keeps the following skeds with JX4GN and JX9WT: each Wednesday/Thursday at 1700Z on 14270 or 14240 kHz, same time Saturday on 14270 kHz, earlier at 1100Z on 28570 kHz, 0900Z on 14270, Sunday at 1400Z on 28570 kHz.

Navassa

The recent Navassa operation was a huge success with over 22,000 QSOs. SSB accounted for 62% of the total and the special push toward Asia netted 902 JA contacts. Thirty-three OSCAR contacts were made and one six meter contact.

Thanks to the *West Coast DX Bulletin*, the LIDXA newsletter, and *WorldRadio Magazine* for much of the preceding information.

WCDXB NEEDED COUNTRIES LIST

Although several "Most Needed" lists have appeared in the past, the list in Table 1 compiled by W1AM from the personal lists of over 900 subscribers worldwide to the *West Coast DX Bulletin* is the most extensive and complete. The poll was based on the 150 top countries from the 1977 list plus additions of a few new countries which have come on the scene in the past year. The list as printed in Table 1 represents the overall U.S. need on a mixed mode basis. The entire list runs to 153 countries, but we have included only the top 25.

The biggest loser was Clipperton, which dropped from #4 last year all the way down to #152 this year. The biggest gainer was FW8-Wallis Island, which jumped from #126 to #67. This should give you a clue as to where to plan your next DXpedition.

1978 Rank	Country	% need	1977 Rank
1	3Y Bouvet	85	2
2	BY China	84	6
3	8Z Neutral Zone	82	5
4	VS9K Kamaran	81	7
5	XZ Burma	78	8
6	ZA Albania	76	9
7	1S Spratly	76	12
8	VKØ Heard	75	11
9	Laccadives	72	14

Ham Help

I have been an avid reader of your magazine since 1973, when I discovered it on a newsstand at the PX at Ft. Jackson SC. I have been in the Air Force fourteen years as an electronics technician. Now I am stationed in Germany and am so tired of waiting for Stars & Stripes bookstores to stock your latest issues every month that I just gotta subscribe! You put out the best magazine I have seen.

I have been poring over all the back issues of every electronics magazine I have and have not found a good general-coverage receiver project anywhere. I sure would like to build my own from scratch! It would be nice if it was PLL circuitry, covered 0.5 to 50 MHz AM, CW, and SSB, with possible provisions for the later addition of either Hi or Lo VHF/UHF scanner or FM band converters. If it is the latest technology, it should include digital readout and possibly a clock! Power requirements should be 120/240 V ac and 12 V dc.

Well, got anyone working on such a gizmo for possible future inclusion in *73 Magazine*?

Patrick T. Berry
Box 222
APO NY 09692

Corrections

In "Time-Domain Reflectometry," January, 1979, Fig. 6 shows a 74S104, which is not only difficult to find, but also incorrect. The correct IC should be a 74S140.

Gene Smarte WB6TOV
News Editor

RTTY Loop

from page 24

Fig. 4(b). This prevents the chip from sourcing current and looks like the open collector at the expense of a 1N914. If you need a circuit that keys "upside down," then use the 7406, shown in Fig. 4(c). In fact, by using two inverters and feeding one or both, a normal/reverse mode can be implemented.

To get this single character stunt box working, hook up the clock, UART, and buffer chip of your choice as shown in the diagrams. Again, be sure to provide a negative twelve-volt supply for the UART in addition to the normal TTL 5 volts. If you have a frequency counter, set the clock to 727 Hz. If not, program in an R and use your TTY machine to tell you when you've got the right speed. The table from last month can be used to program in any letter or character you desire.

I'll give you all a month to play with this one. Next month we'll hook up the matrix to give a real purpose to all this dilly-dallying. A look into the crystal (FT-243 style) ball shows some more programming in store for you computer buffs. A full transmitting program, with buffers and a true FIFO, is under way for the 6800. Watch for it in RTTY Loop.

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

from page 168

national administration will be able to choose how to best meet its national communications needs. This flexibility will aid the less developed nations, as well as the U.S., in communications planning, and will facilitate the development of innovative services which may radically restructure the way we communicate as we approach the 21st Century. For example, new uses for communications satellites, new systems for electronic message distribution, should benefit from this flexibility.

A third principle underlying the Commission recommendations is that detailed analyses of the policy choices in communications planning are required. Even given the flexibility of U.S. proposals, the available spectrum is simply insufficient to meet all possible communications needs. Our recommendations make clear our policy choices.

A fourth and related principle is that every effort must be made to conserve the spectrum. The spectrum is one of our most valuable resources. Recommendations that encourage inefficient use of the spectrum will only lessen our ability to communicate—a precious ability in an interdependent world such as our own. As technology develops we must be able to utilize it to increase spectrum efficiency.

Finally the Commission's recommendations seek to provide our country with increased diversity in the electronic media. Adoption of the Commission's expansion in the AM broadcast band could provide hundreds of new stations which would allow those who have traditionally been excluded from our electronic media to enter into the communications mainstream. In another example, the adoption of our recommendations would preserve the possibility of direct broadcast satellites providing new channels across the United States.

The Commission's formal work is over with the adoption of this *Report and Order*. I look forward to following the proceedings of the 1979 Conference with great interest. Because of its fundamental importance, I hope all concerned citizens will also be watching.

JOINT SEPARATE STATEMENT OF COMMISSIONER ABBOTT WASHBURN AND COMMISSIONER JAMES H. QUELLO

DECEMBER 5, 1978.

RE: Docket 20271, WARC 1979 Proposals.

President Carter has enunicated a policy of increasing the international flow of information and, for this purpose, has adopted a policy of increasing the use by the United States of international shortwave broadcasting * * * primarily by the *Voice of America, Radio Free Europe,* and *Radio Liberty*. The frequency allocations for international broadcasting contained in today's Report and Order—totaling an increase of 865 kHz—reflect but one alternative now under active consideration within the Executive Branch of the Government. This total falls some 800 kHz short of the proposals that have been made by the International Communications Agency and the Board by International Broadcasting.

Inclusion here of the 865-kHz alternative was not based on any independent analysis by the Commission. The FCC has merely deferred judgment in this matter to other agencies of the Executive Branch.

In the interest of accuracy, we believe it should be brought to the attention of all interested parties, here and abroad, that at the time of the Commission's action (December 5, 1978) there has yet been no decision within the Executive Branch as to a final figure for a U.S.-proposed frequency allocation for international broadcasting.

This is the purpose of our joint separate statement.

Ham Help

I need assistance in setting up a Kenwood TS-520S and HAL ST-5 for RTTY.

Charles E. Martin AB4Y
PO Box 3370
Bowling Green NY 42101

I would like to obtain information and/or manuals for the following pieces of gear: RT-159/URC-4 military surplus hand-held transceiver (especially power supply voltages required), Eico model 425 oscilloscope, and the Sentinel Electronics ME-26D/U multimeter (possibly a military version of the HP-410B). I will gladly pay any reproduction or postage costs.

Frank Latos AC8P
11251 Chicago Rd.
Warren MI 48093

Microcomputer Interfacing

from page 14

the computer is only dedicated to the loop for a short period. For other types of converters, the conversion time may take much longer, perhaps milliseconds or even hundreds of milliseconds for a digital multimeter. In such a case, the microcomputer would spend considerable time waiting for the ADC to "flag" the 8080, indicating that the conversion was complete.

An alternative approach is to use the DONE/$\overline{\text{BUSY}}$ flag as an interrupt input to the 8080. After initiating a conversion by outputting a START pulse, the microcomputer goes to some other software task while the conversion is proceeding. When the conversion is complete, the ADC interrupts the computer and points it to the ADC's service software, which, in this case, is located at 000 070. A software example is provided in Table 2.[2] In this example, the ADC subroutine is used only to start the conversion process. The subroutine at 000 070 is called by the interrupt with the aid of a jammed RST7 instruction byte. The ADC interrupts the 8080 only when it has finished a conversion. The software starting at 000 070 inputs the ten bits of data and stores them in a data file. Interrupts should be used with caution.

LETTERS

from page 8

thing couldn't be that dead after taking only ten pictures. So, anyway, I put it on a VOM and discovered that it is a little better than six volts.

I temporarily put a 12-volt light bulb on the contacts and was surprised to find that it lit up quite brightly.

The next thing I did was put a motor on it that came from an HO electric train, and it ran quite well.

It seems to me that if someone were to lower the voltage a bit and use it to power things like LEDs, it would last quite a while. I had no way of telling how long it would have lasted with this continued use. I'll try that next.

However, it says on the film pack not to take the thing apart, but to throw it away.

If one were careful, you could put it to some use, after, of course, taking ten pictures with your Polaroid.

I wish you would try one out on something and let me know how it worked or if it is a good idea.

Jerry Smith WA2QEL
Port Crane NY

THANKS, UNCLE!

My main comment is about the letter in the September issue of *73* by KA2RF. I held the callsign WA2UUV for about seventeen years. I moved to California and received orders to the *USS Midway* CV-41 homeported in Yokosuka, Japan. Meanwhile, tiring of having to sign portable after my callsign, I applied for a counterpart callsign for the sixth call area (K6UUV was open) and received KA6CGF instead. My ticket has my home QTH on it, but the envelope was addressed to my military address aboard ship. So what do I do—sign portable in Japan or in the States? Head for the CPO club and put away a few 807s or take up knitting in my spare time? Can I legally operate in JA-land or what? As you see, once again Uncle has put me between a rock and a hard place.

I enjoy your tilts with the ARRL; sometimes trying to get the point across to them is like trying to get the attention of a Missouri mule—it takes a few raps with a verbal 2x4, but eventually you get its attention.

Bill Fulling KA6CGF
FPO San Francisco CA

COLLINS

Although Collins continues to offer only their vacuum-tube line of transmitters, receivers, and transceivers on the amateur radio market, they have introduced a solid-state line for commercial use. Two of the new transceivers, the HF-281 and the HF-282, have an output of 125 Watts. For commercial use, they are channelized but can be adjusted to any frequency between 1.6 MHz and 30.0 MHz in 100-Hz increments. A "clarifier" control permits excursions 150 Hz above or below the established frequency.

With the HF-281, the user may select among six preset channels. The HF-282 offers 20 channels as well as a plug-in PROM IC to permit additional 20-channel ranges to be readily available.

Each of the two models includes a built-in ac power supply for 50- or 60-Hz 115- or 230-volt operation. In addition, either may be operated from a 12-volt dc power source. Optional features include VOX, squelch, and a noise blanker.

For operation with a variety of antennas, a companion antenna coupler, the HF-280, enables use of antennas ranging from a short whip to random-length "longwires." It is not stated whether this matching device tunes automatically or must be manually retuned for major frequency changes.

It is not known whether Collins has any plans for putting similar equipment on the amateur radio market.

THE RIGHT TO RULE

I read K7UL's letter in the September issue of *73*. I am really disappointed with his and apparently your opinion about the USA and other countries in the ITU.

Indeed, the US is a first-rate power (economic, military, etc.), but this does not give it the right to rule the world.

Because you live in a democracy, you know better than I that everybody's vote is equal. Otherwise, why not give Mr. Rockefeller or Mr. Kennedy more votes than Mr. Joe Smith in a US election?

Sorry for the *bad* English, but I am from an underdeveloped country that does not speak your language.

VE3TEN

On December 29, 1978, on a frequency of 28.172, station VE3TEN did QRM this frequency from 1600 GMT to 1715 GMT. It laid down a carrier and every 15 seconds or so IDed as VE3TEN. Look this one up in the *Callbook*. It belongs to the Canadian branch of the ARRL. What gives them special license to QRM the band? I feel this was in bad taste and I would like to have *73* find out just what they had on their minds. I called the ARRL in Connecticut and got a real pleasant runaround. They sure did make an impression on future hams.

Name submitted but

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

WHICH PAGE DO YOU READ?

On page 6 of the March issue of *Ham Radio Horizons* (also reprinted in *HR*), an editorial discounted the gloom and doom reports about WARC, saying G&Ders "apparently get their information from the Wizard of Oz—or some other equally unlikely source." On page 11 of the same magazine, a wizard tells us in the lead item of Newsline that broadcast interests are threatening us at WARC. Some schizophrenia there?

There was no specific mention of anyone in the editorial, just a few straw men set up and toppled. Since I've written about WARC recently, I tried to identify any possible references to my writing, but failed. Like the League, I feel optimistic and agree with them that the ITU *can't* kill amateur radio. It is unthinkable and I am not thinking it. I do regret that something positive wasn't done just to make sure, particularly in the face of the massive losses amateur radio has suffered in recent years—and I consider the loss of 239,000 MHz of satellite microwave ham allocations a massive loss. *Ham Radio Horizons* knows all about this loss and just ignored it.

They also know about the meetings in the next few weeks between the African and Latin American lesser-developed countries (LDCs), which are for the express purpose of shooting down the US position at WARC. These are the countries which may well swing the tide at WARC ... and they are not friends of amateur radio.

But these are things which won't have much of an impact on us, even if the worst happens, for many years, so why get all exercised over something over which we no longer have much control? For the next few years, we are going to be in the middle of a sunspot maximum . . . DX will be good . . . the VHFs will be hopping . . . and we will have more exciting new modes coming along than most of us can handle.

If amateur radio really gets clobbered at WARC, perhaps we can use the years before our country agrees to the new allocations to do some of the lobbying for amateur radio in the LDCs that we should have done in the last year . . . and perhaps turn things around. We sure need a worldwide lobbying effort to bring the value of amateur radio to smaller countries out in the open. I'm optimistic.

1979 HAM INDUSTRY CONFERENCE

With our fourth annual ham industry conference in Aspen, new records were set. For instance, I think that this was the fourth year in a row that our confirmed reservations on either Rocky Mountain or Aspen Airlines were met with a slight smile and a shrug of the shoulders when we came to their departure desk at Denver.

Hertz and Avis were up to the situation ... no cars available for us to drive to Aspen. National really was geared for this . . . they had one car available, but with a $250 charge if we dropped it at Aspen . . . take it or leave it. We grumbled a whole lot, but we took it.

The four of us, Sherry Smythe, Chuck Martin WA1KPS of Tufts Electronics, Eric Williams WA1HON, and I drove over the mountains some 200 miles to Aspen. The road was icy most of the way, but we still made good time, after what is becoming a ritual dinner at Holly West in Denver before our annual drive to Aspen. Chuck played bluegrass on his guitar through much of the trip and we all sang as we went over the mountain passes.

The snow in Aspen was superb, as usual.

On the first evening, we had our worst meal of the week . . . a cheese fondue at Guido's Swiss Inn. Ugh. It sort of discouraged much of the shop talk that usually accompanies our meals in Aspen. But the next night we did much better at the Copper Kettle. It was there that we had our first coincidence.

I had just finished handing out some brochures from an advertising agency in New York which was pitching ham businesses to use a ham-run agency. We were all sitting around reading the brochures when the

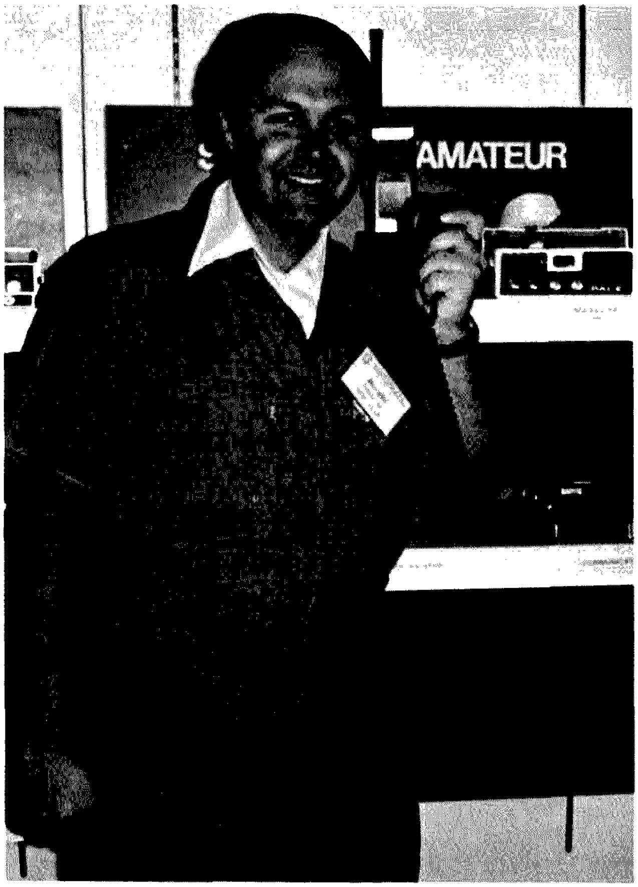
CES '79

CES: three letters with a lot of meaning to the American economy. These letters stand for the Consumer Electronics Show, a twice-yearly gathering of all those who manufacture and sell the myriad of electronic and electronic-related products which wind up in your home and mine. During the summer, the city of Chicago plays host to this gathering, but come January, it's Las Vegas where the action is.

Residing in southern California has certain advantages. Other than writing for this magazine, I earn my keep from consumer electronics, and a show like this is one I do not want to miss. Las Vegas being but a 45-minute flight or five-hour drive, I try to be in attendance when such events take place. Mother Nature being kind and keeping I-15 open made the decision to drive an easy one. Armed with my 35mm camera, extra film and batteries, a Clegg FM-27B, and a Midland 13-509, I aimed the nose of my Ford Maverick northeast along California Highway 14. Destination: the Hilton Convention Center in Las Vegas.

Two pieces of advice to anyone planning to attend a trade show such as this. First, get a good night's sleep before going. Second, buy the most comfortable pair of shoes your budget will allow. Also, if like me you intend to photograph things, get the lightest camera and strobe you can find.

The CES is the place where everyone who is anyone shows everything. There are televisions, radios of every description, VCRs, home computers, and even amateur radio gear. That's right, amateur radio. Ham gear seems to be playing a more and more significant role in this show each year. In the past, it had been CB which had cornered the personal communications aspect of CES, with amateur radio ranking a distant last. This year, however, perhaps due to the teetering condition of the CB industry in relation to its past performance, amateur radio and related products were right up there with the rest. Wilson had their entire amateur product line on display, as did a number of others such as Pace, Lunar Electronics, and Sujitsu-Ten. In the peripheral department, there were such standbys as Antenna Specialists, Hy-Gain, Hustler, and a new entry to the amateur market well known to CB enthusiasts: Avanti. In fact, Avanti has come into the amateur market with a most-advanced line of fixed station and mobile antennas, including a gain antenna for two meter mobile operation which requires no holes in the vehicle and no external wiring. You simply glue it to the window and plug it into your radio. They have a similar one for 10 meter enthusiasts, as well as a diversity beam which permits you to adjust polarization from your shack. All in all, a very interesting arrival in the amateur marketplace.



Bill Cody demonstrated the new Pace 2 meter rig at the CES.

You could easily tell the hams at the show. There was no need to look for badges—very few were visible. The hams were the ones playing with radios like the new NDI or Pace or Midland entries. They were to be found examining handhelds and antennas at the various booths. No one knows how many of the 66,000 attendees were amateurs, but there sure were a lot of them and they were not hard to spot.

Hustler, Midland, Pace, and the rest. These are all names familiar to those of us who are involved in the amateur radio game. I'll tell you one thing, though. It was nice to see them giving the amateur service the kind of exposure it needs in a place where so many could see it. CES was great. Amateur radio's representation was about 1%, I guess, but that was good. Better than ever!

THE WHATEVER HAPPENED TO HIM DEPARTMENT

Richard B. Cooper. Now, that name should ring a bell with you. No? How soon we forget. Last year a man calling himself Richard B. Cooper and professing to be an attorney startled the amateur community with such announcements as a lawsuit against the ARRL and his intentions to "grab" at least half of the current amateur spectrum for expanded CB. "Rick," as he called himself, was really making a name for himself. Then suddenly he just vanished from sight! It became impossible to contact either Cooper or the "law firm" he claimed to own: the Communications Attorney Service. Where has he gone? Your guess is as good as mine. What has happened to him over the last year or so is really what is of interest.

It seems that amateurs were not the only ones interested in Rick Cooper and his Communications Attorney Service. Rick was making a lot of claims back then as to the power and scope of his organization, its goals, and its membership. Eventually the matter drew the attention of the Office of the Attorney General of the State of California. An investigation by the Attorney General's office led to a formal civil complaint against Cooper, CAS, and Does 1 through 20, inclusive. The complaint, case #0233123, was filed in March of 1978 in the

Mr. and Mrs. Lou Anxiaux of Lunar Electronics. Lou (WB6NMT) was author of the VUAC's 2 meter band plan.

Novice, QRP, 200 w, deluxe — good, better, best — $299, $369, $399, $699, $869, $899, $1069. TEN-TEC has them all. A choice of seven HF transceiver models — a choice of power levels — a choice of operating features (and accessories) for beginner or old timer. Best of all, there's a wide choice of prices to fit every amateur budget.

TEN-TEC "OMNI" TRANSCEIVERS — REALLY CHOICE.
Top of the line. Deluxe in every respect. Deserving of a place in the finest of operating positions. All solid-state 100% duty cycle 200-watt final amp.; 8-bands (160-10 m plus convertible 10 MHz and "Aux" band positions); broadband design for no tune-up; built-in VOX and PTT; built-in Squelch; 4-position CW-SSB filter and 8-pole crystal filter with separate mode switch to permit using all filters in all modes; 2-speed break-in; 2-range offset tuning; optimized sensitivity from 2 μV on 160 m to 0.3 μV on 10 m; greater dynamic range (typically better than 90 dB) plus PIN diode switched 18 dB attenuator; WWV at 10 MHz; front panel control of linear/antenna bandswitching; phone patch jacks; "timed" crystal calibrator (on "A" model only); zero-beat switch; SWR bridge; adjustable ALC and sidetone; dual speakers; plug-in boards; "clamshell" aluminum case with black vinyl covering plus warm dark metal front panel; full shielding, optimum size for convenient operation: 5¾"h x 14¼"w x 14"d. Model 545 OMNI-A with analog dial, only $899; Model 546 OMNI-D with six 0.43" LED digital readouts, $1069. Model 645 keyer, $85, Model 243 Remote VFO, $139, Model 248 Noise Blanker, $49, Model 252MO AC Power Supply, $119.

TEN-TEC "ARGONAUT" TRANSCEIVER—QRP CHOICE.
The challenge and excitement of working the world on 5 watts. And every feature you need: all solid-state; 5 bands (80-10 m); full amateur band coverage SSB/CW; sensitivity less than 0.5 μV; offset tuning; 4-pole IF crystal filter, 2.5 kHz bandwidth; analog dial; vernier tuning; automatic sideband selection; built-in speaker; 5-watt input to broadband push-pull final amplifier; PTT; full CW break-in; adjustable sidetone volume and pitch; built-in SWR bridge; TVI filter; plug-in boards; small and light weight enough to go anywhere (4½"h x 13"w x7"d and 6 lbs.). World beating price, too: Model 509 only $369; Model 210 AC Power Supply just $34.

TEN-TEC 540/544 TRANSCEIVERS—POWER CHOICE.
200 watts from the bottom of 80 m to the top of 10 m — SSB or CW. No compromise from the leader in solid-state HF technology. Instant band change without tune-up; sensitivity 0.3 μV; offset tuning; 8-pole crystal-lattice filter; WWV at 10 & 15 MHz; push-pull solid-state final amp.; 100% duty cycle; adjustable ALC with LED indicator; built-in SWR bridge; PTT; full CW break-in; adjustable sidetone pitch and vol.; zero-beat switch in Model 544. Choose the value leading Model 540 with analog dial and built-in 25 kHz pulsed calibrator for just $699 or the Model 544 with six 0.43" LED digital readouts for $869. Model 240 160M converter, $110; Model 262M AC Power Supply with VOX, $145; Model 252M AC supply only, $119.

TEN-TEC CW TRANSCEIVERS—BUDGET CHOICE.
The "Century 21" series. Unique. Modern technology with old-fashioned value. Fine performance, reliability, and simplicity of operation, all at low cost. Win raves from novices and confirmed brass pounders alike. All solid-state; 5 bands (80-10 m) full amateur band coverage; receive CW and SSB, transmit CW; sensitivity 1 μV or less; offset tuning; 3-position selectivity (2.5 kHz, 1 kHz, 500 Hz); 70 w input to push-pull Class C final amp.; broadbanded for no tune-up or resonating; full break-in; adjustable side-tone level; built-in AC power supply. Choose Model 570 with analog dial for only $299; Model 574 has a 5 LED digital readouts for only $399.

The choice is all yours when you choose TEN-TEC HF transceivers; see your nearest dealer or write for full details.

WIDEST CHOICE IN HF TRANSCEIVERS: TEN-TEC

John Clark (right) of the ARRL displayed League publications at CES '79.

Superior Court of the State of California for the County of Los Angeles. It asked that the court issue an injunction against Cooper and his CAS on five specific violations of both the civil and business/professions code of the state of California, and further requested that the court exact monetary penalties on each count of each violation.

Cooper was served the necessary documentation and at that point dropped out of sight. Nothing has been heard from him since. According to Assistant State Attorney General Herschel T. Elkins, who has been handling the Cooper/CAS matter, Cooper lost the case by default. Shortly, a hearing will be held to set the penalties in this case. Collecting them may be another matter. Cooper, as elusive as a fox, has disappeared without a trace. If you happen to know of Rick's whereabouts, you might drop a note to Mr. Elkins or to me. A lot of us would like to know what ever happened to Rick Cooper.

220—A LATE-BREAKING DEVELOPMENT

The 220-MHz Spectrum Management Association of Southern California (220-SMA) has filed a formal petition for reconsideration on FCC docket 20271, the document recently issued by the Commission relative to US WARC preparations in which maritime is made the prime user of the spectrum between 216 and 225 MHz.

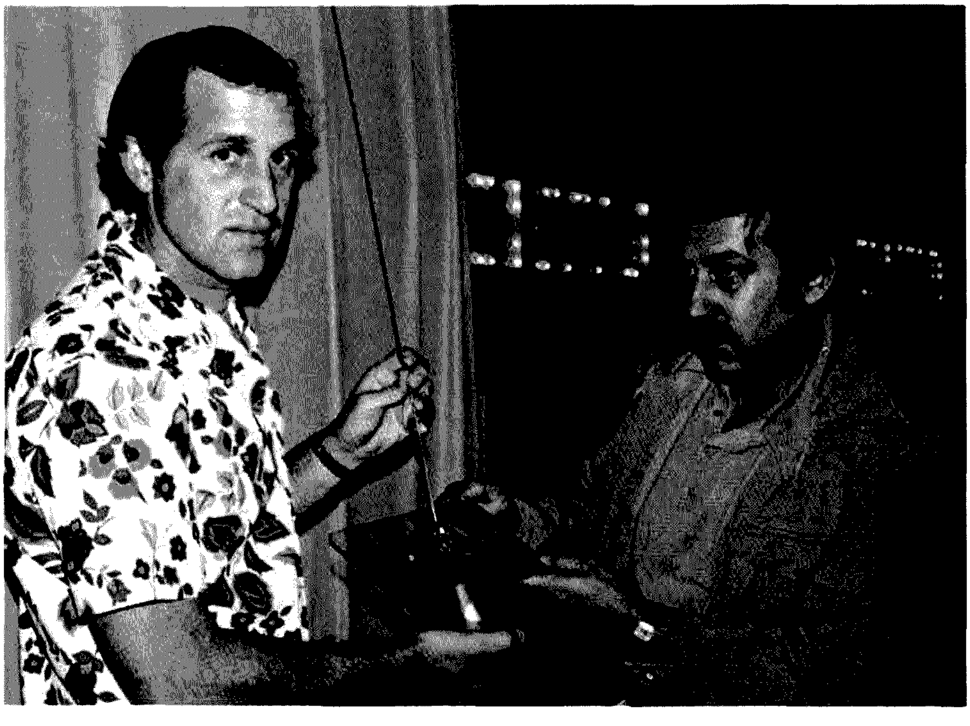
In its appeal, 220-SMA states its belief that representatives of the amateur service have not been given their chance under the structure of administrative procedures to properly comment on the proposed sharing with the maritime mobile radio service. 220-SMA goes on record as opposing the suggested reallocation and suggesting an allocation within the 890-MHz spectrum be considered as an alternative, in that such spectrum would be available worldwide since it has little or no utilization at this time. Implementation of a maritime mobile service in that spectrum would not displace any established activity and would have little environmental impact throughout the entire world.

The petition was prepared by 220-SMA advisor Henry R. Von Neumann K6PUW at the direction of 220-SMA President Larry Mohler WA6DOD, and was derived from Input obtained at a joint meeting of 220-SMA, 2mASMA, ARRL Director Holladay, and other VHF spectrum users. VRAC's local representative and the Southern California Repeater Remote-Base Association both declined to attend or take part in the initial planning on this matter, but did ask to be kept informed as matters progressed. However, 2mASMA, along with other local special-interest groups, is expected to endorse the petition, and 220-SMA is requesting that letters of support from coordinators, coordination councils, and individual amateurs be sent to the Commission as soon as possible. Those writing on the subject should refer to 220-SMA petition number 790120, submitted January 22, 1979. It's felt that enough support from the general amateur community might well force the Commission to give this petition serious consideration and perhaps reopen commentary on the matter.

CAN AND WILL THE ARRL SAVE 220?

"220 CB is dead and the ARRL slew it." With that statement, the League tried to take full credit for saving 220 MHz from the onslaught of "10-4 Good Buddy" and the evils that "10-4" would bring with him. They gave only the most abbreviated passing credit to the people who really counted, and never came near to telling the real story of what killed the 220 CB idea. I've heard quite another story. The big rumor is that formal objections from our neighbors north and south are what killed it, not the ARRL. If true, it makes a lot more sense, and I tend to believe it. Let's look at the present situation and the ARRL's power in relation to it.

First, we must assume that there were other forces which really devastated the 220 Class E CB idea. Class E was being pushed by but one entity, the EIA. For the EIA, this was a good move from an economic standpoint. It's a fact that it costs less to manufacture a radio for a lower frequency than for a higher one. This holds true even with today's advanced linear IC technology and mass production. So, if you were running an organization which represented the vast majority of those manufacturing two-way radio equipment, what would you do? You would look around at all spectrum and forge a viable attack to gain some more. When studies of available spectrum were made some years back, the 220-MHz



An Avanti rep explained the new no-holes 2 meter antenna to Bill Orenstein KH6IAF (right).

Continued on page 28

OMNI HAS IT *ALL*. All the advantages and capabilities, all the new conveniences and new levels of performance you need, whatever your HF operating specialty. All built-in, ready to use.

***ALL* SOLID-STATE.** All the advantages of total solid-state from the pioneer of HF solid-state technology. Reliable, cool, stable — from receiver front-end to transmitter final.

***ALL* HF BANDS.** From 160 through 10 meters (and all the crystals) plus convertible 10 MHz and "AUX" band positions for possible future needs.

***ALL* BROADBAND.** Band changing without tuneup — without danger to the final amp.

***ALL* READOUTS.** Choose OMNI-A for analog dial (1 kHz markings) or OMNI-D for six 0.43" LED digits (100 Hz readability.)

***ALL* VOX AND PTT FACILITIES** built-in; 3 VOX controls plus PTT control at front and rear jacks for external PTT switch.

***ALL* SQUELCH NEEDS** for tuning and monitoring are built-in.

***ALL* FILTERS INCLUDED:** 4-position CW/SSB filter (150 Hz bandwidth with 3 selectable skirt contours) plus 8-pole Crystal filter (2.4 kHz bandwidth, 1.8 shape factor.)

***ALL* MODE SWITCH** puts all filters to work in any mode.

***ALL* BREAK-IN:** Instant or delayed receiver muting to fit any band condition or mobile operation.

***ALL*-VERSATILE OFFSET TUNING;** dual ranges, ±5 kHz range for off-frequency DX or ±0.5 kHz range for fine tuning.

***ALL*-SENSITIVE RECEIVER;** from 2 μV on 160 m to 0.3 μV on 10 m (10 dB S+N/N) for ideal balance between dynamic range and sensitivity.

***ALL* OVERLOADS HANDLED;** dynamic range typically exceeds 90 dB and PIN diode switched 18 dB attenuator also included for extra overload protection.

***ALL* LINEAR/ANTENNA BANDSWITCHING FROM FRONT PANEL;** auxiliary bandswitch terminals on back panel for external relays or circuits are controlled simultaneously by the OMNI bandswitch.

***ALL* INTERFACE JACKS FOR PHONE PATCH;** access to speaker and microphone signals.

***ALL*-LEVEL ADJUSTABLE ALC;** set output from low power to full, retain low distortion at desired drive to power amp.

***ALL* SIDETONE ADJUSTMENTS;** pitch and volume.

***ALL*-POWERFUL, *ALL*-WARRANTED FINAL AMPLIFIER.** 200 watts input to final. Proven design with full warranty for first year and pro-rata warranty for additional 5 years.

***ALL* 100% DUTY CYCLE.** For RTTY, SSTV or sustained hard usage.

***ALL*-MODE POWER:** basic 12 VDC for easy mobile use, external supplies for 117/220 VAC operation.

***ALL* FRONT PANEL MICROPHONE AND PHONE JACKS.** Convenient.

PLUS *ALL* THE OTHER HANDY BUILT-INS: "Timed" 25 kHz crystal calibrator in OMNI-A with automatic 5-10 sec. "on" time for easy 2-hand dial skirt adjustment... Zero-Beat switch for placing your signal exactly on CW listening frequencies... SWR bridge switches "S" meter to read SWR each time you transmit for continuous antenna monitoring... Separate receive antenna capability... Dual speakers for greater sound at lower distortion... Plug-in circuit boards for fast, easy field service.

***ALL*-FUNCTIONAL STYLING.** "Clamshell" aluminum case clad in textured black vinyl with complementary nonreflective warm dark metal front panel and extruded aluminum bezel and bail. Convenient controls. Complete shielding. And easier-to-use size: 5¾"h x4¼"w x 14"d.

AND *ALL* THE OPTIONS: Model 645 Keyer, Model 243 Remote VFO, Model 248 Noise Blanker, Model 252MO AC Power Supply.

Model 545 OMNI-A $899 Model 546 OMNI-D $1069

Experience the *all*-encompassing HF world of OMNI. See your TEN-TEC dealer or write for *all* the details.

TEN-TEC's "OMNI" FILLS *ALL* YOUR HF NEEDS

LETTERS

MACARONI

After reading "Diodes of the Dead" (*73*, Jan., 1979), I have diagnosed Mr. Dunn's problem. By using high-quality audio tape (Ampex "Grand Master" or Maxell UD35-90), I had absolutely no problem "calling up" two dead aunts and some guy calling himself "Macaroni." Also, I found by using a slightly larger antenna (10'-12'), Alpha Centauri comes in "Q5". 73.

Jerry Robinson III N4KJ
Asheville NC

BRUTAL

With only one element remaining to complete my Extra class ticket, I just had the misfortune to "close encounter" the brand new exam.

My advice: If you're not a mathematician, you'd better take a crash course before you attempt the test. It is a *brutal* mother.

This new Extra class series (dated 9/78) features a central core of 20-or-so questions, each one attached to a schematic. You'll be asked to compute complex reactances, impedances, resonant frequencies, or missing component values at some arbitrary point in the circuit. No formulas are provided, and most of the values you'll be asked to compute *do not* relate easily to any of the material in any of the existing study guides.

The non-mathematical questions, by the way, are extremely esoteric and obscure. There is material on IC junctions, remote base regulations, 5 or 6 questions on SSTV and ATV, and other trivia from the fine print of the regs.

My hunch is that the FCC found itself rapidly running out of 1 x 2 callsigns and decided to plug the small conduit that lets new Extras through. They plugged it good and tight! Be warned. The test is not impossible—but you *will* need lots of math, and *we all* will need new, *competent* study guides—like pronto.

Incidentally, the exam itself is atrociously edited—with numerous typographical mistakes, misspelled words, and my copy even had the wrong element class printed on the cover! The word "ADVANCED" had been pasted over with a sticker that said "EXTRA." My confidence in Uncle's competence was not enhanced.

By the way, fellas and gals, if you haven't yet listened in on the "secret" pseudo-ham band that runs from 27.5 to 28 MHz (above CB and below 10 CW), you're missing some of the funniest (or most infuriating) SWLing of your life!

A recent spot check produced these gems:

1. A spiritualist in Houston who gives psychic readings and conducts on-the-air meditation classes every Sunday.
2. A cross-country SSB QSO between two chaps, one running a TS-820, the other a Yaesu FT-101, shooting the breeze about how they're progressing toward their NOVICE tickets!
3. Someone conducting very graphic, on-the-air sexual counseling via radio.
4. A slow-scan TV signal!
5. Many, many individuals who indicated that they also hold amateur licenses and operate (legally) on other bands.

This latter finding is the most surprising of all. Maybe it's the anarchist spirit having a go—or simple boredom with the routine and formality of the "disciplined" amateur bands. It's certainly true that 11 is a hotbed of radical and innovative radio doings—the likes of which you're not likely to hear anywhere else.

A man in Italy "skeds" his relatives in New York City each morning.

A woman in South Dakota has regular radio pen-pals from Europe to Australia.

You'll even hear high-speed CW QSOs on this crazy band—complete with "Whiskey Club" numbers for ID! It's beyond me why an op who can handle 20 wpm takes his business down there. But turn up your ears and check it out for yourself. There they are.

I will say one thing about the foreign stations who are using "secret band" to sked relatives in this country. I try to imagine these relatively easy, hassle-free contacts taking place in the licensed amateur service, where the DX station would *immediately* be pounced upon by the prick-eared wolf pack, and all hopes of a relaxed rag chew would vanish. I do begin to understand what may be driving even licensed hams to this virgin frontier!

Could it be a radio revolution in the making? Or the prelude to a determined FCC crackdown? Only time will tell. In the meantime, something is definitely happening at one of our borders. It behooves us to listen and evaluate the phenomenon.

VOYAGING

The JPL Amateur Radio Club, through its club station W6VIO (*V*oyager *I*n *O*uterspace), will repeat its performance during the *Viking* landings on the planet Mars by holding commemorative contacts during the forthcoming (actually, now in progress) *Voyager* mission to the planet Jupiter.

The spacecraft *Voyagers I* and *II* are currently engaged in the first observational phases of their mission of exploration of the planets Jupiter and Saturn.

Among the data being returned will be pictures of the disc of Jupiter at various distances showing details of the planet that it is not possible to see with any terrestrial telescope of known configuration.

On slow-scan TV, these and other pictures will be sent out for amateurs to see throughout the world.

According to Dick Piety K6SVP, the project coordinator, the first contacts will have been made March 1 through March 11, 1979. This coincides with the encounter phase of the first of the *Voyagers* to arrive near Jupiter. A second encounter period for *Voyager II* will bring on more amateur contacts July 6-15.

The following frequencies will be used plus or minus QRM: CW—30 kHz above bottom edge of the bands, 80 through 10 meters. SSTV—3545, 7220, 14325, 21340, 28680. Novice—3730, 7130, 21130, 28130. SSB—3930, 7230, 14285, 21360, 28680. OSCAR—2 meters and 220-MHz transmissions are planned as well.

As presently set up, the plans call for heavier operations on weekends and between the hours of 4:00 pm and 7:00 pm PST (0000 to 0300 Zulu).

The JPL Amateur Radio Club regrets that it does not have a special commemorative call such as the N6V used during the *Viking* mission. However, W6VIO will issue a special QSL card for the *Voyager* commemorative. An SASE is requested from U.S. stations. DX stations may QSL via their QSL bureaus.

Pasadena CA

VITRIOL

It would almost be worth buying occasional copies of *73* to see if this letter changes an approach—and if it gets printed under "Letters"—but the odds are against it. Recently there was a debate at the UN between representatives of Vietnam and Cambodia. A TV commentary stressed that although each side called the other liars, it was on a higher, diplomatic, and less corrosive level than a previous controversy when Khrushchev took off a shoe and pounded the table with it. What has this to do with *73*?

Many years ago, almost when you first started *73*, I regularly purchased copies and think even subscribed for a year or so. However, the vitriol dripping from your pen so turned me off that I stopped reading it. Recently, a ham whom I regularly work touted *73*, so I bought two copies.

Even granting that the ARRL could do a better job for ham radio, that it tends to pigeonhole ideas of others, that it is biased against women, and that it is dictatorial in many ways, is it possible that a more affable indictment in publishing their shortcomings would present your ideas in a more acceptable way to your readership and (if a miracle occurred) to the ARRL?

So what do I like about *73*? The December issue had "Close Encounters," which supplied completely new knowledge of use of lasers in a study of UFO phenomena, "From CW to Computers," an interesting presentation of a technique previously known, "DX," a well-concocted column, "Receiver Diseases," some simple ideas in easily readable fashion, "The Packet Radio Revolution," again an informative article. In the January issue, "Time-Domain Reflectometry" answered my ignorance on how public utilities pinpoint problems, and, if I had a scope, a good test technique.

Although doing some necessary home brewing in 1923 (call 2AST) and some since, I am primarily an appliance operator. Making a PC board, etc., frightens me off, but I am able to make repairs to my two transceivers which are solid state. My interest is CW at 25 wpm up, except for one or two schedules per week on SSB with old-timers who have large-

15 Windsor Dr.
Atco NJ 08004

ANNUAL APRIL QRP QSO PARTY

Starts: 1600 GMT
Saturday, April 7
Ends: 2400 GMT
Sunday, April 8

The contest is open to all amateurs and is sponsored by the QRP Amateur Radio Club International, Inc.

Stations may be worked once per band for QSO and multiplier credits. Each member QSO counts 3 points, non-member QSOs, 2 points. Stations other than W/VE count as 4 points per QSO. Multipliers are as follows: more than 100 Watts input power—x1; 25 to 100 Watts—x1.5; 5 to 25 Watts—x2.0; 1 to 5 Watts—x3.0; less than 1 Watt power—x5.0.

Final score is QSO points times total number of states/provinces/countries *per band* times power multiplier.

EXCHANGE:

Members—RS(T), state/province/country, QRP number.

Non-members—RS(T), state/province/country, power input.

FREQUENCIES:

CW—1810, 3560, 7060, 14060, 21060, 28060, 50360.

SSB—1810, 3985, 7285, 14285, 21385, 28885, 50385.

Novice—3710, 7110, 21110, 28110.

All frequencies ±5 kHz.

ENTRIES:

Send full log data, including full name, address, and bands used. Indicate equipment, antennas, and power used. Include a #10 SASE for results. Logs must be received by April 30, 1979, to qualify. Send logs to: E. V. Sandy Blaize W5TVW, 417 Ridgewood Drive, Metairie LA 70001.

Certificates will be awarded to the highest scoring station in each state/province/country, and other places depending on activity. One certificate for the station showing three "skip" contacts using the lowest power.

BERMUDA AMATEUR RADIO CONTEST

Starts: 0001 GMT April 21
Ends: 2400 GMT April 22

Sponsored by the Radio Society of Bermuda. Operate no more than 36 hours of the 48-hour contest period. Off periods to be clearly logged and each period to be of not less than 3 consecutive hours.

All stations shall be single operator only and must be operated from their own private residence or property. Each station may be worked only once per band regardless of mode. Use all bands 80 to 10 meters, but no crossband or crossmode contacts permitted.

EXCHANGES:

All stations exchange RS(T) and following: UK—county, US—state, VE—province, Bermuda—parish, West Germany—DOK #.

US and VE stations must exchange reports with UK, West German, and Bermuda stations only. UK and West German stations must exchange reports with US, VE, and Bermuda only.

***County or section winner**
****Grand Connecticut or out-of-state winner**

Each QSO = 5 points. Multiplier for all stations outside Bermuda is the total number of VP9s worked on each band. The same VP9 can be worked on all bands. For Bermuda stations, it is the total number of states, provinces, counties, and DOK #s worked on each band.

AWARDS:

Top scorer in each state, province, county, and DOK area in West Germany shall receive a certificate. Trophy to top scorer in VE, US, UK, and West Germany. Round-trip air transportation plus accommodation will be provided to overseas winners to enable them to receive their awards.

ENTRIES:

All dates and times in GMT. All contestants to check for duplicates and to compute their own scores. Sign a statement that all rules and regulations have been observed. Each page must be clearly marked with call, name, and address, and must be received by the contest committee before June 30. Send entries to: PO Box 275, Hamilton 5, Bermuda.

Note: Please submit a log if you operate in the contest. This

PUBLICATIONS CONTEST RESULTS

Results ol the Amateur Radio News Service 1978 Publications Contest have just been released by judges Norm Monro K4FRY, Vivian Douglas WA2PUU, and Dan Dolan K4RN.

Submissions for this contest were divided by publisher and size into two groups. Group I consisted of club papers: I(a). less than 100 copies; I(b). 100-199 copies; I(c). 200-299 copies; I(d). 300-399 copies; I(e). 400 or more copies. Group II contained multi-club papers: II(a). less than 1000 copies; II(b). 1000 or more copies.

The club presidents of the winning entries will receive certificates to be presented to their groups. All editors will be receiving the judges' comments by personal letter. Congratulations to the following:

Group I:

I(a): First prize: *The Salami Merchant*, Silvercreek Amateur Radio Association, Doylestown OH 44203. Al D'Aurelio W8WKY, Editor.
Second prize: *Hamtrix*, West Allis Amateur Radio Club, Inc., Milwaukee WI 53211. David J. Knaus WA9POV, Editor.
Third prize: *Mid-Sussex Matters*, Mid-Sussex Amateur Radio Society, Burgess Hill, East Sussex, England. Alfred Lee G4DQS, Editor.
I(b): First prize: QCC *News*, Chicago Area Chapter, QCWA. Lee J. Knirko W9MOL, Editor.
Second prize: *66/06 Newslines*, Westchester Emergency Communications Association, North Tarrytown, New York 10591. Mervin Genzer WA2HZD, Editor.
Third prize: *The Call Letter*, Poway Amateur Radio Society, Poway CA 92064. Glen Peterson WB6BOD, Editor.
I(c): First prize: *QUA*, Warrington Area Repeater Association, Warrington PA 18976. Bruce Gilman WB3CFE, Editor.
Second prizes (ties): *The Orbit*, The Satellite Amateur Radio Club, Vandenberg Air Force Base CA 93437. John E. Douglass WA6EZZ, Editor. *FM News*, UK FM Group (London), London, England. Alan D. Gray G8LCO, Editor. *Ham Rag:* Rockford Amateur Radio Association, Rockford IL 61110. Darrell B. Crimmins WD9FVG, Editor.
Third prize: *Red Rose Repeater Association (Newsletter)*, Lancaster PA 17601. Martin Bloomberg WA3MHP, Editor.
I(d): First prize: *Carrier*, Mt. Diablo Amateur Radio Club, Inc., Pleasant Hill CA 94523. Harold S. Mumford W6CU, Editor.
Second prize: *Cheese-Bits*, Mt. Airy VHF Radio Club, Inc., Elkins Park PA 19117. Harry B. Stein W3CL, Editor.
Third prize: *QRZ*, Rocky Mountain Radio League, Golden CO 80401. Jim Labo KØQST, Editor.
I(e): First prize: *Amsat Newsletter*, Radio Amateur Satellite Corporation, Washington DC 20044. Joe Kasser G3ZCZ, Editor.
Second prize: *The Round Table*, The Denver Radio Club, Denver CO 80202. Robert N. Jensen W9WLN, Editor.
Third prize: *The Modulator*, Baltimore Radio Club, Inc., Baltimore MD 21203. Roland Slatkoff W3RUN, Editor.

Group II:

II(a): First prizes (ties): *Mobile News*, Amateur Radio Mobile Society, Purley, England CR2 1EZ. Norman A. S. K. Fitch G3FPK, Editor. 220 *Notes*, edited by Julian N. Jablin W9IWI, Skokie IL 60076. Bus. Mgr. is Virginia L. Sterling WB9UFW, Morton Grove IL.
Second prize: *CORA Collector and Emitter*, Central Oklahoma Amateurs, Inc., Oklahoma City OK 75155. Joe K. Harding WA5ZNF, Editor.
II(b): First prize: *Repeater Journal*, Carolinas-Virginia Repeater Association, Durham NC 27705. Wayne Williams K4MOB, Editor.
Second prize: *The Hamateur*, Edited by Larry McCalvy WA9JMO, Milwaukee WI. Honorable Mention: *Radio-Hobbyist Newsletter*, American Radio Council, Garland TX 75040. Frederick W. Mala W5YI, Editor.

DX PROFILE

This month's DX Profile is on Bob Geary 5Z4NH of Thika, Kenya, East Africa. The following is a letter from Bob describing his background and his life in Kenya:

"I first became interested in amateur radio in 1946 when I helped Larry W8VPA carry his BC-610 up the stairs. I have not recovered either my sanity or my back since then. I was first licensed in 1957 as K2ZLE and became interested in VHF as a member of the VHF Institute in New York City. I managed to work a VO1 from Brooklyn without the aid of a repeater, but I didn't realize that it was much of a feat until later.

"I arrived in Kenya in 1965 to take up the job of teaching chemistry in the Kenya schools. The courses here are the same as you would find in an American high school or junior college.

"Due to some very bad misinformation from a 'know-it-all' type who told me that I would not be able to get a license here in Kenya, I was off the air until 1972. Upon learning the true facts, I was readily and graciously issued a license by the Kenya authorities. It is interesting to note that an American can easily obtain operating permission here in Kenya, but that the reverse does not hold true for someone from Kenya trying to obtain operating permission in the US.

Bob Geary 5Z4NH.

"The people of Kenya come from a civilization and culture which is several centuries old. They are very gracious and kind to outsiders. In all my years here in Kenya, I have met only one Kenyan who was not a desirable person. The weather here is more pleasant than that of either Florida or southern California. In the highlands, the temperature ranges from 65° F in the evening up to about 85° F during the day. The rains, which come in two seasons, are heavy at times, but are warm and without strong winds. The sun shines better than nine hours a day during the dry seasons, and it is easy to develop a nice tan in only a short time. The coastal area is a bit warmer, but it is some 5,000 feet lower in altitude.

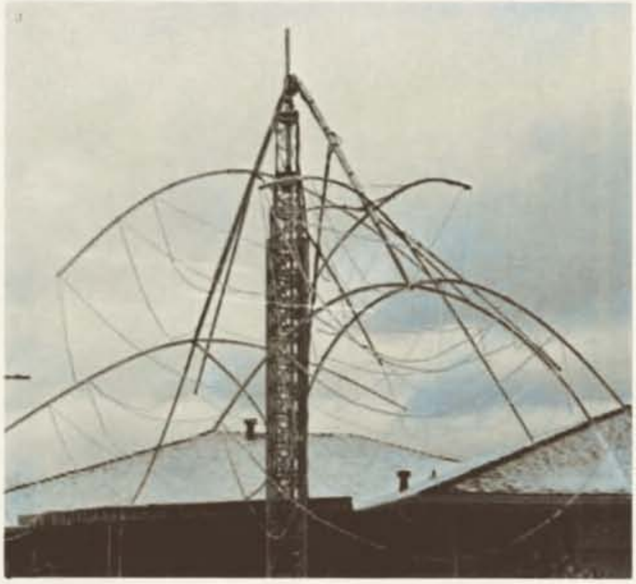
"The numerous recreation opportunities include golfing, boating, mountain climbing, camping, and, of course, the popular photo-safaris. Kenya is not only a great place to visit, but a perfect place to live as well. About the only inconvenience is having to wait until the giraffes pass before I can get to the school building some mornings. Being mute, the giraffe has few outlets for his anger; since they can kill a lion with one kick, I allow them plenty of clearance.

"Being in almost the center of the world's land masses, Kenya is a perfect amateur radio QTH. California, New Zealand, Chile, Japan, Alaska, and Antarctica are all almost equidistant from Nairobi. The elevation of 5,000 to 7,000 feet gives a perfect 360-degree downhill shot to the entire world. The low winds and easy availability of free bamboo make Kenya perfect for quad antennas. I have made better than 13,000 contacts in 250 countries without any special DX effort.

"Kenya 'Field Day' activities are functional, in that we supply communications for the annual East Africa Safari Race. The Radio Society of Kenya sets up a control station in Nairobi and dispatches members to some rather distant locations to set up and operate under horrible conditions. One year I drove 42 miles on a muddy road, set up the rig and contacted the control station, only to be informed that the race had been rerouted due to floods. I then repacked the gear and drove back to Nairobi, checked in, and was dispatched to another location, fortunately on the tarmac, but still wet and rainy. The volunteer stations are the only means of communication between the race organizers and the cars out on the course.

"Unlike field days in other areas of the world, you do not get to select your site. You are given a map reference and must hunt for your spot—and then try to get up some type of wire antenna for 40 and 80. Due to distances and conditions, verticals will not provide good results. A dipole is required for any degree of reliability.

"Usually, you do not get much chance to see any of the race activity because the cars come out of the bush, skid around a curve, slide to a stop, check in, and then roar off back around another curve into the bush again. Then there is the problem of crowd control. Little kids press around wanting to see what you are doing and are constantly in the way. Fortunately, the police, with a little judicious application of a switch from a nearby bush, usually can control the situation. The real kicker is when someone hears your call and



Before and after pictures of the editor's brand new quad. This was the result of the worst ice storm to hit Dallas in 30 years. The moral to this story is "Build it strong," even if you live in the sun belt. (Photos courtesy K5YUV)

tries to get a DX contact when you are having a rough time just hearing the control station.

"In normal times, I enjoy giving DX contacts, especially to the JA boys. They are good operators and are very good in standing by when you are working someone. If you express any note of complaint about a station, there will be a burst of Japanese on the frequency and the trouble immediately disappears for good. I can't understand the words but the meaning is clear.

"Stateside operators are usually well mannered in pileups, but there are a few who never seem to get the word. Fortunately, they are few in number and it is simple to make a list of their calls and ignore them. Another method is to give them a report to get rid of them and then forget to log their calls. I have worked one station five times in this manner and he still doesn't understand (until now) why he's never in the log.

"The great benefit of amateur radio is the really nice people I have met, especially on the Afrikaner and Clinker nets. I've made numerous contacts with these fellows over the past seven years and enjoyed every minute. To make a list of the guys who have offered to give any help needed would require several pages of fine print. I once asked for a copy of FCC Form 610 and received a copy from five different guys. These responses make life enjoyable.

"I would like to see an award given for the best QSL manager and I would like to nominate my manager, W2PPG, for the first one. I don't understand why these guys volunteer their services, but from the DX station's point of view it is greatly appreciated. I am a lot more likely to stay in and give a report to everyone who is calling when I know I won't have to miss a week of operating time filling out QSL cards. These guys are the unsung heroes of DXing.

"Well, that about covers everything from over here in Kenya. My best 73 to everyone, and if anyone needs Kenya, look for 5Z4NH any day between 21.300 and 21.355 MHz."

Gary (Grenfell) Morgan HS1ALT (ex-VE3JKD) can be heard almost daily on 20m. The QTH is Bangkok, Thailand—the only country operating from zone 26. On Thursdays and Saturdays, from 1414 to 1430 GMT, the Canadians Overseas Net is in progress, with HS1ALT, VS6CZ, and 5H3BP doing the guidance. Join this net, and you can fill your log with such prefixes as 7P8, DU4, YBØ, P29, G3, CN8, EL1, and VK, most of whom are Canadians abroad.

DX NOTEBOOK

Isle of Man GD/GT

DF7FH reports a planned DXpedition to the Isle of Man in July, 1979, to celebrate the 1,000th anniversary of the Isle of Man's parliament. During the first week of July, every station will be allowed to use the special GT prefix. They plan to operate from July 1st to July 15th on all SSB/CW bands. Operators include DF7FH, DK5FJ, DC1FP, DJ3BG, and YLs DF9ZG and DF9ZH. QSLs go to the individual operators.

Aves Island YVØAA

The Venezuela Amateur Radio Club is planning a DXpedition from April 7th to the 14th. Intended CW/SSB frequencies are 3525/3775, 7025/7085, 14025/14195, 21025/21295, 28025/28495-595. These are transmitting frequencies; listening frequencies have yet to be announced.

Heard Island VKØ

Several of the VK/ZL DXers have been gazing fondly toward Heard Island, and indications are that something may firm up before the year is out. Word has been passed that landing permission has been granted, transportation is on line, and even the callsign, VKØHI, has been issued. The last Heard Island activity was VKØHM back in the dark ages of 1970.

Christmas Island VR3AH

The following letter from WB4PRU gives some information and operating habits for those needing VR3AH:

"I am the QSL manager for VR3AH. I would like to pass along some sked times and

DXpedition QTH on the Isle of Man for the June/July operation by DF7FH, DK5FJ, DF9ZG, DF9ZH, DC1FP, and DJ3BG.

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Over the last several months, we have been investigating the components of a solid-state RTTY "stunt box," in hopes of putting together some kind of test equipment to send "THE QUICK BROWN FOX JUMPS OVER THE LAZY DOG." Along the way, it has occurred to me that even a simple identifier would be nice, like a "DE WA3AJR" or something. Hopefully, by the end of this month's column, we will be able to put something concrete together.

To date, we have covered interfacing to a loop (January, 1979), matrix encoding (February, 1979), and the UART with its associated circuits (March, 1979). If you are not familiar with these concepts, I suggest you check back to the indicated issues of *73*. If all is OK, plow on!

Let's start with the matrix. Assume space for encoding fifteen characters, with a switch to select which character is to be sent. You would have something like Fig. 1. Now, besides being expensive, fifteen-position switches are hard to turn using TTL voltage levels. So what we will use is the electronic version of a fifteen-position switch, a 74154 data distributor, shown in Fig. 2. By grounding both the enable and data input lines, the output selected in binary will go low. Now all we need do is provide the binary code to the input and watch the data select. By the way, before you get all huffy, I know that there are really sixteen outputs from this chip, but we will need the last one later. The binary code input can be provided by a binary counter chip, such as the 7493. The beginnings of a system can be seen in Fig. 4, where the counter sequences the data distributor, which subsequently selects the matrix element.

"OK, smarty," I hear you say, "where do we get the pulse to trigger the counter?" From the UART, naturally! Reviewing the inputs and outputs of the UART, one finds a pulse on pin 22 which goes high when it's all right to load a new character. Sounds useful, no? Just as useful, we shall see, is a signal output which signifies completion of transmission of the current character.

Enough of the preliminaries. Let's throw in some more gates to control all this logic and come up with something like the suggested circuit in Fig. 5. It's not too hard to dissect this rather formidable circuit if you start at one side and proceed through it, gate by gate. On the right we have a push-button, used to start things off, which is suitably debounced and conditioned into the negative pulse needed to start the UART off. This pulse is passed through two gates on the way to the UART: an OR gate which will accept either the push-button or UART signal to trigger the UART, and an AND gate, used to turn the whole thing off at completion of the message. As soon as the UART starts sending the character presented by the matrix, an "OK TO LOAD" signal appears on pin 22. This is sent to the counter, advancing one count, and presenting the next character to the UART. When transmission of the current character is completed, an "OK TO SEND" pulse appears on pin 24 and is used to trigger the UART to send the next character. When the last character in the matrix is sent, the next advancement of the counter selects the sixteenth line (I told you I would get around to it!) and grounds it. By using that line as one input of an AND gate and the "send" signal as the other, one can block the "send" by providing a logic "0" to the other input of the AND gate. That is, with a logic "1", as will be provided when the last character is *not* selected, the output of the AND gate will follow the input. A logic "0" on one input of an AND gate inhibits *any* output from the gate. Fig. 6 demonstrates this for the disbelievers in the crowd.

If one wished to send just a test, say "RYRYRYRY . . . ," quite a bit of simplification could be envisioned. Only two rows of a matrix would be needed, and a simple flip-flop could select the row in use. Further, a "start" and "stop" control could be integrated with one more bounceless push-button. Fig. 7 offers some suggestions along that line.

Expanding the data to more than fifteen characters is also possible, but is a bit more complicated. Fig. 8 is one possible solution. Here we have used an additional 74154 as a true data distributor which selects which bank of matrices gets selected. For now, this shall remain food for thought.

Are you all ready for the

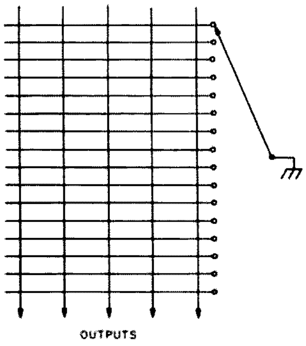

Fig. 1. Mechanical matrix selection.

record? The single item to draw the most response which I have ever mentioned in the two years of this column was the question as to the whereabouts of the *Green Keys* and *RTTY Journal*. While no one seems to know what happened to the *Green Keys*, oh, boy, do you all know about the *RTTY Journal*. I received numerous notices that it is *not* dead, although the exact state of its health was questioned by many readers. If you're interested, you might drop a line to: *RTTY Journal*, PO Box RY, Cardiff-by-the-Sea CA 92007. Subscriptions are currently $5.00 per year for the US, and $6.50 per year for Canada and Mexico. Foreign rates are also available.

Many thanks to the many hams who sent along information about *RTTY Journal*, including Larry Filby K1LPS, Mark Wilson W0ZSU, Howard Markwell W0MT, and John Langtry, who did not give his call but hails from Ontario. John also related that there is a Canadian RTTY magazine out, published by Gwen Burnett VE3AYL. Called *RTTY News*, the magazine is a monthly. Information is available from Gwen at: 85 Fifeshire Road, Willowdale, Ontario, Canada M2L 2G9. Mention RTTY Loop when you write her, okay?

To the many readers who have written in questions and requested personal answers: By the time this is published, I should be essentially caught up. That means that if you have written me and enclosed a self-addressed stamped envelope prior to one month ago, you should have received a reply. I discovered my two wonderful kids going through Daddy's desk and "sorting mail." I don't think I've lost anything, but if you have not received a reply, it is possible.

That SASE bit is not just for me, by the way, but is common courtesy whenever you write any author whose work you enjoy and from whom you desire a personal answer. That should go for not only articles you read here, but even those in (shudder) other magazines.

Next month, we will get to some of those burning questions sent in by the readership as we complete our second year of RTTY Loop. When we pick it up again, in June, we will add the second half of the program covered last year, sending RTTY with a microcomputer. Again, while the program will be written for one specific microprocessor, I hope to present it well enough so that it may be adapted to other popular systems.

Microcomputer Interfacing

David G. Larsen
Peter R. Rony
Jonathan A. Titus
Christopher A. Titus

DATA ACQUISITION

The software in the previous column provided an example of a program used to acquire a single analog point in digital form. We are generally interested in applications in which a series of points are to be acquired, stored, displayed, and perhaps manipulated. This month's column will explore the use of microcomputers for data acquisition.

In our discussion of microcomputer-assisted data acquisition, we shall assume that the analog-to-digital converter (ADC) is interfaced as shown in the previous column. The software, which is repeated in Table 1, is also assumed to be the same. The digital value of the analog voltage is returned in the B and C registers (register pair B).

In most data acquisition programs, a fixed number of points are to be acquired over a fixed period of time. In our example, 100 points will be taken, one every second. The 100 data points will be stored in read/write memory so that they may be used later. In writing data acquisition software, we are now faced with three tasks which must be performed in addition to the actual ADC task: 1) provide a software counter to count 100 points; 2) provide a one-second timer; and 3) provide software to store the data values.

The software necessary to count the 100 acquired points will actually count 100 passes through the data acquisition software. A general-purpose register within the 8080 chip is well suited for this; conditional jump instructions may be used to detect when the count is decremented to zero. The counter may be either incremented or decremented, but decrementing is probably easiest to use if you are just starting to program microcomputers. Storing the data in memory is not difficult. Once the converter value is stored in a register pair, the H and L registers (register pair H) may be used as memory pointers to point to a R/W memory location. Note that a complete 16-bit address must be specified for the MOV M,r instructions. Since the data is acquired from a 10-bit ADC, two successive memory locations must be used to store each *point*. The INXH instruction (increment register pair H) provides an easy means of pointing to the next successive memory location. We will store the data by placing the eight least significant bits in location n and the two most significant bits in location n + 1.

The one-second timer may present some problems, depending upon the type of system which will be used. It is relatively easy to write a one-second software delay program using a series of register-decrementing loops, nested one within the other. However, this means that to accurately time a one-second period, the computer must be doing nothing else. In a system which is dedicated to data acquisition for the 100-second period, such a procedure is valid. If interrupts occur or if the computer cannot be allowed to "do nothing" most of the time, an alternate solution is needed. One possibility is to use an external clock, often called a *real-time clock*. Real-time clocks are unaffected by computer execution times, interrupts, slow I/O devices, etc. Once started, they will continue to run at an accurate rate until they have timed the particular period of interest and sent an in-

New Products

HAL'S NEW DS3100 ASR

HAL Communications Corporation has announced a new electronic RTTY terminal—the DS3100 ASR. The new terminal features full buffering of both received and transmitted data, thus permitting preparation of transmit text while receiving, as well as storage of up to 150 lines of received text and 50 lines of text to be transmitted. The new terminal also features a new screen format with 24 72-character lines split to show both receive and transmit buffers, line numbering for each buffer area, on-screen status indicators to show terminal code, rate, mode, etc., and a new high-contrast green P31 phosphor screen for easier viewing. The screen also uses bright/dim intensity changes to differentiate between keyboard and received data. A total of 10 HERE IS programmable identifier messages are available, two of which can be saved even while power is removed from the terminal. An IDENT feature allows Morse identification regardless of the terminal's selected data code.

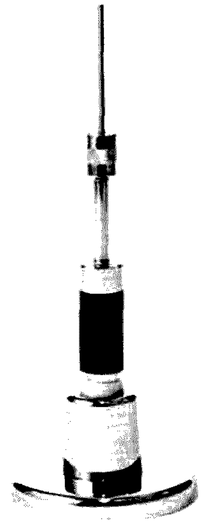
Other features include a real-time clock, programmable answer-back (WRU), upper- and lowercase ASCII, ASCII speeds from 110 to 9600 baud, four keyboard-operated output switches to control accessories, and a full 25-pin modem connector for ASCII computer connections. As did the previous DS3000 KSR V3 terminal, the new DS3100 ASR will send and receive all three data modes (ASCII, Baudot, and Morse), allows use of continuous, line, or word transmitting modes, and has synchronous idle, unshift on space, and word wrap-around. Both the electrical and mechanical features of the terminal have been completely redesigned to use a Z80 microprocessor and plug-in circuit boards, and to allow easy service. A front-face legend has been added to the keytops to fully label all control functions of the terminal and simplify operation. The keyboard and new streamlined cabinet are color-coordinated in a new two-tone castle tan and chocolate brown finish.

The terminal weighs 45 pounds and can be connected for use with 120 or 240 V ac, 50- or 60-Hz power mains. The cost is $1995.00, including shipping within the United States; deliveries of the first units will start before May 1, 1979. For further information, contact *HAL Communications Corporation, Box 365, Urbana IL 61801; (217)-367-7373.*

HAL's DS3100 ASR electronic RTTY terminal.

NEW CUSHCRAFT ANTENNAS

Cushcraft has introduced two new high-performance VHF/UHF mobile antennas. They feature 3-dB gain with 5/8-wavelength stainless steel whips and precise frequency adjustment with a fingertip collet. There are trunk-lip and magnetic-mount models which have been tested to speeds in excess of 90 mph. The antenna packages include 18' of RG-58/U cable with connectors, plus car-finish protective pads. The VHF models cover 144-174 MHz, including the 2 meter FM subband. The UHF model covers 220-225 MHz. For further information, write to *Cushcraft Corporation, PO Box 4680, Manchester NH 03108.* Reader Service number C67.



One of Cushcraft's new mobile antennas.

COMPUTER-GENERATED BEARING CHARTS

How accurately are you pointing your beam? Until recently, I thought I was doing a pretty good job of pointing mine. Oh, sure, I was using one of those standard charts centered on the nearest big city (Boston in my case), but I always figured that was close enough. Now I've changed my mind, thanks to the superb selection of beam heading charts offered by Bill Johnston N5KR.

For more than a dozen years, Bill has been supplying hams with the real McCoy: Great Circle bearing charts centered on the exact QTH you specify. No more guesswork... no more trying to make do with a chart centered hundreds of miles from your QTH. The amazing thing is that Bill can send you his basic chart for just $1.00. What do you get for a buck? The basic chart gives you beam headings from your QTH to 660 cities, countries, and islands around the world. The listings are evenly split between DX and domestic locations. The chart also shows the distance to the other QTH in both miles and kilometers, as well as the beam heading the other fellow should be using to maximize his signal to you. All this for $1.00!

I compared Bill Johnston's $1.00 chart to another I'd seen advertised for $4.95. The $4.95 chart was the loser by a wide margin. It listed only 332 different locations, and if you don't live near one of 51 American population centers, you're out of luck, because the charts are not customized to your QTH.

Bill Johnston has recently expanded his offerings, which now include enlarged DX and US beam heading charts, OSCAR/RS acquisition charts, geosynchronous satellite pointing charts, computer-generated code-practice groups, and even a computer-drawn Great Circle map centered on your QTH. All are reasonably priced. *Bill Johnston N5KR, 1808 Pomona Drive, Las Cruces NM 88001.*

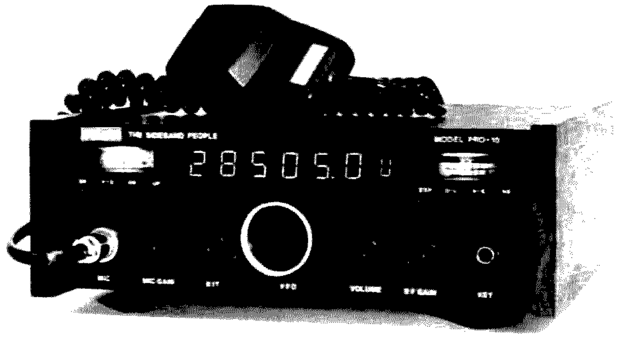
THE DIAL SPOTTER

At last, we hams and shortwave listeners have a digital product which puts new useful life into our old general coverage receivers and makes logging a snap. The Dial Spotter by Gemini Instruments enables you to quickly and easily read frequency within 1 kHz from 1 kHz to 35,000 kHz. The beautiful part about this instrument is that it adapts to any 455 kHz receiver whether it has a plus or minus or both offsets on the high frequency oscillator. My DX 160 receiver has a minus offset on the lower frequencies and a plus offset on the 13-to-30 MHz range. To change offsets on the Spotter, you simply throw an external switch which gives you additive or subtractive mixing.

The installation of the unit is quite simple. The Dial Spotter comes with an ac power supply and simply plugs in. The most difficult job is taking your receiver out of its cabinet so that you can add a simple connection. You don't butcher your receiver in any way, but just add a condenser lead out to a phono jack. The Dial Spotter comes with either 110 ac or batteries. The appearance is excellent. The readouts show up brilliantly in light and are large enough so that you do not have to squint to read them. After several weeks of use, I am delighted with its performance. There is stability in the readout, with little or no roll, and it beautifully follows your tuning.

If you are looking for a digital

The Dial Spotter.



Stoner's Model PRO-10.

readout to update your receiver, this is it. Shortwave listening becomes a pleasure, since you can quickly go back to a station or find a new station. The unit has an internal switching system which enables you to correct for a difference in i-f frequency of plus or minus 4 kHz. Thus, if your i-f is off a little from 455 kHz, you can make corrections after installation. Calibration is simple, as all you have to do is tune in a WWV or local broadcast station and adjust the switches. The calibration holds permanently.

The Dial Spotter is not a totally new design. It has been used in a slightly different configuration as the Navigator Mate, which is used by boaters for frequency readout on their portable RDF/ADF receivers. The unit weighs 6 lbs., measures 10½" x 2½" x 11", and comes with ac, 4- or 5-digit readout, black anodized finish, and several options. Also included is an excellent instruction manual.

For further information, write the *Gemini Instrument Co., Box 205, Larchmont NY 10538.* Reader Service number G27.

FIRST HAM RADIO WITH AMPLITUDE-COMPANDORED SPEECH

Stoner has just introduced the first amateur radio transceiver to employ amplitude-compandored speech. Officially called the Model PRO-10, it has been dubbed "The Black Widow" by those who have seen and heard it operating on the 10 meter band.

The impressive performance of the radio is the result of a tiny integrated circuit from Signetics. The "chip" contains the equivalent of a six-foot rack of tube-type telephone-circuit speech-processing equipment.

Amplitude compandoring involves logarithmic speech compression and expansion with no audible distortion. Part of the IC compresses the speech to raise the average modulation and "talk power." The other half of the Signetics "chip" is used to expand the voice on receive. The company stresses that both the incoming and outgoing signal are enhanced significantly even when the PRO-10 communicates with conventional SSB radios. A technical paper on amplitude-compandored speech is available from STONER upon request.

The PRO-10 is described by the company as a "platform" for high-technology SSB concepts. It operates on 10 meters. The SSB/AM/CW transmitter features 100 Watts minimum power output over the entire band. The receiver has a sensitivity of 0.5 microvolts for a 15 dB (S + N)/N ratio. A built-in six-digit frequency counter, which reads ± 100 Hz, features jumbo 0.5"-high LEDs.

The PRO-10 also features state-of-the-art electronic tuning (fast or slow) from either the panel or the microphone. A PLL (phase locked loop) tunes the radio in 10-kHz steps, while a vfo provides continuous tuning (1 kHz per turn) between steps. A built-in memory stores the last frequency used when the radio is turned off. Break-in CW operation is provided by carrier offset (50 Watts power output).

Another feature of the PRO-10 is the inclusion of amplitude modulation (AM). Noting the popularity of converted CB radios on 10 meters, Stoner incorporated a provision for this mode by employing a dual-bandwidth (2.5- and 5.0-kHz) crystal filter. The carrier output is 25 Watts. The operating mode (U, L, or A) is indicated by an LED to the right of the frequency display.

The PRO-10 measures 9" W, 8" D, and 3.25" H, an ideal mobile configuration. The power required is 13.6 V dc at 5 Amperes average current. *Stoner—The Sideband People, John Hancock Building, Mercer Island WA 98040; (206)-232-9464.* Reader Service number S85.

NEW "BEARCAT® 211" SCANNER HAS 18 PROGRAMMABLE CHANNELS

A new, crystal-less scanner radio with 18 channels which can be programmed with push-button ease has been announced by Electra Company. Named the "Bearcat 211," the new radio also features direct channel access which allows the user to manually select channels directly, without the need to step through other channels. In the radio's automatic scan mode, the 18 channels can be scanned at either 5 or 15 channels per second, permitting closer monitoring of desired frequencies. Also included is a patented selective scan delay which permits a 2-second delay to be programmed for any channel, allowing reply calls on the same channel to be picked up.

The new Bearcat 211 scanner radio also features a built-in digital clock function utilizing the radio's bright-red LED digital display. The high accuracy clock shows hours, minutes, and seconds. Another feature built into the new radio is automatic squelch. This feature allows the convenience of selecting a factory pre-tuned squelch level eliminating the need for manual squelch-level adjustment.

Thousands of frequencies in six bands are covered by the new Bearcat 211. Included are public safety, marine, government, transportation, and amateur communications. In the radio's "search" mode, the radio will seek out active frequencies between the limits selected by the user. Electra Company's patented Track Tuning is used to provide optimum reception across wide frequency bands. Complete details on the new Bearcat 211 scanner are available from Bearcat scanner suppliers or by writing to *Electra Company, PO Box 29243, Cumberland IN 46229.* Reader Service number E40.

Contests

from page 14

is the only indication of amateur interest the Bermuda Dept. of Tourism has.

COUNTY HUNTERS SSB CONTEST
Contest Periods:
0001 GMT Saturday, April 21 to 0800 GMT Saturday, April 21
1200 GMT Saturday, April 21 to 0800 GMT Sunday, April 22
1200 GMT Sunday, April 22 to 2400 GMT Sunday, April 22

Please note the two four-hour rest periods!

This is the 8th annual contest sponsored by the Mobile Amateur Radio Awards Club, Inc. Mobile stations may be worked each time they change counties or bands, but, if worked again from the same county on a different band, count for point credit only. Mobile stations contacted on a county line count as one contact but two multipliers. Portable stations will be considered *fixed* stations. Fixed stations may be worked by other fixed stations only once during the contest regardless of bands. Repeat contacts between fixed stations on other bands are not permitted! Fixed stations may be worked by mobile stations each time they change counties or bands. Repeat contacts between mobile stations are permitted provided they are on a different band or in a different county.

EXCHANGE:

Signal report, county, and state (country for DX). Mixed mode contacts are permitted provided that one station is on SSB. (Mobiles, please keep an ear for CW county hunters calling!)

FREQUENCIES:

3920-3940, 7220-7240, 14275-14295, 21375-21395, 28575-28595. Look for mobiles on 15 meters on even numbered hours.

Please note: Again, this year there will be a "mobile window" of 10 kHz on the following frequencies: 3925-35, 7225-35, 14280-90. Mobiles will be in this 10-kHz segment and fixed stations are asked to refrain from calling "CQ Contest" in this segment. After working mobile stations in the "window," fixed stations are requested to tune and work other mobile stations or QSY to the outer edges of the suggested frequencies to call CQ or work other fixed stations in the contest. This will allow the mobile running lower power a chance to be heard and worked in the contest.

SCORING:

Contact with a fixed/portable US or Canadian station = 1 point. Contact with DX stations (including KL7 & KH6) = 5 points. Contact with mobile stations = 10 points. Multiplier is total number of US counties plus Canadian stations worked; take credit for a county only the first time it is worked. A Canadian station counts each time it is worked. Final score is total number of QSO points times total number of different counties and VE stations worked.

ENTRIES:

Logs should show date/time in GMT, station worked, report exchanged, county, state, band, claimed points (1, 5, or 10), and each new multiplier numbered. Official log sheets and summary sheets are free for a #10 SASE or SAE and appropriate IRCs from John Ferguson WØQWS, 3820 Stonewall Ct., Independence MO 64055. Submit all entries to the same address no later than June 1 to be eligible for awards; DX should use air mail.

AWARDS:

Plaques to highest scoring fixed US or VE, DX, mobile, and 2nd mobile; certificates to top 10 fixed and mobile stations in US and VE and to the highest scoring DX in each country. Only single-operator stations are eligible for these awards, but multi-op certificates may be issued if merited. A station may enter as both fixed and mobile, but separate scores are required.

WORKED ALL SOUTH EAST AWARD (WASE)

This award is offered by the Southeast Amateur Radio Club of Cleveland OH. An attractive certificate is available to all amateur radio operators who QSO with at least three members of the club on any band below six meters. Members of the club will be on 14.30 MHz every Wednesday evening starting at 0130 GMT. The club also meets on 28.70 MHz at 0130 GMT each Sunday evening for its weekly club net. To get your WASE certificate, send an SASE along with the callsigns of three club members and the date of each QSO to: WASE, c/o WD8KIS, 2196 South Overlook Road, Cleveland Heights OH 44106.

Looking West

from page 8

amateur band had little to no activity to speak of, depending upon where you lived. Remember that it's been but two short years since 220 started to come into its own—as a result of two happenings.

Happening one was the severe overcrowded conditions which developed on the two meter band in localities such as southern California, New York, metro Chicago, and a few others. Amateurs wanted to get away from these conditions and started to look elsewhere. Many migrated to 450, but in some places, especially southern California, that band, too, was very crowded. Starting first in southern California, amateurs began to look at 220 as an alternative.

This was the spur to the second happening. Recognizing that amateurs were giving 220 notice, a number of manufacturers began to produce equipment for the band which was popularly-priced. Just as Heath was credited with "making" six meters years ago, companies such as Midland, Clegg, Wilson, and Cobra will go down in the amateur annals as the pioneers of 220.

By the time the 220 Class E proposal came to fruition, amateur operation had begun to entrench itself on that band. And by the time the FCC announced that the proposal was no longer viable, we had run out of 220 repeater pairs in southern California. Even if the proposal had gone through, it would have been all but impossible to implement here.

There was one fly in the ointment, though. 220 CB might have been approved had not our neighbors taken issue with the idea. They had witnessed the 27-MHz mess and did not want an expanded version of it. Maybe, had the US been able to guarantee that it would have been a totally-structured, heavily-policed service, it could have passed, but even the most bureaucratic of bureaucrats would have thought twice about that one. So, much to the dismay of many manufacturers who had hoped that 220 would be a needed shot in the arm for the teetering CB industry, 220 Class E died. If the ARRL had said nary a word, or even if they had supported the idea, it probably would have died the same death.

There is a difference between the Class E CB proposal and the current US WARC proposal pushing maritime mobile. Unlike CB, maritime will be looked at as a structured and policed service. Moreover, this is not a proposal for a given nation, but rather for the entire world. Now, when you "lose one," as happened with Class E CB, you do not go out to get egg on your face again. The FCC "lost" in the Class E fiasco, so they are not about to take that chance again unless they thought they had a viable proposal. This means that they would at least expect support from throughout the region. I believe that the ARRL will be looked upon as no more than a radio club—unable to take on an entire region. They are just not that powerful. It would be nice if they were, but such is not the case. If they had taken the initiative years back and invested in a professional lobbyist rather than a new office building, they might have developed the necessary structure to fight such transgressions as these. In fact, had the ARRL developed an effective lobby in Washington, we would not now be facing crisis after crisis.

There is another important factor. The ARRL just does not have the overall support of our VHF community. The world of VHF communication is fascinating and fast-moving—especially that of VHF/UHF relay technology. Yet the ARRL has always been slow to react to the needs of that segment of the amateur society. In most cases, they have acted "after the fact." I seem to remember that half of the national number of repeaters had been coordinated along a 2 meter band plan before the ARRL got around to endorsing one. What is called the ARRL Band Plan for "2" is, in actuality, the Modified Texas Plan. Later, after the ARRL recognized that inverted tertiaries worked better than right-side-up ones, the Southern California Band Plan suddenly became incorporated in the ARRL one. Another recent ARRL acquisition has been the band plan for the 144.5-145.5-MHz subband. This is actually the NARC or Northern Amateur Relay Council Band Plan; it was not dreamed up by the ARRL. There is nothing original in the ARRL 2 Meter Band Plan. It consists only of what they have borrowed from others and attached their almighty name to.

If the ARRL were the true VHF/UHF leaders, they would have developed band plans for all spectral activity long before they were necessary. They didn't, and to date they have not come up with anything

original. They borrow and endorse but they fail to create. Part of the job of a leader is to be imaginative enough to plan ahead. They have not, and because of this, they cannot gain the support of the majority of the VHF/UHF community.

Another graphic example of the lack of leadership is the League's reluctance to enter into the realm of total spectrum management. This is a concept that the League should have pioneered. Instead, the idea developed from a single small regional repeater council, the SCRA. In fact, the SCRA (under its new title, 2mASMA) evaluated, modified, accepted, and implemented the recommendations of the ARRL's VHF/UHF Advisory Committee's proposed national 2 meter bandplan while the ARRL's Board of Directors debated its merits. It's a good plan, and with only one slight modification, it truly serves the needs of all 2 meter users. This plan should have been implemented nationally a long time ago, yet we still await Newington's decision. Southern California elected not to wait. Other areas, including the Southeast, seem to be reaching the same conclusion and are proceeding without Newington's okay.

All this comes down to the fact that the ARRL is not being effective enough as a VHF/UHF leader. And without support from the VHF/UHF masses, there is no way for them to obtain the stature necessary to dissuade the rest of the region and possibly the world from doing anything they want. 220 marine is just another example of this—and it may be the straw to break the VHF world's back. Those whom I have spoken with want no part of the ARRL in the fight to save 220. They feel more secure in going it alone than they do with the quasi-support of the ARRL. If the amateurs are able to fight off this latest threat to 220, the ARRL will again probably try to steal the spotlight. If 220 is lost, it will also mean an end to *any* support for the ARRL by those involved in VHF/UHF relay communication—and that's a big chunk of the amateur population.

HOW CAN THIS BE CHANGED?

There are two organs within the ARRL which could become the VHF/UHF leaders of tomorrow if the ARRL Board of Directors would let them. They are the VHF Repeater Advisory Committee and the VHF/UHF Advisory Committee. However, they both seem continually stifled by the bureaucratic attitudes of the ARRL Board of Directors. Eventually, because of this lack of Board initiative, some of those who have served on the VRAC have felt that they have had enough and have left. Can you blame them? Put yourself in the position of being an advisor to their Board on matters with which the Board was a bit unfamiliar. You were selected because of your knowledge of VHF/UHF communication and were told to advise the Board on such matters. The committee itself exists because the Board knows little about the topic. If they were experts on it, why would they have the advisory committee in the first place: By forming such committees, the ARRL Board admits its knowledge deficit in such areas.

So, you research something. Let's say it's a band plan for six meters. You present it to your fellow committee members and they agree. Your chairman then forwards this committee recommendation to the Board, where it is formally pigeonholed. Eventually you give up and do one of two things. You protest and quit, or you become a good little boy and enjoy your status as a committee member while doing as little as you can. Frankly, I can't blame anyone who does either under the current scheme of things. However, there is so much potential in both the VRAC and the VUAC that it's a shame to see all this talent wasted. It *can* be changed, and here is one way:

First, both the VRAC and the VUAC have to be taken out from under the Board of Directors' thumb. Members of both committees should not be appointed through Newington, but rather should be elected on a Division basis as are Division Directors. It would then be the people rather than the bureaucrats speaking. Within this elected body, another election should be held to determine a chairman and a liaison officer. Decisions of such committees should then be presented to the ARRL membership and voted upon by the members as to whether such should or should not be implemented. The Board should keep its nose out of it, since by creating such committees, they admit that they are not at all adept at these matters in the first place. Once the roadblock caused by the Board of Directors is eliminated, the VRAC, the VUAC, and other expert League committees can go forth and help guide amateur radio directly.

The big question is: "Can it ever happen?" It's a simple, effective idea, but one that would dilute the Board of Directors' authority. I doubt that the current regime in Newington would buy it. Therefore, the real answer is a long-term one. It means voting into power individuals whose views are the same as yours. It means evolutionary change, and, unfortunately, we in VHF/UHF just don't seem to have the time to await such a happening.

As in the past, things keep going with or without the ARRL. They will continue to take credit for what we accomplish and we will keep on accomplishing with or without them. If we survive WARC, VHF and UHF will continue to grow and prosper. New ideas will continue to pour forth. If the ARRL announced today that it was pulling out of any further involvement in this part of amateur radio, it would not matter one iota. That's what makes the whole thing so sad.

COORDINATION: THE BEST METHOD YET

Gary Pearce WA9NSO is the Illinois Repeater Council's coordinator. Over the years, I have heard quite a bit about Gary, but it was not until recently that I had the pleasure of meeting him and finding out first-hand how the IRC faced an almost overwhelming problem and was able to conquer it. Here is the story, as Gary explained it to me over lunch in San Diego.

About a year ago, the IRC simply ran out of places on two to put repeaters. There were always far more requests for spectrum than there was space available. Eventually there was no more, even with co-channeling and similar measures. At this point, the idea was born in the IRC that it was time that it became an advisory rather than an administrative group. A new concept of repeater coordination took root, which I will term "advise and consent coordination."

According to Gary, someone coming to the IRC these days for a metro-area repeater on two does not get an exact assignment. Rather, he is given an accurate listing of all area activity and told to go forth and find himself a home which will cause minimal interference to himself and all existing activity. The rationale is that nobody wants to be interfered with, and thus the new repeater owner will seek a home which satisfies this criterion. This concept takes the responsibility for minimizing and/or eliminating interference and places it squarely upon the shoulders of the new system owner. In such cases, the IRC operates on an advisory level. If all goes well, it gives final consent to the system's establishment and operation.

After listening to Gary, I took the initiative and developed a similar plan for this area, which I presented to the 2mASMA Technical Committee. The Committee decided to give it a try. Some new forms to utilize the concept were developed and included in the coordination information packet which is sent to every new repeater applicant. The results have been amazing.

2mASMA administers a very large area, one of the largest in the nation. It is impossible for a committee meeting in LA to know every bit of spectral activity in this geographic area. At least half a dozen coordinations have been made using this system to date, and not one has come back to haunt us. In the past, at least two out of every six have—especially from the overcrowded LA-San Diego rf corridor which for years has been the crux of our problem. It's no longer simply a matter of requesting a channel pair. You must go out and find one upon which you can survive—and in this no-man's-land, that's not that easy. The burden for technical excellence is now on the amateur, rather than on the council committee, and that should eventually lead to better technical excellence on the air. For coordinators and/or coordination committees interested, an SASE to PO Box 2606, Culver City CA 90230 will bring a sample copy of the aforementioned self-coordination forms, which 2mASMA will gladly let you duplicate for your own use.

GROWING PAINS DEPARTMENT

One organization which has had its share of growing pains and is now emerging to a position of leadership in the world of hobby-service two-way radio is a group called H. F. International, with headquarters in Riverside CA.

Once regarded as a renegade CB club which promoted illegal, out-of-band, and overpower operation in the spectrum between the 11 meter CB and 10 meter amateur bands, HFI, now under new leadership, has emerged as an organization dedicated to serving the needs of the hobbyist SSB enthusiast, be he CBer or ham. There is a lot more to HFI than meets the eye, and now, and in the future, I hope to give you a bit of insight into that organization and the changes which have occurred within it.

I know that some of you will take issue with my devoting space in an amateur magazine to something not purely amateur- or VHF-oriented. Others may take the view that all HFers are nothing but illegal radio operators and must not be given recognition. Neither of these statements holds much water. There is one important

reason why you should know about HFI and its people: Many of them are transitionites, in the process of leaving CB and becoming amateurs. One of the avowed new goals of HFI is to educate the CBer of today so that he/she can be the good amateur of tomorrow. Then, too, 100,000-plus hobby radio operators make up a big chunk of today's personal communicators and, just as the US could no longer fail to recognize the existence of mainland China, we in radio cannot bury our heads in the hope that HFers will all just go away. The fact is that what is termed illegal radio operation between channel 40 CB and the low end of 10 meters is growing at a phenomenal rate; another goal of the new HFI is to try to curtail this.

Like most other amateurs, for years I have been very boisterous in expressing my indignation at any illegal operation. A year ago, if you had asked me who all those bad guys were, I would have said that they were all members of HFI. The fact is that I said that many times and to many people. One day I said it to another amateur, who simply giggled a bit. He called me back later to offer LW a chance to meet with the president of HFI and judge for myself. The meeting was arranged according to certain ground rules I set down. I was still feeling indignant. There were two things. First, it would have to be a no-holds-barred interview, in which I could ask anything I darn well pleased. The second condition was that I be permitted to tape-record the interview so that later on no one could deny that what was printed had been said. This was agreed to, and early last spring I drove to Riverside and met with Norm Muller and his wife Jeannie at their home (which also serves as HFI headquarters).

We spent a rather enjoyable afternoon just "rapping" with one another, breaking now and then to change a tape or get another can of cola. I had come with the typical "ham with a chip on his shoulder" attitude well entrenched, and I was ready to do battle. The war never developed. There was an instant rapport, and it turned out to be one of the most educational afternoons I have ever spent. More in future columns.

THE JOE MERDLER REVISITED DEPARTMENT

On Tuesday, January 9th, I received the following news release from Joe Merdler N6AHU: "On January 9th, 1979, Scott Lookholder WB6LHB pled guilty to three counts of violating section 1464 of Title 18, using obscene and abusive language as a misdemeanor. Maximum penalties are up to 1 (one) year in prison and up to a $5,000 fine on each count. Sentencing is set for February 6th, 1979."

Looking West will have more on this in the future. However, we do have a rather interesting sidelight to report now. As a result of running the text of Joe's San Diego speech last December, he has been reunited with a relative he never knew existed. Joe tells the story this way:

He was in QSO on 20 meters with AA6A discussing DX when a breaker was heard. The breaking station turned out to be K8AQA in Saginaw, Michigan. K8AQA asked N6AHU: "Would you believe my name is Merdler, too?" It turned out to be Robert Merdler, and, in the course of the QSO, the two realized that they were indeed cousins. On that happy note, we will end this month's Looking West.

CARF

Canadian Amateur Radio Federation, Inc.

The DOC has announced the following changes to agreements with other countries: Add Mexico to the third-party traffic list. Negotiations are under way for third-party agreements with Australia, Haiti, Jamaica, and Liberia.

Reciprocal licensing arrangements have been made with Austria, Barbados, Bermuda, Costa Rica, Honduras, India, Indonesia, New Zealand, the Philippines, Sweden, and the United Kingdom.

On the banned countries list, the Viet Nam exceptions XV5AA, XV5AB, and XV5AC have been eliminated.

The DOC is negotiating reciprocal licensing arrangements with Haiti, Italy, Liberia, and Spain.

Lists in copies of the CARF publication, *The Canadian Amateur*, should be amended to conform.

DX

from page 18

recommended operating habits. I keep a sked with Doug every Sunday he is available on 28031 kHz at 2000Z. When he has the time, Doug will hang around and work a few stations after our sked. Doug's general operating times are from 0500Z to 0800Z, on all bands 10 through 160. I have handled all QSLs since June 1, 1978. Prior contacts should go to K2BT. There was a very active pirate using Doug's call, so unfortunately some cards are being bounced back. Best 73, Greg WB4PRU."

Palmyra Island

This summer, one of the better-heeled newcomers to the DX fraternity plans to depart from California for a four-month tour aboard his yacht *Wildfire*. Planned stops are Hilo, Palmyra, and Christmas Island. He is definitely planning the Palmyra stop, and says if the weather permits, he will take a swing by Kingman Reef. This looks to be mainly a CW-type operation, since the operator is new to ham radio and has a CW background from the Navy. He is planning to devote much of his operating time to the Novice bands.

Chad TT8

F6FFQ is in Chad and has been signing /TT8 in the 14105 area. It is hoped that he can soon be persuaded to brave the storms above 14200.

Djibouti J28AY

WB4ENI passes along the following information on J28AY: Marc plans to QRT sometime in July of 1979, when he will return to France as F6ETO. Beginning in July, all cards should be sent to F6ETO's CBA. In the meantime, they can still be sent to the Djibouti CBA. Marc prefers CW because his English is somewhat fragmentary. Look for him on 10, 15, and 20.

Korea HL9TG

Gary writes that he will be in Korea until January, 1980, and plans to be active on SSB and CW, 6 through 80. Contacts after March, 1974, go to WA7NTF, 6419 158th Street CT East, Puyallup WA 98371 or directly to Gary Kohtala, USAFS-K Box 194, APO San Francisco 96271.

Afghanistan/Pakistan

OZ1CRH will be traveling to Afghanistan and Pakistan and is optimistic about receiving YA operating permission. He will be in Pakistan from March 15th to May 30th and plans to sign AP2LJ. QSL to WA8AJG.

Spratly 1S1B

The late word had the group departing Brunei on March 28th and landing March 30th. The plan is to operate until more than 30,000 QSOs have been logged. VK2BKL and ZL1ADI from the Mellish operation will be along, and the boat will be the same one used at Mellish.

Dodecanese Islands SV

Those needing the Dodecanese should be interested in the following letter from SV1IG in Athens:

"Please inform the readers of *73 Magazine* that I and my wife will be touring the Dodecanese Islands from July 1st to August 15th. There will be many difficulties, as not all the islands have transportation. Since some are without roads, we will not have a car either. We will operate all bands, but will concentrate on twenty meters at 14205 and 14285 kHz. QSL to Anastasios Panos, 4-6 Voltairou Street, Athens 411, Greece."

SV1IG also noted that he no longer holds office in RAAG at the awards department, so letters addressed to PO Box 564 in Athens will no longer be answered. Anastasios also mentioned possible SY Mt. Athos activity in 1980.

China

Rumor has it that at least two American amateurs have applied and received preliminary approval for operation inside The People's Republic. It has long been felt by some that the first legitimate operation from China would be by Chinese nationals, but who can tell? Work 'em if you hear 'em, and worry later.

Comoros D68AD

As an accommodation to those working toward 5BDXCC, Robin maintains regular skeds on 1804 kHz from 0230Z and on 3504 kHz from 0300Z.

Sao Tomé S9

Angelo D4CBS will have been on Sao Tomé for an extended visit which began in March. Although he holds a license and will be taking his rig with him, informal inquiries as to the status of amateur radio have

gone unanswered. Hopefully, by now you will be hearing Angelo from S9.

Pitcairn Island VR6

Things should pick up from Pitcairn on April 19th, when the *Yankee Trader* puts in on its latest around-the-world journey. Aboard will be K5UC, N1DX, and K0BJ, who has been issued the call VR6BJ. The idea will be to put VR6 on bands and modes not usually available. Planned are RTTY, CW, 40, and 80. Other RTTY stops will be CE0Z, 3D2, KH8 (KS6), and 8O6. W0PAH will handle QSLs.

NOVICE CORNER

Although in the early stages of working DXCC it shouldn't be necessary to make schedules in order to work a new one, there may be instances when you want to ensure a contact with a certain station.

The best way to do this is to write to the station's QSL manager requesting possible schedule times and frequencies. Most QSL managers keep regular schedules with the stations they represent in order to pass logs or verify contacts. Often, the DX station will either show up early or else hang around afterward and hand out a few reports.

Remember, these QSL managers have plenty of work just keeping up with the QSL demand, so be sure to include an SASE with any correspondence. It never hurts to include paper as well. When schedule time comes, just let the QSL manager know you are on frequency and then stand by until all traffic has been passed. Then you can make a contact and the QSL manager will already have you in the log.

Just remember to be patient and follow instructions, and you'll usually be able to add a new one to your log.

HEARD ON THE BAND

4S7EA runs a Tuesday, Thursday, Sunday sked for the deserving DXer on 14247 kHz at 2330Z, with K9VAL as MC.

TR8AC is shooting for 2,000 QSOs per month with those deserving DXers in need of a TR8 contact. Look for him around 14222 after 2000Z.

Those new 8L2 prefixes are the old VP2L St. Lucia stations signing their newly-gained independence-type calls.

There are still two active operators on Johnston Island. KH3AA, the chief electronics technician for the installation there, is on generally once a week, and KJ6BJ can often be found around 14056 kHz from 0600Z. WH3AAA is reported to also be on the island and trying to upgrade.

The New Jersey DX Club has been supplying some needed manpower in an effort to reduce the QSL backlog at 4U1UN. They are having some success, but it never seems to be enough when you are among those in the waiting line.

Congratulations to new ARRL DX Advisory Committee members K5YY, K7LAY, and W0SR. They join holdovers W2XN, N6RJ, WB8EUN, K9AM, W3ZN, N4MM, and Chairman W1OT. Any complaints or bouquets you have concerning DX should be directed to these deserving ones.

Box 88 is slow but sure. K4IIF, who handles the *CQ Magazine* awards program, recently received six pounds of cards and applications from Moscow. The applications included 93 for WPX, 27 for CQ-DX, and 17 for WAZ. The round trip for these applications from Moscow averages 18 to 24 months. While we are on the subject, *CQ* recently raised the fee for the WAZ certificate from $1 to $2.

Apparently they will never run out of new countries. Look for the Marshall Islands, the Palau Islands, and Micronesia to obtain some form of independence by 1981.

Congratulations to WA8MOA, recent recipient of the first "Michigan DX Plaque," for his efforts in the Mellish Reef operation.

The FCC recently raided Brewer Labs in Porter, Oklahoma, and seized some 440 illegal CB linears valued at $200,000. According to a story released by the AP, these amplifiers cause TVI.

The January/February issue of *Oceans* magazine has an interesting article on Canton Island, the Auckland Islands, and Palau. Check your library for a copy.

W6KPC just put up a 12-element 20 meter beam on top of a Sky Needle at the top of a 100' tower.

The International Island DX Net meets every Friday at 0300Z on 14280 kHz. The net is operated by the Whidbey Island DX Club. Write WB7BFK for more information.

Maurice Caplan, who gave out many a new country contact as VS5MC from Brunei, has retired from the DX wars and returned to England.

KV4KV says no Desecheo activity until the ARRL decides on its country status.

Some big bets are being made among the south Florida DXers as to who will be the first to earn 5BWAZ. The winner will be entitled to use "The Big Florida Pizza" on his QSL card.

The Delta DX Association will send a computer-derived beam-heading chart to any DX station *free* for the asking. Write to Box 73, Metairie LA 70004.

Sometimes a letter to Box 88 will shake out some long-needed cards. Two years ago, K6DT wrote complaining about some overdue QSLs for contacts back in 1972. Now, two years later, the cards have finally come through. Where Box 88 is concerned, it just takes a lot of patience and sometimes a little prodding.

Word has come through that E. R. "Robbie" Robson 5Z4ERR, formerly VQ4ERR, became a silent key during December.

Chod Harris WB2CHO is in the process of setting up a permanent contest-type QTH in Montserrat, where he holds the call VP2MAY. The station setup will include a five-element quad for 10/15/20 and a two-element quad for forty. He will have three complete operating stations. Chod was with the group which ran up 7.4 megapoints from 9L1CA in the recent CQWW DX contest. In the meantime, between contests, he plans operation from VP1, PZ, 8R, TF, HB0, 3A, and other European spots. QSLs go to WA1SQB.

China recently ended their economic aid to Albania, and there seems to be a slow shifting of the Albanian axis toward the west. This opens up future possibilities of a true ZA operation by some visiting Europeans.

Don't discard your old *Callbooks*. Many of our DX friends overseas are unable to obtain US or foreign *Callbooks*. Send your old discarded *Callbooks* to WA4JQS, and Tony will mail them overseas at his expense. He will also advise you of the recipient.

The Long Island DX Association is looking for associate editors. Contact W2IYX if you are interested in helping out and getting your own byline.

Speak of the Devil, or at least a new country, SM3VE and SM4CNN advise that they have received a license and will activate ZA5A on all bands including OSCAR and 436 MHz the last week in June and first week in July.

There is really no excuse for not having worked KV4. Dick KV4A ran off nearly 50,000 QSOs during 1978. That's better than 100 a day.

The ARRL is petitioning the FCC for Novice privileges in the 220-MHz band. They have also asked for standard FM emission in the 52.0 to 52.5 MHz band.

The February *QST* carried a feature article on "incons." These are devices which combine inductance and capacitance into one component. The ARRL is issuing a news release on these and is canvassing the House and Senate Subcommittee on Communications. The feeling is that incons are helpful in reducing RFI.

TT0KP has been showing on twenty recently. He is reported to be a police officer there in Chad. QSL to F9KP.

Total US amateur licenses as of December 1, 1978, numbered 353,162. This breaks down to 61,000 Novices, 68,000 Techs, 118,000 Generals, 82,000 Advanceds, and 22,000 Extras. The gain for November was 325, and the 12-month gain was 26,404.

Contesters will be happy to note that K8TMK has filed a petition, RM-3281, asking amendment of part 97 so that contacts of one minute or less will not require an amateur station to identify the station it has contacted. This might work against the contester, since many contest-type DX stations go several minutes without identifying themselves, and the only time you hear their call is when the US station gives it.

THE IC-280

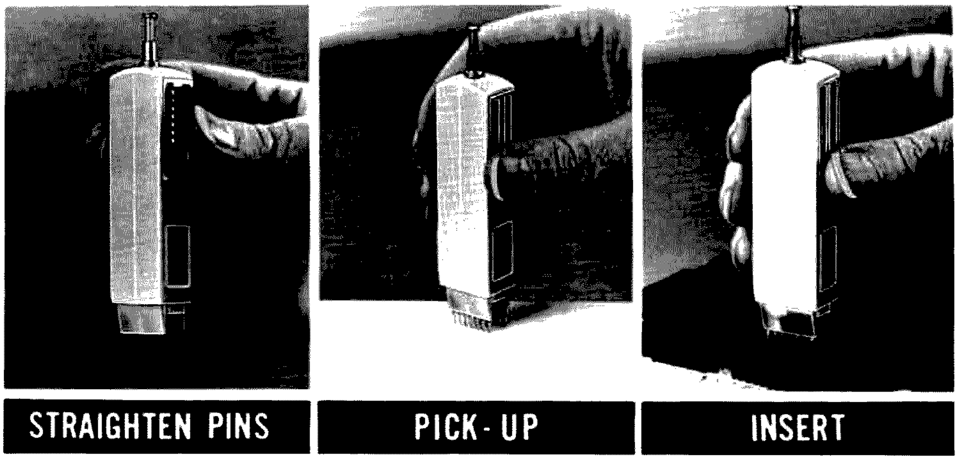
The versatility of a microprocessor is exemplified in the Icom IC-280 4 MHz + FM mobile radio for two meters. Referred to as the "remotable" radio, the IC-280 actually comes assembled for immediate operation as one box. However, the same radio may be separated by removing the head, connecting the optional remote cable to each unit, and mounting the head in a small place where almost no other radio will mount.

"Remotability" is not the only reason to have an IC-280. The microprocessor covers all 4 MHz of the two meter band, plus some at both ends in 15- or 5-kHz steps which are selected by the user or the processor. In addition, there are three memory channels which can store any frequency which can be programmed on the dial. This allows the set to act as an "eyes-on-the-road" radio for safety. The modular 10-Watt output stage has plenty of power to drive the most popular amplifiers to full output, and the continuous display of frequency in either the transmit, receive, or memory position makes the IC-280 the best FM radio Icom has come up with yet. For further information, contact *Icom East, Inc., 3331 Towerwood Dr., Dallas TX 75234*, or *Icom West, Inc., 13256 Northrup Way, Suite 3, Bellevue WA 98005*. Reader Service number I1.

Icom's IC-280.

MOS- AND CMOS-SAFE INSERTION TOOL WITH PIN STRAIGHTENER

OK's new model MOS-1416 DIP insertion tool inserts both 14- and 16-pin IC packages into sockets or predrilled boards. Total conductivity reduces static electricity. A ground strap may be easily attached for highly-sensitive MOS and CMOS ICs. Durable chrome-plated ABS construction features precision parts for long life and easy one-hand operation. The tool's narrow profile permits it to work on densely spaced patterns, while its unique insertion mechanism assures accuracy as well as excellent "feel." Finally, the tool includes a remarkable pin straightener built into the handle. Simply insert the IC, rock it on the straightening saddle, and push down on the tool. An automatic ejector delivers the IC ready to be placed in the insertion end for installation in your board or socket. The MOS-1416 is available at your local electronics distributor or directly from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475*. Reader Service number O5.



OK's new insertion tool.

HUSTLER ANNOUNCES NEW TRIBAND BEAM FIXED-STATION ANTENNA

Hustler has announced the new Model 3-TBA triband beam antenna. The amateur beam antenna covers the 10-15-20 meter bands. The longest overall element length is 23' 10", and the antenna is designed and tuned for a 24-dB front-to-back ratio. Its unique design permits the elements to be much shorter than other beams on the market today. The boom length is fourteen feet, and the antenna provides better than 8-dB gain. The 3-TBA easily handles power inputs of 1 kilowatt, and is easily matched to 50-Ohm cable.

Constructed of 100% heavy anodized aluminum with stainless steel hardware, its weight is only 36 lbs. The all-new Hi-Q trap design uses twelve-gauge aluminum wire, requires no capacitors, and, once tuned at the factory, is permanently weather-sealed for years of reliable operation. This antenna is sure to be a favorite of those operators entering DX contests.

For further information on this or other Hustler antenna products, write: Sales Department, *New-Tronics Corporation, 15800 Commerce Park Drive, Brookpark OH 44142*. Reader Service number N2.

READERS REVIEW THE WILSON MARK II HT

Have you been looking for a small, lightweight, hand-held two meter unit? I had been looking for about a year, but could not decide which brand to buy. Then, on July 4, 1978, I heard a QSO in progress on 146.52 between John Shean N9TV and Charlie Dalton WD9AGK. John said that he had bought a Wilson Mark II and had worked Indianapolis direct with it early that morning. He had climbed his tower to work Indy, which is about 100 miles north of here. I was with my family at my parents' house. Supper was finished. It was too early to light fireworks, so I broke into John's QSO on my Tempo FMH and asked if I could come to see his Mark II. Three days later, I ordered my Mark II from John AA9B, sales manager at Spectronics. It was shipped the same day. I have bought several rigs from Spectronics, and I find them to be excellent people with whom to do business.

The Mark II is small enough to carry in your shirt pocket with about half of it sticking out. It comes with crystals for 146.52 installed in channel A. It has six channels, A through F. There are separate receive and transmit crystals for each channel. Rejection of adjacent channel signals is excellent. The receive crystals must be netted along with the transmit crystals. There is a warning in the manual to avoid high rf fields, since they may cause damage to the receiver. The Mark II should not be used in close proximity to a base station antenna or closer than twenty inches from another unit. Transmission without the antenna can cause damage to the transmitter. My 25/85 repeater is here at my house running 100 Watts out, but it hasn't hurt the HT yet. My Mark II does an admirable job in this high-rf environment. The adjacent channel rejection it has is amazing, and you must do a good job of netting the receive crystals to get full performance. The Mark II uses a small 10.8-volt nicad battery pack rated at 500 mAh. The current drain is 15 mA squelched and 100 mA at full audio output. The current drain on transmit is 500 mA with 2.5 Watts out. The Mark IV draws 800 mA with 4.0 Watts out. The manual says the battery life is 8 hours with 5% transmit, 5% receive, and 90% standby duty cycle. The battery is easily replaced. The unit is housed in a Lexan case.

Looking at the manual, the only difference I see between the Mark II and the Mark IV is the driver transistor, with the Mark IV having a higher gain driver. Both units have an MRF

237 or SD 1127 output transistor. I have noticed a rise in the final amplifier temperature after several minutes of transmitting. This is normal. I have also noticed a rise in the temperature of the audio output final after several minutes at full volume, which is also to be expected. It should be possible to modify these units for switchable power output.

The accessories shown in the manual for the Mark series of HTs include a desk-type battery charger, a wall charger, a cigarette lighter-type 12 V dc charger, a speaker-mike, leather case, battery pack, and Digitran or Chomerics key pad. The Mark series uses the same kind of crystals as the other Wilson units. I put crystals from my Tempo FMH in mine with no trouble. Some of the channels I bought crystals for would not adjust to frequency properly until I changed the load capacitors to 33 pF. Caution must be used when you have the unit out of its case or else some of the small wires will come loose from the PC board. A single board houses both the transmitter and receiver, and a small auxiliary board houses some of the crystals.

The unit weighs only 16 ounces including the battery pack, and an excellent manual comes with it. It is checked out at the factory and the specifications sheet is included in the shipping box—something you don't find very often these days.

I would like to thank John AA9B for the excellent service from Spectronics, as well as N9TV for the demonstration that prompted me to buy my Mark II. Most thanks, though, go to Wilson for producing such a fine unit, the answer to my HT dreams.

How It Works

The Wilson Mark series of HTs are dual-conversion FM units with a single circuit board containing both the transmitter and receiver. An independent microphone element is installed just below the speaker. There is a connector for an external microphone. An incoming signal passes through a low-pass filter and bandpass filter to the rf amplifier, where it is amplified and passed through "selectivity elements" to the first mixer. The first oscillator uses an HC-25/U fundamental crystal with individual trimmers for netting each receive crystal. The crystal frequency is given by the equation Crystal Frequency = (Channel Frequency − 10.7)/9.

The first oscillator signal is coupled to the source lead of the first mixer, where it is mixed with the incoming rf from the rf amplifier. The output of the first mixer is tuned to the difference frequency, or 10.7 MHz. This 10.7-MHz signal goes through a monolithic crystal filter to the first i-f amplifier. "The crystal filter provides a flat-topped, extremely steep-sided selectivity curve for superior image rejection." The signal from the second oscillator running at 10.245 MHz is coupled to the second mixer, where it is heterodyned with the 10.7-MHz first i-f signal to produce the difference frequency, or 455 kHz. The 455-kHz signal goes through a ceramic filter to improve adjacent channel selectivity and spurious rejection. This 455-kHz signal is coupled through the second i-f chain which consists of four transistors followed by a limiter. The signal from the limiter is fed to the discriminator filter. The audio output of the discriminator is fed to the audio amplifiers. It has a noise-operated squelch.

The transmitter uses ten transistors and two diodes. The microphone audio is amplified, processed, and fed to the phase modulator. A deviation control is provided. Output from the oscillator is phase-modulated and multiplied in frequency by a factor of twelve. Then the signal goes through the driver to the final amplifier. The output signal is passed through a couple of filtering stages to the antenna.

Bob Miller N9RM
Louisville KY

Since I was introduced to 2 meter FM in 1968, I have wanted a Motorola HT-220 handie-talkie. Unfortunately, the price of even a used HT-220 was always out of my reach, so I made due with a variety of substitutes and eventually ended up with a battered HT-200. Now, understand that the HT-200 was a good HT in its day (1964), but it is big and heavy and limited in channel capacity (a maximum of 2). What had always attracted me to the HT-220 was its small size, light weight, and *professional* appearance.

Wilson Comes Through

Over the years, I have watched as various companies have introduced their versions of 2 meter HTs. I have found that none of them even came close to duplicating the HT-220. Sure, they had the technical performance, but they were as big as my HT-200 and just didn't look like I thought they should. Then it happened. Wilson ran their first ad for their Mark II and Mark IV mini HTs. They sure looked like an HT-220, and that price! $219.95. How could they sell it for that? Being the skeptic that I am, I figured that the ad was the typical case of marketing being a year ahead of engineering and that if Wilson ever delivered, the price would probably be up by 50%. A quick call to Wilson confirmed my suspicions. They said first delivery was in "3 to 4 months." Oh, well, I promptly forgot about it—but every month those full-page ads in *73* kept reminding me that Wilson was still there. Six months later, I began to see ads from distributors selling the Mark II and Mark IV. Surprisingly, the list price had only crept up by $10.00. In October of 1978, I saw a Mark IV at a hamfest. It really existed! What's more, it looked even better than the pictures. A long conversation with its owner revealed no problems, and apparently the unit performed as advertised. That was all it took. A few phone calls and a few days later, UPS left a package at my door. It wasn't my much-coveted HT-220, but something I think is even better—a Wilson Mark II. For a $250 package deal, I got a Wilson 2.5-Watt Mark II, nicad battery pack, rubber flex antenna, ac wall charger, and crystals for 146.52 simplex.

Overall Description

The MK II is what I would consider a *personal* portable radio. It is very small—about the size of a dollar bill and 1.8" thick—and weighs only 1 lb., even with the battery pack. It easily fits into a shirt pocket, and its appearance is really impressive. It sure is a long way from the early HTs, which looked like converted CB handie-talkies.

The case is finished in an attractive dark blue-grey textured style and apparently is pretty rugged, since mine has already survived a 5-foot drop onto a concrete floor. Inside the case is a real technical performer. Six channels are available on transmit and receive, and the performance leaves nothing to be desired. I've done extensive lab testing on my Mark II, and it easily betters Wilson's specs. On-the-air tests have been very favorable, and transmit audio quality is reported as excellent. There is plenty of receive audio, very clean with no apparent distortion. All of the controls on the top of the HT are easy to operate, and there is a HI-LO power switch on the bottom of the case. I normally leave my Mark II in the low-power position (1 Watt), since the difference in power is only noticeable in fringe areas. Low power reduces the drain on the battery by a fair amount and allows extended operating. Incidentally, the battery is a sealed, single-piece unit small enough to allow a second one to be carried in your pocket.

Receiver Description

The receiver is a double-conversion superhet with a MOSFET rf and a J-FET mixer. The first i-f is at 10.7 MHz. A 2-pole crystal filter is used for good intermod and secondary image performance. The signal is downconverted to 455 kHz, passed through a sharp ceramic filter, and then limited and detected. The discriminator uses a ceramic-type transformer and requires no alignment. The receive crystals are in the 14-MHz range and are multiplied directly to F_O − 10.7 MHz by the tuned circuits in the oscillator. Each crystal has individual trimmers for precise adjustment. The total squelched drain of the receiver is 15 mA, which allows many hours of monitoring.

The transmitter oscillator uses crystals in the 12-MHz range. Again, individual trimmers are provided to permit exact frequency adjustment. A phase modulator is used, with mike audio provided by a 2-stage amplifier. A speech clipper is used to prevent overmodulation; full modulation is obtained even when speaking a few inches away from the Mark II. Conventional transistor multipliers get the signal up to 2 meters, and a Motorola MRF 237 is used in the final stage. Incidentally, the 4-Watt Mark IV uses the same final as the Mark II. According to the schematic, the only difference in the two units is the driver transistor. The Mark II uses a 2SC741 and the Mark IV uses an MRF515. Presumably, one could replace the driver transistor, retune, and have a 4-Watt unit for less than the price differential between the Mark II and Mark IV. Maybe there is more to it than that, although I have found that 2.5 Watts is more than enough power anyway.

A solid-state T/R switch is used, and there is absolutely no noise when going from transmit to receive or back. My old HT-200 has an annoying squelch tail under the same conditions, so this characteristic of the Mark II is very welcome.

Construction

The overall construction of the Mark II is very compact, but servicing should be no problem since all the components are easily accessible. The unit is built on one single-sided PCB and uses very conventional parts—there are no custom micro circuits or even ICs. In view of this, I can't help but wonder why it took so long for anyone to develop a miniature HT. I have noticed that the

receiver and transmitter are adjacent to each other; perhaps in the past others have used more restrictive layouts to keep the two functions separated.

Accessories

In spite of its small size, there is room for installation of a touchtone pad or tone squelch option. Conventional desk- and wall-type chargers are available, along with a very attractive speaker-mike for remote operation. A leather case and 12-V car-lighter charger complete the list of accessories.

Operating and Service Manual

An excellent 22-page manual is provided with the Mark II. A detailed technical description is in the manual. Service aids include a foldout schematic, illustrated parts layout, parts list, PCB foil parts overlay, and voltage measurement chart. The manual also contains a section on isolating problems down to individual stages. If service is ever required, all the information one could want is in the operating and service manual. A 90-day parts and labor warranty comes with the Mark II.

What Do You Do With An HT, Anyway?

Like many people who have been on 2 meter FM for a while, I am way past the excitement of 100-mile HT-to-repeater contacts and have discovered that intelligent use of the HT can really enhance many situations. My wife happens to have an amateur license, and we use HTs to keep in touch when we go shopping. The Mark II is small and light enough to fit in her purse, and we can go our separate ways in shopping malls and still easily rendezvous by a quick call on the HT. It's also great for garage sales. I wait in the car listening to FM stereo, and if she spots anything interesting inside (like a KWM-2 for $50.00), I can run in and survey the merchandise. As a matter of fact, she has gotten so attached to the Mark II that I never get to use it and am back to using my old HT-200. *Wilson Electronics Corporation, PO Box 19000, Las Vegas NV 89119; (702)-739-1931.* Reader Service number W2.

Ham Help

I would like very much to use my Radio Shack TRS-80 Level II 16K microcomputer along with an interface to send and receive CW on my Yaesu FT-101E transceiver. However, to this date I have been unsuccessful in removing the bright flashes which appear on the video display when transmitting on any ham band.

One might be inclined to think that the transceiver is entirely to blame for the RFI on the video display, but I must add that the FT-101E does not cause any TVI with my home TV when it is operated in the same place as my video display or any other location in the ham shack.

The video display furnished with the TRS-80 has a "hot chassis," i.e., the chassis or internal system ground is returned to the 120-volt neutral through the power cord. Such a video display might be called an ac/dc power supply by some; the home TV has a conventional power supply. Perhaps the conventional power supply is less likely to have interference from a transmitter.

To this date, I have tried isolation transformers, power line filters, many combinations of bypass capacitors, grounding to the same ground on the FT-101E, ferrite toroid filters, and every combination of any or all of these, and none has removed the flashes on the video display.

I would like very much to hear from anyone who has solved the flashing in the video display.

The long-dormant Royal Order of Hootowls has been rechartered, and its members are again burning the midnight oil on 6 meters throughout the Southwest. I am the new custodian, and I'm attempting to contact all amateurs who were members of the original order. Original Owls may reactivate by submitting to me their name, call, mailing address, and ROHO number, along with a one-time fee of $1.00. Those who do not wish to reactivate are invited to send the information so that they may be included in the ROHO directory. A fact sheet on membership requirements is available for an SASE.

Pittsfield ME 04967

Can anyone assist me in obtaining a tube for an antique Westinghouse regenerative receiver, an Aeriola Sr., type RF, style 319564, made circa 1910-1920? The tube is a WD-11, Aeriotron, style 319533. The tube base is 4-prong, and has a 1½-volt filament and 22½-volt B+. The receiver is a wooden box, with a wooden chassis, rheostat, tickler, and tuning coil arrangement designed to tune 300-500 meters. I will gladly pay a reasonable price and postage for an original replacement, and welcome any advice on what to do with this nostalgic old doorstop.

Social Events

MUSKEGON MI
MAR 30-31

The Muskegon Area Amateur Radio Council is sponsoring the ARRL Great Lakes Division Convention and Hamfest at the Muskegon Community College in Muskegon, Michigan, on March 30-31, 1979. This event will feature manufacturers' exhibits, technical forums, and a large swap shop. Ample parking and dining facilities are available. Friday evening at the Muskegon Ramada Inn, there will be a "Ham Hospitality" with libation courtesy of the MAARC and a Wouf Hong initiation. For additional information, contact MAARC, PO Box 691, Muskegon MI 49443, or H. Riekels WA8GVK, (616)-722-1378/9.

WORCESTER MA
MAR 31

The WPI Wireless Association will sponsor its first annual Spring Flea Market on Saturday, March 31, 1979, from 9:00 am to 4:00 pm, at the WPI campus in Worcester, Massachusetts. For more information, write WPI Wireless Association, Box 2393, Worcester Polytechnic Institute, Worcester MA 01609.

ST. LOUIS MO
MAR 31

Mayor Conway of St. Louis has proclaimed March 31st as Amateur Radio Day, and, in conjunction with this, the Gateway Amateur Radio Association is sponsoring a hamfest which promises to be a good one. Hamfest hours are 8:00 am to 6:00 pm at the H. J. Cervantes Convention Center. Scheduled events include: Wayne Green on microcomputers, an antenna forum by Hy-Gain, an FM and repeater forum by Motorola and VHF Engineering, FCC Q & A, a station-design forum by Drake, a low-cost transceiving forum by Atlas, a linear amplifier forum by ETO, a DX forum featuring the Navassa group and N9MM, a revolutionary method of learning Morse code, and an OSCAR forum. There will be special meetings for teenage hams, Ten-Ten members, Breakfast Clubbers, SWOT members, YLRL members, and others. Activities for YLs include a fashion show, a cosmetic display, and a tour of St. Louis. Talk-in on .34/.94, .37/.97, and .52. Admission is $3.00. For further information, please contact Bob Heil K9EID, PO Box 68, Marissa IL 62257, or phone (618)-295-3000.

COLUMBUS GA
MAR 31-APR 1

The Columbus Amateur Radio Club will hold its first annual hamfest from March 31-April 1, 1979, at the Columbus Municipal Auditorium, US 27 & 280, Columbus, Georgia. Donation is $1.00 at the door. There will be plenty of free parking and overnight free RV space. Exhibitors and flea market will be inside, with a free flea market outside. Talk-in on 28/88. For advance registration and details, write Bob Glasgow N4BGN, 1503 Layard Drive, Columbus GA 31907; (404)-561-7746.

PHILADELPHIA PA
APR 1

The Penn Wireless Association will hold its Tradefest '79 from 8:00 am to 4:00 pm at the National Guard Armory, Southampton Road at Roosevelt Blvd. (Rt. 1), ½ mile south of turnpike exit 28. General admission is $2.00. Setup is at 7:00 am. Sellers may rent a 6' x 8' space for $3.00; you must bring your own table. Some tables are available for $1.00, and a minimum number of power connections are available for $2.00. There will be refreshments, displays, and a rest area. Talk-in on 146.37/.97 and 146.52. For more information, contact Chuck Miller AD3X, (215)-943-3973.

PAINESVILLE OH
APR 1

The 1979 Lake County Hamfest will be held on Sunday, April 1, 1979, from 8:00 am to 4:00 pm at the Lake County Armory, 1289 Mentor Ave., Painesville, Ohio. The hamfest is all indoors. Tickets are available for a $2.00 donation. There will be refreshments, women's activities (ham and non-ham), commercial exhibits, and a 1:00 pm auction. Table rentals will be provided. Prizes include a Wilson Mark II, a Bird wattmeter, and a Drake touch-tone™ mike. Talk-in on .52/.52 and 147.81/.21. There is easy access to the hamfest via I-90 and Rte. 2.

TOWSON MD
APR 1

The Greater Baltimore Hamboree will be held on Sunday, April 1, 1979, beginning at 8:00 am, at Calvert Hall College, Goucher Blvd. and LaSalle Road, Towson, Maryland. The college is located south of Exit 28, Beltway (Interstate 695). There will be food, prizes, and a giant flea market. Admission is $3.00. There will be tables available inside the gym and the cafeteria. For information and table reservations, contact Bro. Gerald Malseed W3WVC at Calvert Hall College, 8102 LaSalle Road, Towson MD 21204, or call (301)-825-4266.

NATCHEZ MS
APR 1

The Old Natchez ARC Hamfest will be held on Sunday, April 1, 1979, at the Natchez Convention Center, Natchez, Mississippi. The event will be indoors and air-conditioned. There will be free admission and swap tables. Talk-in on 146.31/.91 and 146.52. For information, write ONARC, 1226 Magnolia Avenue, Natchez MS 39120.

WELLESLEY MA
APR 7

The Wellesley Amateur Radio Society will hold its annual auction on Saturday, April 7, 1979, beginning at 11:00 am at the Wellesley High School

Reader Service—see page 195

cafeteria on Rich Street, Wellesley, Massachusetts. The doors will open at 10:00 am. Talk-in on .96/.36, .63/.03, .04/.64, and .52. For more information, contact Kevin P. Kelly WA1YHV, 7 Lawnwood Place, Charlestown MA 02129.

COLUMBIA MO
APR 7

The Columbia Hamfest will be held on Saturday, April 7, 1979, from 7:00 am to 4:00 pm at the Cosmo Recreation Center, Columbia, Missouri. There will be a large flea market, forums, and a buffet supper on Friday, April 6, 1979, at the Heritage House. Tickets are 4 for $5.00 in advance and $2.00 each at the door. Food and camping and hotel/motel accommodations will be available. There will be bingo and a special program for the ladies. FCC exams will be administered for Extra, Advanced, General, and Technician Class licenses. Mail completed form 610 to License Examinations, Central Missouri Radio Association, PO Box 283, Columbia MO 65201. There will be a variety of major and minor prizes including a Kenwood TS-520S and a Wilson Mark II. Talk-in on 3963 kHz, 146.16/146.76 and 223.34/224.94. For ticket information, send check or money order, plus an SASE, to John Malinak WD0AFA, PO Box 283, Columbia MO 65201.

ROCHESTER MN
APR 7

The Rochester Amateur Radio Club and the Rochester Repeater Society will hold their Rochester Area Hamfest on Saturday, April 7, 1979, at St. John's School Gymnasium, 490 W. Center St., Rochester, Minnesota. Doors will open at 8:30 am. There will be a large indoor flea market for radio and electronic items, prize raffles, refreshments, and plenty of free parking. Talk-in on 146.22/.82. For further information, contact RARC, c/o K0TS, 2514 N.W. 4th Ave., Rochester MN 55901.

ST. CLAIR SHORES MI
APR 8

The South Eastern Michigan Amateur Radio Association will hold its twenty-first annual hamfest on April 8, 1979, from 8:00 am to 3:00 pm at South Lake High School, 21900 E. Nine Mile Road at Mack Ave., St. Clair Shores, Michigan. For additional information, contact Mark C. Wilke WD8RDA, Secretary, 171 Merriweather Road, Grosse Pointe Farms MI 48236.

MADISON WI
APR 8

The Madison Area Repeater Association, Inc., will hold its seventh annual Madison Swapfest on Sunday, April 8, 1979, at the Dane County Exposition Center Forum Building in Madison, Wisconsin. Doors will open at 7:00 am for sellers and exhibitors and at 8:00 am for the public. The Forum Building has over 20,000 feet of space for exhibitors and the flea market. There will be plenty of space for parking, with overnight camping available. Hotel accommodations are also available within walking distance of the Swapfest. There will be door prizes, an all-you-can-eat pancake breakfast, and a Bar-B-Q lunch, as well as free movies throughout the day. Admission is $1.50 in advance and $2.00 at the door. Tables are $3.00 in advance and $3.50 at the door. Children twelve and under are admitted free. Talk-in on WR9ABT, 146.16/.76. For reservations or information, write M.A.R.A., PO Box 3404, Madison WI 53704.

WEYMOUTH MA
APR 21

The South Shore Repeater Association will hold its ham auction on Saturday, April 21, 1979, at Central Junior High School on Broad Street, Weymouth, Massachusetts. The doors will open and check-in starts at 9:00 am for those wishing to participate. Doors will open to the general public at 12:00 noon. The club will share 10% of the sales. Please tag all items with call and description. There will be refreshments and door prizes available. Talk-in on 147.90/.30 and .52. For more details, write South Shore Repeater Association, Town Hall Annex, 402 Essex St., Weymouth MA 02188.

KANSAS CITY MO
APR 21-22

The P.H.D. Amateur Radio Association, Inc., of Liberty, Missouri, will sponsor the tenth annual Northwest Missouri Hamfest on Saturday and Sunday, April 21-22, 1979, from 11:00 am to 5:30 pm on Saturday, and from 10:00 am to 5:00 pm on Sunday, at the Kansas City Trade Mart. The Trade Mart is located at the Kansas City Downtown Airport, with easy access to all area interstate highways, with unlimited parking adjacent to the 45,000 sq. feet of exhibition space. Display booth spaces are available at a minimal cost of $15 for a single and $25 for a double. For further information, contact L. Charles Miller WA0KUH, 7000 Northeast 120th Street, Kansas City MO 64166, (816)-781-7313.

RALEIGH NC
APR 22

The Raleigh Amateur Radio Society will hold its seventh annual hamfest on April 22, 1979, at Crabtree Valley Mall, US 70 West, Raleigh, North Carolina. General Admission is $3.00 with activities beginning at 9:00 am. There will be a covered flea market and many prizes which include a Kenwood TS-520S or Icom 211 (your choice), a kilowatt three-element tri-band beam, and a CDE rotator. FCC Amateur exams will be administered at 9:00 am sharp. Talk-in on 146.04/146.64 WR4ACF and 146.28/146.88 WR4AOE. For additional information, details, or reservations, write RARS Hamfest, PO Box 17124, Raleigh NC 27609.

NEWINGTON CT
APR 22

The Pioneer Valley Repeater Association will hold its flea market and auction on Sunday, April 22, 1979, from 10:00 am to 5:00 pm at Newington High School, Newington, Connecticut. Tables, chairs, and electricity will be provided. There will be a flea market, an auction, dealer displays and sales, planned family activities, door prizes, free parking, and food service available. For further details, contact Arnie Depascale K1NFE, PO Drawer M, Plainville CT 06062, or Evangelo Demetriou, 38 Volpe Court, New Britain CT 06053.

DIXON IL
APR 22

The Rock River Radio Club will hold its 13th annual hamfest on Sunday, April 22, 1979, at the Lee County 4-H Center, 1 mile east of the junction of Rts. 52 & 30, south of Dixon, Illinois. MAY 5

The 3-F Amateur Radio Club will hold its annual swapfest on Saturday, May 5, 1979, from 8:00 am to 3:00 pm, at the Neenah Labor Temple, 157 S. Green Bay Road, Neenah, Wisconsin, just off Highway 41 at the Highway 114 or 150 exit. Facilities include a large parking area and a large indoor swap area with a free auction at the end of the day. Food and beverage will be available. Advance admission for tickets and tables is $1.50; $2.00 at the door. Talk-in on 52/52. For reservations, write to Mark Michel W9OP, 339 Naymut Street, Menasha WI 54952.

LOGANSPORT IN
MAY 6

The Cass County Amateur Radio Club will hold its second annual hamfest on Sunday, May 6, 1979, from 7:00 am to 4:00 pm at the 4-H fairgrounds, Logansport, Indiana. Go north of Logansport on Highway 25, turn right at Road 100, and follow the QSY signs. Admission is $1.50 in advance and $2.00 at the gate. Outside set up is free and undercover set up is $1.00. Bring your own tables. There will be overnight camping, refreshments, ladies' bingo, and door prizes. Talk-in on 146.52 and Logansport repeater 147.78/.18. For information, write Dave Rothermel K9DVL, RFD 4, Box 146G, Logansport IN 46947.

DEKALB IL
MAY 6

The Kishwaukee Radio Club and the DeKalb County Amateur Repeater Club will hold their 21st annual indoor/outdoor hamfest on Sunday, May 6, 1979, from 8:00 am to 3:00 pm at the Notre Dame School, 3 miles south of DeKalb between highway 23 and South 1st St. on Gurler Rd., DeKalb, Illinois. Tickets are $1.50 in advance; $2.00 at the door. Indoor tables are available or you may bring your own. The outdoor setup is free. Talk-in on 146.13/.73 and 94. For tickets and directions, send an SASE to Howard Newquist WA9TXW, PO Box 349, Sycamore IL 60178.

WARMINSTER PA
MAY 6

The Warminster Amateur Radio Club will hold its fifth annual "Ham-Mart" flea market and auction on Sunday, May 6, 1979, from 9:00 am until 4:00 pm, at the William Tennent Intermediate High School, Street Road (Route 132), two miles east of York Road (Route 263), Warminster, Bucks County, Pennsylvania. A registration fee of $1.00 per car includes one ticket for door prizes. Tailgating is $2.00 additional. Indoor tables are available for $3.00 each. Talk-in on 146.16/76 and 146.52. For further information, please write Horace Carter K3KT, 38 Hickory Lane, Doylestown PA 18901, or phone (215)-345-6816.

FRESNO CA
MAY 11-13

The 37th annual Fresno Hamfest will be held on May 11-13, 1979, at the Sheraton Inn, Clinton and Highway 99, Fresno, California. The program includes technical talks, swap tables and flea market, transmitter hunt on 2 meters (146.52), QLF contest, ARRL CD appointees meeting, ARRL-FCC forum, commercial exhibits, prizes, eyeball QSOs, prime rib banquet, and more. For full registration and eligibility for pre-registration prize, send in $17 before April 27, 1979; it's $19 and no pre-registration prize after that date. Talk-in on 146.34 /146.94. For more information, contact the Fresno Amateur Radio Club, Inc., PO Box 783, Dept. HF, Fresno CA 93712.

DEERFIELD NH
MAY 12

The Hosstraders Net will hold its 6th annual tailgate swapfest on Saturday, May 12, 1979, at the Deerfield Fairgrounds, Deerfield, New Hampshire. There will be covered buildings, in case of rain. Admission is $1.00, with no commission or percentage. Commercial dealers are welcome at the same rate. Excess revenues will benefit the Boston Burns Unit of the Shriners' Hospital for Crippled Children. Last year we donated over $1100.00. Talk-in on .52 and 146.40-147.00. For more information, send an SASE to Joe DeMaso K1RQG, Star Route, Box 56, Bucksport ME 04416, or Norm Blake WA1IVB, PO Box 32, Cornish ME 04020, or check the Hosstraders Net on Sundays at 4:00 pm on 3940 kHz.

VANCOUVER WA
MAY 12-13

The Fort Vancouver Hamfair will be held on Saturday and Sunday, May 12-13, 1979, at Clark County Fairgrounds, Vancouver, Washington. Registration is $4.00 per person which includes a drawing ticket. Tickets are also available at the door. Activities will include contests, seminars, commercial and amateur displays, family events and a large ham radio flea market. Many prizes will be awarded with the grand prize being an Icom IC-701 HF transceiver and power supply. The fairground facilities include trailer parking and ample car parking. A catered buffet dinner is scheduled for Saturday night with musical entertainment included. Price of the dinner ticket is $5.00 for adults. For registration, contact Ken Westby W7DYX, Registration Chairman, 606 Miami Court, Vancouver WA 98664.

DAYTONA BEACH FL
MAY 12-13

The Daytona Beach Amateur Radio Association, Inc., will hold its first hamfest on May 12-13, 1979, at the Holiday Inn Surfside, Daytona Beach, Florida. For Mom and the kids, there is the "drive-on" ocean beach, and shopping in the oceanside plaza. Advance registration is $3.00 per family and $3.50 at the door. For more details, contact Funfest chairman David Rusler WA4ZTT, 1725 Hope Drive, Ormond Beach FL 32074.

SALINE MI
MAY 13

The ARROW Repeater Association will hold its annual Swap and Shop on Sunday, May 13, 1979, at the Saline, Michigan, fairgrounds. Admission, including parking on the fairgrounds, is $1.50 in advance and $2.00 at the door. There will be food, prizes, and a covered area for trunk sales, as well as indoor tables. Because of Mother's Day, wives will be given free admission. Talk-in on 146.37/97, 223.18/224.78, and 448.5/443.5 MHz. For additional details, write ARROW, PO Box 1572, Ann Arbor MI 48106, or call George Raub AD8X at (313)-485-3562.

BENSENVILLE IL
MAY 19

The Radio Amateur Megacycle Society will hold its third Antenna Measuring Contest on Saturday, May 19, 1979, starting at 10:00 am on the grounds of the Flick-Reedy Corporation, corner of Thorndale and York Roads, Bensenville, Illinois. Equipment will be available to measure the gain and swr of 2 meter, 1¼ meter, and 70 cm antennas. Equipment for higher frequencies will be brought if advance request is made. Prizes will be awarded for the highest-gain antenna in each category. Refreshments will also be sold. For further details, including directions, write Joe LeKostaj WB9GOJ, 2558 N. McVicker Ave., Chicago IL 60639. Please enclose an SASE.

CADILLAC MI
MAY 19

The Wexaukee ARA will hold its 19th annual swap and shop on Saturday, May 19, 1979, from 9:00 am until 4:00 pm at the National Guard Armory, 415 Haynes Street, Cadillac, Michigan. Tickets are $2.00. There will be free parking and lunches available. Talk-in on 146.37/.97. For more information, contact Robert Bednarick WD8RZL, Publicity Director, Wexaukee ARA, Cadillac MI 49601.

DURHAM NC
MAY 19-20

The Durham F.M. Association will hold its annual Durhamfest on Saturday and Sunday, May 19-20, 1979, at the South Square Mall, Durham, North Carolina. Plenty of prizes, exhibits, and programs will be offered, and the XYLs can enjoy shopping. Ladies' bingo will be held on Sunday. Free tailgating spaces, under a covered, drive-in-and-sell flea market, come with a one-time $3.00 general registration ticket, with vendors and dealers included. Electrical power will be available. Harmonics and unlicensed XYLs are admitted free. Talk-in on 147.825-.225, 146.34-.94, 222.34-3.94. For more information, write DFMA, Box 8651, Durham NC 27707.

BIRMINGHAM AL
MAY 19-20

The Birmingham Amateur Radio Club will hold Birminghamfest '79 and the Alabama State Convention on May 19-20, 1979, at the Birmingham-Jefferson Civic Center Exhibition Hall, Birmingham, Alabama. There will be many of last year's exhibitors, including most major manufacturers and distributors. There will also be a huge indoor flea market, lots of exhibit space, meetings, forums, activities, and plenty of free parking. Plans are being made to again offer on-site FCC exams on Saturday morning. Prizes will feature at least three complete HF stations, several VHF rigs, and a home video tape recorder system. The Saturday night banquet will feature the nationally known comedian and Grand Ole Opry member Jerry Clower. Banquet tickets will be available in advance, by mail, while they last. For more information, write Birminghamfest '79, PO Box 603, Birmingham AL 35201.

WEBSTER MA
MAY 20

The Eastern Connecticut Amateur Radio Club will sponsor an electronics flea market from 9:00 am until 6:00 pm, with an auction at 1:00 pm, on May 20, 1979, at Point Breeze Restaurant, Webster, Massachusetts. It will be held rain or shine. For more information

A Speedy Spinner Mod

—5,000,000 Hz per minute

Knobify your rig with a minimum of effort.

After purchasing a Kenwood 820 and a Kenwood TS-700A last year, I discovered that something was missing on these two superb rigs. They needed spinner knobs so that I could QSY rapidly across the bands. So I developed a knob that can be affixed to just about any type of receiver or transceiver with a minimum of effort.

To build your own knob, refer to the labeled parts shown in Photo A.

Step 1. Place no. 2 over no. 1 and no. 3 over no. 2. Use a rivet tool or a punch on the no. 1 stem to flange it. After the stem has mushroomed, place a drop of 30-weight oil or white lube around it to ease rotation. After that, use emery paper on the base of no. 1 so that the epoxy has a good surface to adhere to.

Step 2. Epoxy no. 4 to no. 5 and let it set 10 minutes. Press no. 5 into no. 6, and then epoxy no. 7 into no. 6 and no. 8 on top of no. 6. This completes the knob.

Step 3. Take the completed top portion and lubricate the stem, no. 4 (white lube), and press it into the bottom section. The knob is now ready for mounting.

Step 4. Before mounting, make sure that both the knob surface and the rig surface are clean of oil and grease. Apply epoxy on the outer edge of the big knob and let it set for at least one hour. Then QSY rapidly across the ramps. ■

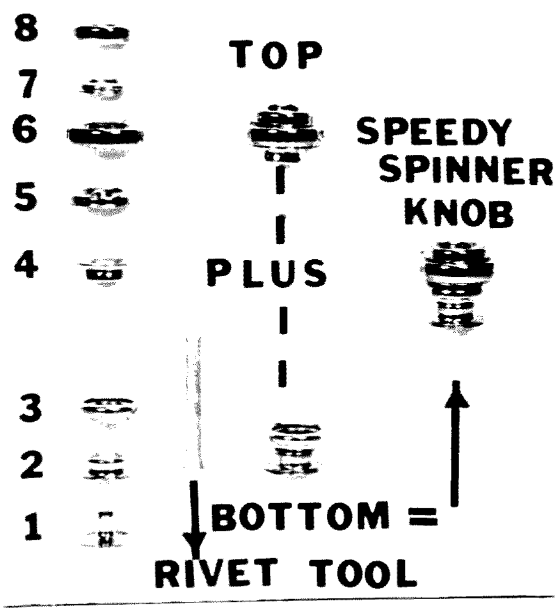

Photo A. Parts and their order for knob assembly.

Photo B. Spinner knob on the TS-700A.

Parts List

5-minute epoxy	$1.59
E Z heavy-duty snap fastener, no. 751	2.00
Prims halo buttons, 212-24 9/16"	.70
Prims halo buttons, 212-30 3/4"	.70

A Variable Bandpass Active Filter

—extremely simple design

Clean up those sine waves!

Allan S. Joffe W3KBM
1005 Twining Road
Dresher PA 19025

The op amp configured to produce an "active filter" is of general interest to the present-day ham for several reasons. His activities span a greater range of technology, op amps are rather inexpensive, and the final filter is a small unit that usually does a big job in a simple manner.

The bandpass type is rather useful for voice, CW, or RTTY modes, but the usual versions suffer from the lack of a diddle pot to vary the bandwidth without substantially affecting the design center frequency.

Fig. 1 shows a familiar bandpass filter without the variable bandwidth element. Fig. 2 shows the same circuitry with adjustable bandwidth and values for a center frequency of about 800 Hz. Using 5% value components, the measured peak frequency lucked out to be 820 Hz with the variable pot turned fully clockwise. This position is the broad position of the filter. With the pot turned fully counterclockwise (the sharp position of the filter), there is a slight shift of the center frequency to 865 Hz, but to the ear this is not detectable.

In the broad position of the filter, the bandwidth at the 3 dB downpoints is a measured 718 Hz. The bandwidth at the 10 dB downpoints is 1890 Hz. In the sharp position, the bandwidth at the 3 dB downpoints is 275 Hz and 800 Hz at the 10 dB downpoints of the response curve. Naturally, as the pot is rotated, you can generate a series of bandwidths between these maximum and minimum limits.

With a plus and minus nine-volt supply for the 741 op amp, the available output swing is about five volts rms. There is a difference in the input sensitivity between the sharp and broad positions of the bandwidth control pot. In the sharp position, it takes about 1.2 volts in to produce the five volts out. In the broad position, this input voltage rises to about 2.7 volts.

The filter demands an input resistance of no more than 22k Ohms from the input terminal to ground, especially when the bandwidth control is set to the sharp position. If this condition is not met, the filter will oscillate, a fact that may come in handy. To illustrate, set the bandwidth pot to the maximum sharp position without any input termination. A scope on the output will show a sine wave with clipped peaks. If you slowly back off the bandwidth control, the clipped peaks will go away, leaving you with a rather nice clean sine wave that also has excellent frequency stability. The frequency of this oscillation will be close to 77% of the center frequency of the filter. ■

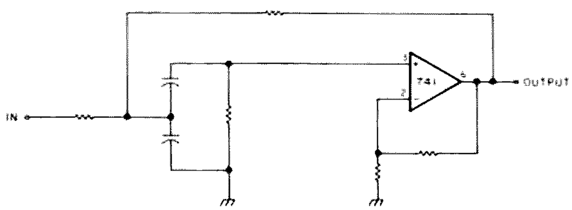

Fig. 1. Fixed bandwidth.

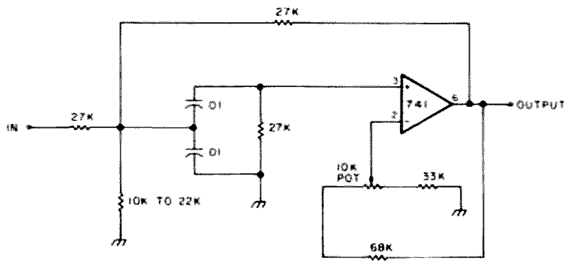

Fig. 2. Variable bandwidth.

What About an Active Antenna?

—here's a look at one

Mixed results.

Carl C. Drumeller W5JJ
5824 NW 58 St.
Warr Acres OK 73122

What's an active antenna? Usually, it is an antenna—often much smaller than normal size—that contains an amplifier in its structure. The amplifier is intended to bring signal strength up to a level comparable to that provided by a full-size antenna.

Recently, an importer commissioned this writer to investigate the capabilities of an active antenna. It's a model YN-1000B SKYNIX Electronic Antenna. The accompanying information makes no mention of the manufacturer, or even of the nation in which it was made. This arouses a strong suspicion that it is a "bootleg" copy of a similar antenna developed in Germany about 15 years ago.

The supplied information claimed a frequency range from 150 kHz (the European long-wave band) through 108 MHz (the FM broadcast band). This range makes use of two internal amplifiers, one with 15 dB gain for all the entertainment broadcast bands, and one of 10 dB gain for the shortwave bands. The internal amplifiers operate on 12 V dc, draw 8 mA, and require a negative ground.

Frequency in kilohertz	Meter Deflection Inside Antenna	Active Antenna	Outside Antenna
640	S9 + 10 dB	S9 + 20 dB	S8
940	S9 + 5	S9 + 5	S9
1560	S9	S6	S9 + 15
6150	S9	S0	S9
9000	S9 + 15	S9	S9 + 20
10,500	S9 + 15	S9	S9 + 20
11,800	S7	S0	S9 + 10
15,100	S9 + 15	S9	S9 + 10
21,500	S9 + 15	S9 + 15	S9 + 20
27,000	S9 + 20	S9 + 10	S9 + 25

Fig. 1. Tabulated results.

Armed with this information, I set up a test bench. The active antenna was mounted on a ground plane simulating a car body. Leads were run to two other antennas for comparison. One antenna was a 15-foot length of wire strung up in the same room with the active antenna, thereby putting the two under equal site limitations. The third antenna was a multiband (trap) dipole at a height of fifty feet. Provision was made for rapid shifts among the three antennas.

A general-coverage receiver, the Yaesu FRG-7, was selected for the test, and since the trap antenna would have quite good response on the amateur bands, to make a fair comparison, it was necessary to avoid checks too near amateur frequencies.

The results obtained are shown in the accompanying tabulation. (See Fig. 1.) No attempt will be made to explain the very wide variations, as no consistent pattern was established.

It is evident, though, that the active antenna finds its best application in receiving signals in the 540-to 1650-kilohertz frequency range. It's quite impressive to see an antenna only 15¼ inches long bring in signals as well as (or even better than) an antenna twelve times as large! It's possible that it might display equal ability in the VHF-FM bc band, but I had no receiver in that range with sufficient internal shielding, or a dependable S-meter; therefore, no test was made in that range.

To sum up, this one version of an active receiving antenna should be quite acceptable for reception in the MF AM bc spectrum, tolerable in some portions of the HF spectrum, and quite unsatisfactory in other HF ranges. There are other active antennas marketed in this country and in England that may be fully satisfactory. ■

LETTERS

from page 10

ly dropped A-1. Just within the past year I decided to go for DXCC and have over 110 confirmed with 40-plus more hopefully en route.

Wish you would change the tenor of your "Never Say Die." Then I probably would drop another ham magazine in favor of *73*.

John H. Pitman W1LY
Quechee VT

CARPING

I have read your magazine for a number of years and do enjoy it. However, I am disturbed at your continual carping at the ARRL, not because the ARRL does not merit considerable criticism, but because at no time have you offered us a suitable alternative.

Most organizations such as the ARRL do become inflexible and self-protective. However, challenging them directly as you do merely increases their tendency to insulation and isolation.

You have the means and, I assume, the staff necessary to develop an organization that might effectively represent the ham radio community. I can visualize an organization, not unlike the National Rifle Association, that could be a potent lobby.

Perhaps rather than indulging in ineffective criticism of the ARRL, you could invest some of your tremendous energy in the development of a real alternative organization, functioning solely in the interests of amateur radio.

Edward M. Schneider, M.D.
AA6O
Woodland Hills CA

Well, Edward, you've raised some points that perhaps should be discussed. I am often asked why I don't start a second national amateur radio organization and some answers are called for.

The question can be approached better by dividing it into parts. First, why I haven't started one in the past. Second, why I don't start one now. Some of the past history has been covered in a recent editorial. Beyond that, without going into the depressing details, I can honestly say that there has been no time when I had either the money or the time needed to get something going.

That brings us up to the present. Why not get an organization started now to do all of the things which the ARRL should be doing but isn't? My feeling is this . . . since the whole future of amateur radio rests upon what frequencies we end up with after WARC this fall, and since little can be done to influence that event at this late hour, perhaps it's best to wait and see what we have left, if anything, to work on.

The organization which I have in mind would be constructed quite differently from the League. It would be based primarily on a local foundation, with very little power in the national organization. We might call it the Institute of Amateur Radio, but perhaps better would be an International Amateur Rabio Lobby (IARL). This would be more in keeping with the goals of the organization. I've belonged to several national organizations which were set up in this way and which function much better than the ARRL as a result.

I see the thrust of the IARL as being on three fronts, all of a lobbying nature. Firstly, there would be a lobby in Washington which would make the FCC aware of the rule changes which amateurs desire. This lobby would push to get these rules accepted, using pressures on the FCC and Congress for this end. I still have the concept of a yearly or semi-yearly conference of the IARL chapters where rule changes would be proposed, discussed, and voted on. This would be almost identical to the system used by the ITU.

Secondly, I see a need for a lobby on a national level. This would be on the order of "Hobby Lobby," for those of you with longer memories. This "lobby" would organize material on amateur radio for newspapers, magazines, television, radio, etc. The main purpose of this effort would be to make amateur radio known and appreciated by the whole country. It would also help interest more people in amateur radio, which wouldn't hurt.

Perhaps even more important in the long run would be international lobbying for amateur radio. This effort would introduce amateur radio into smaller countries and build up a world appreciation for the value of amateur radio. This could reflect to our advantage at future ITU meetings. An international lobby would work with the national ham groups in foreign countries to improve amateur frequency allocations in the future.

Being realistic about the cost of the three lobbying efforts, including the estimated costs of offices, experienced people, travel, telephone, newsletters, etc., we're looking at a minimum cost of $750,000 per year. That comes to about $2 per licensed U.S. ham, which certainly seems reasonable. But by the time you take into consideration the 50% of the hams who are resistant to paying for such a service plus the costs of collecting the needed funds, issuing membership cards, keeping records, sending invoices, statements, etc., you're looking at more like $10 per amateur. It's a formidable administrative job.

Most of us have come to equate the service of a national organization with observable benefits such as contests and certificates. I suspect that the IARL would have to run a full set of contests just to establish visibility. While I personally am a contest fan, you may have noticed that I've kept 73 pretty much out of the contest business, feeling that we have enough contests already. Would the IARL have to run VHF contests, a national contest, an international contest, and perhaps a satellite contest?

Let's see, what else does the ARRL do besides run contests and publish? I think that about covers it. If the ARRL runs contests, lobbies on three levels, and publishes, it should be a viable organization.

There are some serious questions that need answering. For instance, do you prefer a membership which is tied inflexibly to a subscription to the magazine? Keeping separate records is a lot more expensive than doing both together, so a combination IARL membership and subscription to 73 would be cheaper. On the other hand, there might be some amateurs who would prefer not to support an organization devoted to promoting amateur radio and yet would want to read the magazine. Let me know what you think of that.

Another question is one of officers. Would you prefer to have a national election which would select the president of the Lobby, or would you like to go with the ARRL system where the directors select the president and manager? The ARRL system is quite parallel to that in the Soviet Union where the Politburo elects the president and party chairman.

It is tempting to set up a new organization with controls which would make it either difficult or impossible for someone to lose control. This was the system that Hiram Percy Maxim used when he set up the ARRL. The problem with that system was that it resulted in a good deal of infighting and politics within the League as people struggled for control . . . a control that was almost impossible to upset. I'd prefer to avoid this pitfall. What's your thought on this?

For that matter, are there any clubs which feel that the idea of setting up lobbies on three levels is good enough for them to align with? They would thus become a local chapter of the IARL, should such an organization be desirable.

I admit that I should have come up with this plan years ago and should have organized my business and personal life so as to implement it . . . but I didn't. So, if it turns out not to be too late for such an idea, are you with it or against it? And how about that $10? That's consistent with what other national organizations charge, by the way.

Please advise.—Wayne.

NO WINNERS?

After having read your editorial in the December issue, "Never Say Die" seemed to me to be an inappropriate title. Your comments on WARC read as if Wayne Green as well as the ARRL have given up on amateur radio. Statements like "Having been an avid ham for some 40 years, I'll sure hate to lose it. It's been a big part of my life . . ." tend to put "gloom and doom" in capital letters. So if you insist on using "Never Say Die," at least make it mean something—especially now. Make those 40 years of experience count. You're in a position to do so.

Since, like yourself, no one has asked for my opinion, I too feel free to comment. Just as an amateur station is more than a collection of radio gear, so ham radio itself is more than just a hobby. How much more is a matter of record and, in spite of what we as individuals feel concerning the League, it maintains a large file on ham radio as a public service. Hams may not be unknown to the general public, but they're not a household word, either. If ham radio is on the way out, the American public deserves to know what it's losing. That in-

cludes RACES, MARS, and *73 Magazine*. Now is as good a time as any to take an objective look at the whole amateur scene. We can't do it—we're too prejudiced. Someone has to pull ham radio out from under its rock and put it in the spotlight for a few minutes. If the amateur service goes, then commercial and military frequencies may not be sacrosanct either, and Americans may need more than the Citizens Radio Service can offer sometime in the near future.

The WARC '79 conference has been getting about as much national publicity as my last birthday. Ditto amateur radio. The time has come to reach into the dustbin of public service and use it for all it's worth. I propose a network television documentary on the whole shootin' match, written on a level of quality approaching that of *National Geographic*, fully researched, and with films and interviews of those who have been involved on both ends. Let's cover ham radio right from the beginning. If it's on its way down, it might as well go down swinging.

A project of this magnitude takes time, a lot of research, a lot of leg work, a lot of convincing, a lot of good old-fashioned salesmanship, and a lot of bucks. Most of us don't qualify in any of the above areas. Maybe Wayne Green does. Does 40 years of experience agree with my proposal or not?

Nobody has to convince a ham on the value of his hobby—convince the ones who have never heard of it. Amateur radio needs, and perhaps even deserves, national support. But if voter turnout is any indication of American apathy, then we need a lot more than a few local newpaper articles once in a while. All of us seem to require a constant reminder of our past, our present, and our future. My proposal is just a shot in the arm.

If amateur radio is no solution to third-world problems, then neither is its demise. If the African nations get the frequencies they want, can they use them as efficiently as others could? Will it take years for them to implement systems which we already have? I suspect that this latest conference in Geneva may well come out with no winners.

Lee Hughes WA2VPH
Moravia NY

SUCH IS LIFE

Having decided to try my hand at color film and print processing, and seeking a means of working a "good" timer into the budget, I dug out the July '76 issue of *73* with the W1HCI story, "Dependable Timer—for darkroom, repeater, etc." In the same issue is Al Plavcan's schematic for the low priced frequency counter, and this, of course, invited grafting parts of his schematic to that of the timer to give not only a programmable timer but also a straight 0-99 second timer for monitoring the time in the various solutions with digital readout.

I am busily hunting sources, prices, etc., for the few chips needed and expect to wind up with a precise unit at a cost far below that asked for a "normal" darkroom timer.

This prompts me to suggest that you cast about among your many contacts to see if you could stir up a circuit for a home-brew color analyst circuit. The prices asked for such as these are beyond the affordable range of the casual photo nut, and I just bet that a reliable circuit could be put together by a brother ham!

What is needed most sorely is a means of determining the subtractive filtration needed to accommodate the color negative, taking into account the particular characteristics of the print paper. This latter information is printed on each package of paper, at least by Eastman, and surely by all of the others.

I sincerely appreciate the inclusion of "other than radio" items; this is what makes *73* my favorite source.

All of my issues are carefully maintained, readily accessible, and I need not tell *you* how valuable they are as a constant source of reference.

My ham subscriptions are now limited to just two. I finally dropped the old traditional one, for two reasons: 1. Greater mileage obtained from the other two in the amount of usable material. 2. I grew to resent the rather lofty attitude assumed on the few occasions wherein I wrote to ask for clarification of a few technical points.

Apparently I had "sinned" some years earlier when I took occasion to express my thoughts about the seeming lack of proper support for the efforts of Ted Cohen and his "TV/Hi-Fi Task Force." I felt that if there was any specific area wherein the League should show real leadership in the way of aggressive action, this was it. Ted went about the problem extremely realistically and scientifically and laid the foundation for easing one of the most urgent problems of these times, the matter of improperly designed and constructed solid-state entertainment equipment which invited interference from the cleanest of transmitters.

I waited to indulge in color TV until I could find a set which would be both deaf and blind to my Swan 500. A local dealer was kind enough to let me test a few major brands at my home with my transceiver running normal input on 80 through 10 meters on CW, phone, and slow scan. Each TV was 100% solid state. I found that of them all, at that time, three years ago, only the Sony stood up to the test, even though the TV was separated from the transceiver by only 12 feet and was only about five feet from the base of the 4BTV antenna. On the basis of these tests, I bought the Sony color TV, and the Hi-Fi AM/FM stereo 8-track. To this date there has never been the slightest trace of pickup from my ham rig on either of the units in any of their functions.

I sorely wish my neighbors all owned Sony. I get into one of the highest advertised brands even when they have the power plug pulled from the receptacle! Naturally, they cannot be convinced that the fault lies in their own apparatus. Such is life.

Waco TX

SAM HARRIS

No, Sam Harris wasn't born with a beard. He grew it in 1944 when he was employed by Brush Development Co. (sometimes called Brush Bedevilment Co.) on Perkins Avenue in Cleveland, Ohio.

My former wife, Mary, who worked in the same department on the third floor, told me that he trimmed it with tin snips. At the time, I worked on the first floor.

I understand that Sam's real name was East, and that he acquired the name Harris from the family who raised him. From his call letters, he was probably first licensed in 1939.

About the end of WWII, Sam bought a duplex house at 1311-1313 Lakeland Avenue in Lakewood, Ohio. Mary (W8SBB 1938-58, K4UBT 1958-66) and I visited Sam at his home in the 1311 side about Thanksgiving, 1946. Sam was deeply involved with two meters at the time, using mostly military surplus SCR 522 equipment. Also, Helen had bought him a National NC 2-40-C, a low-band receiver he used mostly as an i-f with the SCR 522 receivers as front ends.

Sam's shack was a finished attic room I had used as a playroom as a small boy twenty years before. I had moved from that house when I was 7½ years of age. A playmate of that time, Buss Rhoades, who lived in the 1313 side, also later became a ham, if my information is correct.

In the later forties, I lost contact with Sam except for chance meetings at hamfests. By that time, he had moved to Burton, Ohio, and became well known on seventy-five.

It appears that I lost contact with Sam about the time that Wayne became well acquainted with him.

THE TAY NET

I would like to inform you of a new net made up specifically of operators 19 years old and younger. It's called the TAY Net, which stands for Teen and Younger Net.

The net control is myself, KA0AQZ. The net meets on 28.635 at 2300 UTC every Tuesday. An informal bit of ragchewing usually can be had a half hour before the net on the same frequency.

My age, by the way, is 13 years, and my QTH is Independence MO.

Please, no OM check-ins, unless you have something of interest to our age group. All hams and children of hams are invited to join in the conversation, provided you are 19 or less or have something of interest to that age group.

I would very much appreciate it if you would print this info to increase the activity. *Thank you.*

Brin Moffet KA0AQZ
Independence MO

KISS

The dc-to-dc converter described in "Try a Little KISS," January, 1979, is not as reliable as described. The converter shown in Fig. 1, page 59, would put 12 volts at terminals C-D if any of several components fail:
1. If the zener fails open, it will let R1 saturate Q1 and the output voltage at C-D will be about 12 volts.
2. If R1 shorts, the zener will probably blow before a 10- or 15-Ampere car fuse. Again, 12 volts will appear at C-D.
3. A collector-to-emitter short on Q1 directly applies 12 volts to C-D.

Possible explanations for the reporter test results ("... the output voltage will rise a few tenths of a volt ...") are: a) Terminals A-B were connected to the 12-volt source with very small wire which provided current limiting; or b) the 12-volt source was soft and did not provide a constant 12 volts

Input. Was the input voltage at A-B monitored during the tests?

An electronic "crowbar," i.e., an SCR across C-D, could be added to the circuit to short-circuit C-D in the event the voltage at C-D exceeds the desired output. To prevent damage to the converter, a properly-sized fuse should be inserted in series between A and the transistor, or between the emitter of Q1 and the crowbar. Such a crowbar could be used with a simple zener-resistor regulator.

No circuit is completely component-failproof! Use high-quality conservatively-rated components in any critical application.

Jackson MI

VHF ENGINEERING

I would like everyone to be aware of the fine service one of your advertisers, VHF Engineering, is providing.

I have an old HT 144-B which died. After a prolonged attempt to fix it myself (with expert help), I gave up and sent it to VHF Engineering. They returned it in roughly 2 weeks, several days *before* Christmas. They didn't just fix the unit, however. They gave me a replacement piece of hardware which I had lost, and they also replaced all of the point-to-point wiring (the HT 144-B was a kit), making it look much more professional. All of this was done for the fixed nominal labor fee alone. The parts were supplied free.

I think that this kind of exceptional service should not go unnoticed.

David Rabin WB9PSD
Wilmette IL

NOW HEAR THIS!

As one of many, I have fallen for the attraction of CW machinery. My particular unit is a PET with the excellent attachment Microtronics makes.

While I work many stations on CW, I of course prefer to work other "CW machines" when using this unit, as the copy is then 100% just like the printed page. Hand-sent CW is, as a rule, 85-95% readable if the sender is using an electronic bug and down to 15-25% readable if the sender is hand-pumping with considerable swing. A typical bug error would be "6E" instead of "the" on the screen caused by improper spacing between the "t" and the "h". If it happens once, you can plan on "6Es" all through the QSO because this is that particular operator's habit! In any case, I strongly recommend systems like this; it is really fun and in my case has totally rekindled CW interest.

The reason I am writing is to suggest that a particular frequency be used as a worldwide and preferably bandwide CW-machine calling frequency. If we could settle for some kind of reasonable standard, perhaps we could more easily get together. If speed is kept to a reasonable digit, non-machine-users could hear what we are saying. Thus I suggest the following frequency: XX.069 (for XX, insert 14, 3.5 or whatever). For initial speed, I suggest 20 wpm. This would provide studious code-learners with a readily available standard code speed to practice on, and it's slow enough that it is copied easily enough by ear. .069 is an easy number to remember, for various reasons, and doesn't appear to be any net frequency or the like. Please advise if you know differently.

Now hear this, all you machinists out there: The frequency is XX.069 and the speed is twenty. CU on ur favorite band!

A BELIEVER

I just got home from school and found my copy of *73* had arrived today. As usual, an excellent magazine! I was reading your editorial and have a few comments on the part on page 190, "What about the code?" At first, when I saw your constant advertising for your code tapes throughout your editorial, I thought that was a little uncalled for. But then I began to think. On Monday of this week (Jan. 8), I went and passed my General after upgrading from Technician. Over the summer, I purchased an ARRL code kit with two tapes and all that. I also had one of your 13 wpm tapes. I listened to the ARRL tape, then yours. I thought that I would use the ARRL tape since it was easier to copy. Every once in a while I'd put your tape in the recorder just to try it, but I always gave up. I went to the exam, then it hit me like a hammer: Your tapes are the ones to use. They are sent at the FCC standard and the ARRL tapes are spaced at about 10 wpm. Luckily, I passed, but it would have been a hell of a lot easier if I had stuck with your tapes! It may just be me, but I think the percentage of failures would be about half of what they are now if tapes offered for practice were like yours! I'm a believer! I am a student in high school (10th grade) and have little time to mess with studying for ham exams with school exams to worry about. I think that I could have upgraded with less practice and worry with your tapes.

CONGRATS

I made it through my Extra the second time I took it. I feel I can honestly say that your study guide for this class license was a major factor for my success. Even if one is not interested in getting the Extra, the book makes an excellent reference source. I've always been a poor student, but this book was fun and the learning process painless! I find that now I understand the material as opposed to merely knowing facts and information.

Congratulations on a masterpiece! There were places where I felt you were prolix and/or pedantic, but, on the whole, this book should be hailed as a classic of the study guide genre.

Thank you for helping me achieve my license.

Bob Wanderer WB2MCB
Pompton Lakes NJ

PEANUT BUTTER

Just a note to compliment you on your fine magazines, *73* and *Kilobaud*. I know they must be good because the first postal employee who handies them must tear open the wrappers and all the others down the line must read them during lunch or coffee breaks. So far I have not found peanut butter between the pages, but the way the pages look, I would not be surprised. Too bad you cannot entice these people into their own personal subscriptions! I am sure the problem is not unique to me, and if others save the issues as I do, we appreciate good copies for the bookshelf.

One last note on *Kilobaud*. For years I have been throwing away those super 1st time subscription offers only to finally knuckle under last month to a trial copy. What a super computer magazine! If I could afford it, I would purchase all your back issues of *Kilobaud*.

Keep it up—you've got the only magazines on the market with so much content it takes a month to read.

Roger Syvertsen KØVOD
Brainerd MN

COMM SPEC

I am writing to let you know that one of the advertisers in *73 Magazine*, namely Communications Specialists, is a fantastic firm to do business with.

When I had a problem with an ME-3, I shipped it back to them on a Monday. The following Monday, a repaired unit was waiting for me when I arrived home. Two months later, a different problem arose; again it was shipped back to them with a letter explaining what was wrong. One week later, a brand new ME-3 arrived with a notation that it was replaced under the warrantee. There was *no* hassle or lengthy correspondence.

Organizations such as theirs and *73 Magazine*, who is particular about the advertising that is accepted, deserve all of the praise that can be given to them. Communications Specialists and *73 Magazine* rate very highly on my list. I have been a subscriber of *73* since you published your fourth issue.

Help for the Hearing-Impaired

—don't miss another phone call

See the light?

Note: Telephone company regulations vary regarding attachment of external devices to telephone lines. You should check with your local telephone company offices before using the equipment described in this article.—Ed.

A hearing-impaired member of my family couldn't hear the telephone in some rooms of the house. Sometimes, when I called home, the phone wasn't answered even though I knew that someone was in the house. The major problem turned out to be that the bell was not clearly audible in the room that was used extensively for reading and sometimes for TV. A solution that was acceptable to all was to flash a light when the phone rang. In this case we chose to turn off the circuit that the reading light, hi-fi, and TV were on. It also incidentally turns off the vacuum cleaner in that room, and nobody could hear the phone when that was running. The circuit for the device is shown in Fig. 1.

This device was constructed in one evening out of spare parts as follows: an old power transformer was selected for T, and the high-voltage winding is used for the phone line side. Since the ring frequency is around 25 Hz on most systems, this winding should be rated at a minimum of 200 V ac. The 115-volt winding is then used as the secondary of the transformer. (An audio plate-to-grid transformer could be used the same way if you're old enough to have one of those in the junk box.) An audio generator was then hooked to the high-voltage winding through the capacitor C, and several values were tried to get a maximum 25-Hz voltage across the secondary. In my case, 1.3 uF did the trick, but this value will be different for every transformer.

Relay A is a sensitive dc reed relay that was removed from a computer board. A 12-volt 5k-Ohm relay should work well, but the higher the resistance of the coil, the less load it will put on the ring voltage. Resistor R also serves to raise this impedance, and also helps filter the dc produced by the diode. I would suggest starting with about 2.7k Ohms for R. I used an oscilloscope across a 100-Ohm resistor to measure the current drawn from the line at 25 Hz, and the ratio of voltage to current for my version of the circuit came to 10,000 Ohms. That should be light enough loading not to upset the telephone company. The capacitor keeps you from drawing any dc current.

The contacts on the sensitive relay, A, should not be used to interrupt much current, so it is shown switching a 115 V ac power relay that actually handles the heavy current. I installed the circuit in a box adjacent to the circuit breaker box, and ran two small-gauge wires to the nearest telephone line junction. Now when the phone rings, most of the circuits in the living room go off with each ring and it is not possible for anyone in the room to be unaware of the ringing. The freedom of movement granted to a deaf person expecting a call is well worth the minor inconvenience of occasionally having the lights flash for a few seconds.■

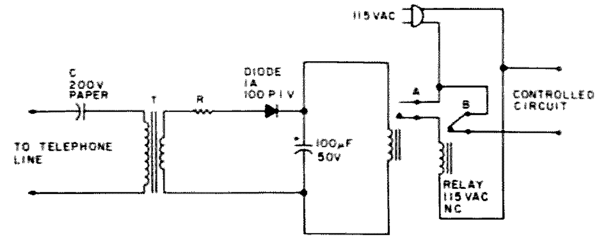

Fig. 1. See text for procedure for finding C, T, R, and A.

Try a Bi-Loop Antenna

—gets you coming and going

Two loops are better than one.

W. W. Davey W7CJB
Rt. 1, Box 121
Charlo MT 59824

This antenna design has performed as well as a 3-element beam on 144 MHz and better than a 2-element full-size yagi on 14 MHz. The idea for this design came from the antenna described by ZF1MA in the December, 1976, issue of *73*. The bi-loop configuration needs to be more or less exact to get the best performance.

Having used single loops in the past and noted their ability to reduce man-made noise, I decided to try for more gain—and still keep the closed loop design. My first experiment was on 144 MHz. It took me a whole ten minutes to nail some 3/4" x 3/4" sticks together and tack a test antenna in place. The antenna was compared with a 3-element yagi on the Lookout Pass repeater, 80 miles distant. The Clegg FM-28 S-meter readings were slightly higher with the bi-loop. Results were repeatable, so it was decided to try the 14-MHz configuration between a couple of poles. In nearly all cases, there was an improvement in signal strength of 1 to 2 S-units over my full-size 2-element yagi. With some signals coming from high angles, there was no difference in signal strength. With low-angle DX signals, though, there was a definite improvement over the yagi. The polarization was vertical.

The normal impedance of a single loop is slightly over 100 Ohms, so when two such loops are fed in parallel, the impedance comes close to a good match for 70- or 52-Ohm cable. This impedance will vary slightly with the height above ground.

As mentioned above, the loops need to be adjusted to an almost-perfect square for best performance. When the extreme ends of the loops were stretched out in a diamond shape to raise the bottom of the loop higher above ground, the low-angle gain fell off in comparison with the yagi.

The lower corner of each loop is only 6 feet off the ground and is kept in place through the use of a one-pound weight which just touches the ground when the loop is taut. Raising the entire array should further improve its performance.

This antenna is simple to build and performs well in two directions. There are deep nulls in the plane of the loops. The maximum radiation is broadside to the wire. Each loop is made up of 73 feet of #14 enameled wire, which makes each side of the loop 18'3". Use lightweight ceramic or plastic insulators and depend on nylon rope for additional insulation. The insulator which terminates the coaxial feedline is shown in detail in Fig. 1.■

Table 1. Swr readings for the bi-loop antenna. Readings on 7 MHz and 21 MHz were high (at least 7:1), but from 28.0 MHz to 29.0 MHz, the swr was almost constant at 1.8:1.

Simple RTTY IDer

—uses five ICs

Automatic operation at the press of a switch.

Paul J. Tew G3MEJ
1-B Morton Road
Morden, Surrey
England SM4 6EF

To provide identification on RTTY without the use of keys or mics, this circuit was used for automatic operation at the press of a switch. It provides a matrix of 80 bits. With a Morse dot = 1 bit, dash = 3, letter space = 3, and word space = 5, it allows for DE and most 5 letter calls, i.e., DE G3MEJ. The DE could be omitted to give sufficient space for longer calls or, alternatively, other ICs could be used to give a matrix of, say, 128, 160, or 256 bits.

A momentary push of the ID button sets the flip-flop and enables the counters, IC1 and IC2. The BCD output of the first counter, IC1, is decoded by the 7442 and the message is selected, via the diodes, by the 74151 and output on IC4, pin 6. Complementary output is available on pin 5. At the end of the count sequence, IC2, pin 11 goes high and resets the f-f ready for the next push.

The clock, IC5A, while perfectly satisfactory, needs careful setting up. A socket for IC5 is recommended. Select a value for R1 (say 1k-4k) while tweaking RV1 to obtain oscillation at pin 6. Then adjust the value of the 100-uF capacitor to give the frequency required. RV1 allows only for a stable start and operation of the clock and is not intended as a frequency adjustment. If the output level at pin 6 is too low, change the IC! Even those of the same make and batch give different results—hence the socket. An alternative clock using a 555 or 7413 might be preferable, but this all makes the PCB larger. Values shown gave a frequency of 10 Hz and a Morse dot length of 100 ms. This is long enough to stop a mechanical printer doing its nut at 45 baud. Note that the reading of CW via two tones may need brain adjustment if you are used to single tone CW. Allow for this before assuming the circuit is not functioning correctly.

Read the matrix as a page, starting at the top left-hand corner and ending at the lower right-hand corner. The diodes can be anything in the junk box, preferably germanium, but silicon also work (1N914, etc.). Note on the matrix that there is a space at both ends of the "message," so that whichever tone is being keyed, there is a break before or after the ID. Otherwise, the first/last ID bit would merely blend into the steady tone state. A PROM could have been used instead of the diode matrix, but they cost real money against peanuts for the diodes.

A convenient PC board size, without getting cramped, is 3 x 4 inches. The output transistor, VT1, should be suitably rated for your own keying arrangements.■

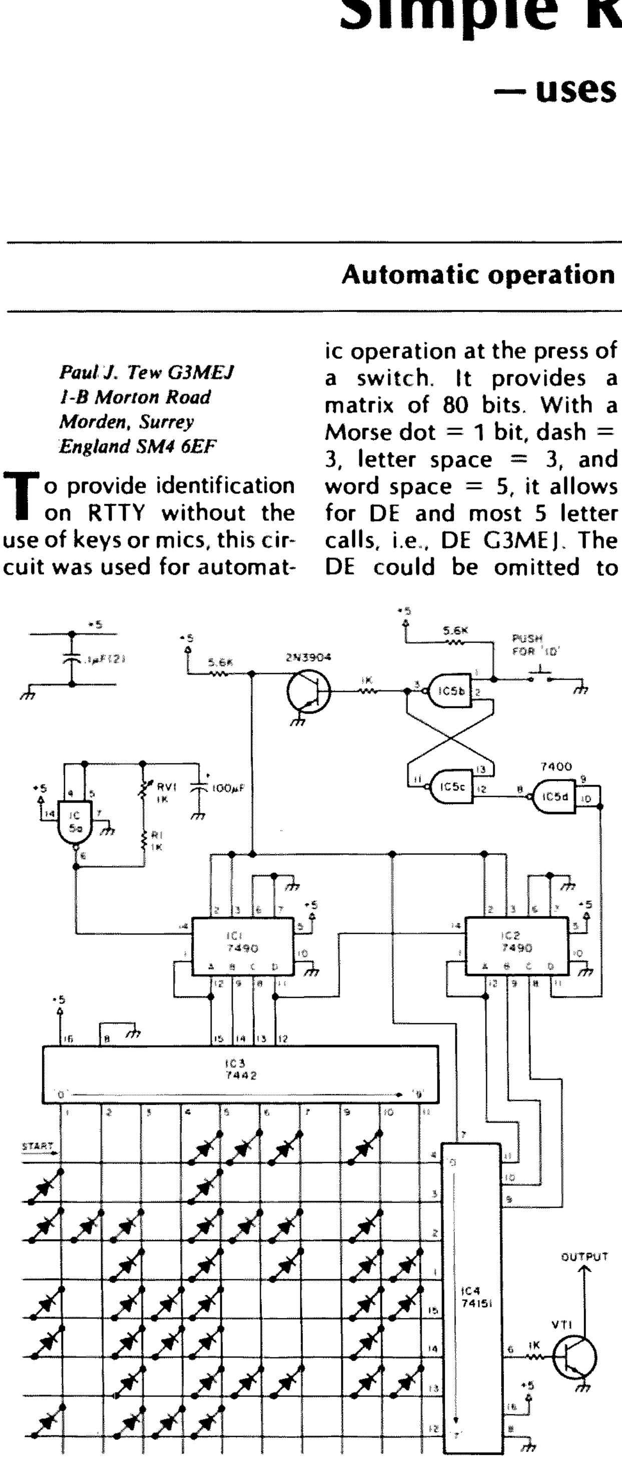

Fig. 1. CW IDer.

Tales of Speech Processing

—including a practical design

Tolerating the screamers and whisperers.

Thomas C. Harper WA4JHS
11109 Carmon Street
Riverview FL 33569

Conversation overheard on 20 meter band, SSB:

"Old man, I'd like you to give me a report—I want to switch in my processor and see what it sounds like. . ."

"OK, switch it on. You're about 5 and 9 now."

"★'#"&'#★'&2&?"

". . . Ah. . . Yeah. . . Ah. . . Sounds pretty good. . . Really brought my S-meter up. But I think I missed the question . . . Try me again."

Anyone who works even a little SSB regularly has heard that conversation, usually many times. At the same time, we are all familiar with the low duty cycle characteristics of human speech. This attribute of speech has led to many schemes, some wilder than others, but all aiming to improve information transfer by speech. And listening on the bands tells one that some of the more elaborate designs can sound as awful as some of the more rinky-dink ones.

A short history of speech processing is probably in order. The basic character of speech has been known since at least the advent of the oscilloscope; and in the old AM days, several transmitters (Heath/Johnson/others) incorporated speech clipping followed by a suitable filter. The reason for the filter was obvious: when the top is lopped off a signal, harmonics are generated, increasing the modulation bandwidth and causing a fuzzy sound in the recovered audio. Some of these clipper/filters were very simple and straightforward and some of them sounded very good, with a tremendous improvement in intelligibility; some of them sounded awful.

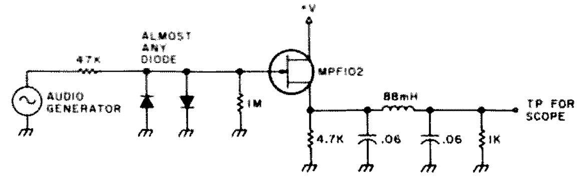

Fig. 1. Demonstration clipper/filter.

Then SSB came along, and at first it sounded awful enough to the AMers without complicating the whole thing with speech clipping/processing. In fact, in the great SSB vs. DSB controversy of the 1950s, reported in the proceedings of the IRE and other journals, it was alleged that one of the problems of the then "new" SSB was that it didn't lend itself to simple speech processing. This attitude persisted for many years, even though some unreconstructed mavericks were using speech clippers of one kind or another on SSB, and they could see a difference on the plate current meter. Some of them neglected to mention to their contacts that they were using clippers. Possibly there were some guilt feelings, especially after hearing conversations such as the one above.

A hairy mathematical proof made the rounds and found its way into the *Handbook* (ARRL). It demonstrated to everyone who had been through first year trig that clipping at audio for SSB was wrongheaded and possibly dangerous. It had terms like $Sin^{n}X$, where n was between zero and one. Oh, it was wonderful! Mathematicians rejoiced at the elegance of it.

There appeared to be one unwarranted assumption, however, and that was that the operator would attempt to modulate an SSB transmitter with these (nearly) square-topped waveforms. And as the argument proved, you can't reproduce square waves directly using

SSB. Neglected was the fact that most operators would have used a filter after the clipper which would have rounded the sharp square edges by removing the harmonic energy.

Most of us are aware of the fact that a square wave is composed of a fundamental frequency and a whole drove (infinite number) of harmonics. Some have waded through the Fourier series analysis, and some can see it intuitively. But if you have never seen it on a scope—even if you have been through Fourier analysis frontward and rearward—you should hook up a simple clipper, followed by a sharp filter that cuts off just above the frequency you are clipping. See Fig. 1 for a sample hookup.

Try this circuit; it is very dramatic. It also serves to illustrate one of the problems with audio speech clipping. The clipped waveform is cleaned up, that is, restored to a single frequency, only if the filter cutoff is relatively close to the frequency being clipped. For instance, if you clip a 200 Hz sine wave, and pass it through a 2 kHz filter, the nice sine wave does not come back. What you get is a mess; now the waveform is still sharp-edged but is usually tilted as well, due to the phase shifts through the filter.

And since the filter for an audio speech system cannot cut off before about 2000 Hz, there is an irreducible problem. Do not despair, however, there is a compromise solution which is well worthwhile. It is possible to have an audio clipper which does not sound bad.

Why do so many sound bad? One reason is obvious. The operator can't stop turning the level knob soon enough—depending on other stations to set clipping levels is haphazard at best.

Some indication can be obtained, however. You know you have gone too far when signals are 10 over 9, you are hearing no QRN/QRM and the other operator keeps asking you to repeat what you said. Many clippers, especially home brew ones, suffer from rf pickup. Rf pickup can destroy an otherwise good clipper. In addition to these problems, the low frequency phase shift/tilt problem is often heard. And finally, some operators using transmitters with sweep tube finals have discovered the tubes were not able to stand the increased duty cycle.

In spite of these caveats, clippers, as well as other forms of speech processing, are becoming more common now. The new all-transistor rigs are as comfortable with 100% duty cycle as they are with 30%, and the FCC has started to meddle with linear amplifiers.

And—are you ready?—The *Handbook* (ARRL) has a graph on page 392 (Figs. 13-20) in the 1977 edition showing 15 dB of audio clipping improves the signal-to-noise ratio by nearly 4 dB. Now you wouldn't build a linear amplifier for a four dB gain, unless you were a CBer, or instructed to by the FCC, but with an audio clipper you can get 4 dB for peanuts. Four dB, just lying around waiting for you to pick it up, like loose change, like found money.

Another goody, but not quite as satisfying as found money, is the text in the 1977 *Handbook* (ARRL) on clipping, clippers, and related subjects. A rather elaborate processor is detailed. It is good to read about, even if you don't build it; in the 60s we called stuff like that mind-expanding.

But enough of that; let's build a clipper. It ought to be simple. It ought to be cheap so some money will be left to build something else. But it ought to sound good. The filter/clipper/filter in Fig. 2 satisfies these objectives.

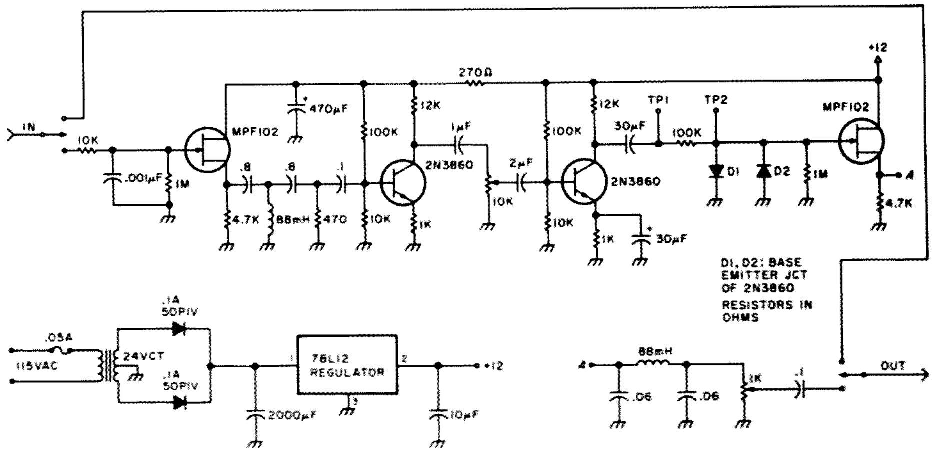

Fig. 2. Audio filter/clipper/filter.

Looking back to address the problems listed above:

1. Rf. The 10k resistor and the .001 capacitor form a low-pass filter which keeps out rf. The 10k resistor could be replaced with a 1 or 2 mH choke, but the 10k resistor is cheaper, and adequate.

2. Low-frequency square waves and tilt. This problem is addressed by using low-frequency rolloff. All frequencies below 500 Hz can be greatly attenuated or even eliminated. The first MPF 102 source-follower feeds a T-section high-pass filter which attenuates the low frequencies, before clipping.

3. Tweaky fingers, or Oops! My plates just melted. The prototype has no knobs on the outside. Knobs on the outside are OK, if you can restrain yourself. Otherwise, you are better off to set it and forget it. Use a scope.

Additional notes: TP1 and TP2 are used with a scope to initially set the clipper. You can set it for whatever clipping level you want, up to the power supply voltage limitations. Eight volts p-p at TP1 sounds good. D1 and D2 are silicon junctions, so the level at TP2 will always be about 1.2 volts p-p. However, it is interesting to look at this point anyway.

The second MPF 102 source-follower feeds the low-pass filter. Output level is set with the 1k pot. A DPDT switch is included for those people who feel insecure if they can't do a regular comparison with distant operators.

My filter is used maritime mobile, and I find it a lot easier to carry around than a linear amplifier. It is very handy when running phone patches for the crew; I can tolerate the screamers and the whisperers—without external knobs. It's not as effective as a 2 kW linear amplifier, but it's a lot easier to pack into my suitcase.■

Fig. 3. The location of slide switch.

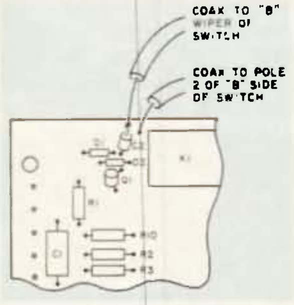

Fig. 4. Corner of top side of control board showing location of C2 and coax cable connections.

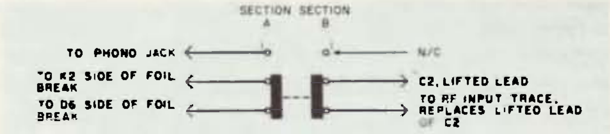

Fig. 6. The wiring of DPDT switch, placed in the T/R position.

source.

Speaking of the external voltage source to energize K2, where do we find it? If you are using the Argonaut, Model 509, the answer is easy—from the accessory jack on the back of the 509. Pin 2 of the accessory jack accesses a lit-

9.3 V dc, but I found that adequate to energize the relay, and it doesn't seem to strain the exciter. Users of the Argonaut, Model 505, the "PM" series CW transceivers, or other QRP rigs will have to do some more modifying. For the Argonaut, 505, and the "PM" series rigs, an additional reed relay was installed between the mike PTT and ground with the contacts between B+ and a phono jack added to the rear of the set.

As I wrote this up, I realized that there are many other ways to pro-

mod came from a junk box, so it was the cheapest way to go.

The main thing is to completely isolate the COR circuit when operating PTT. I had originally isolated K2 from the rest of the circuit, but the COR still takes ¼ Watt to operate. That's a 10% reduction in power at 2¼ Watts input from the exciter.

For the past year I haven't sounded like I didn't know what to say, nor have I received complaints about a maladjusted VOX. The circuit works great and when

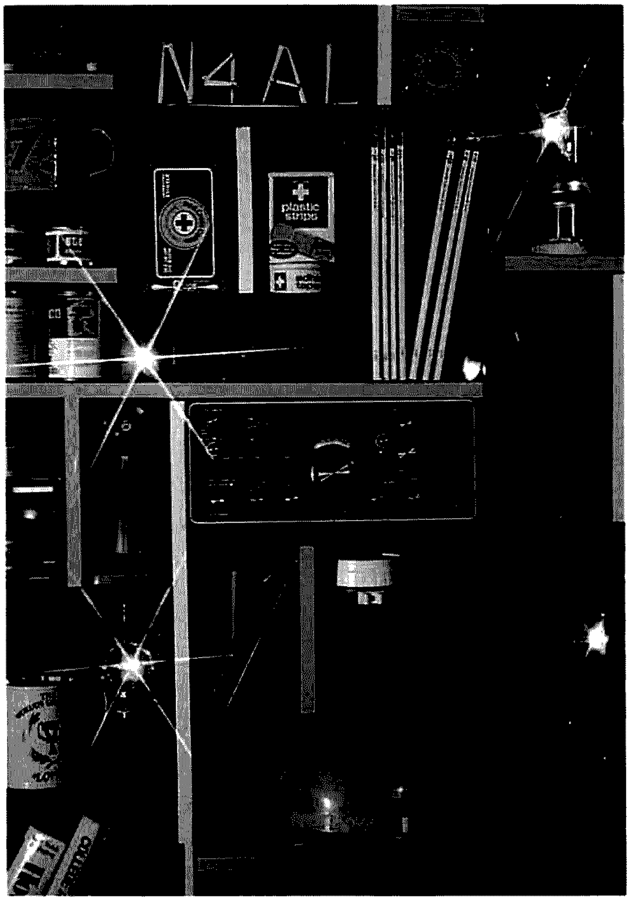
Disaster Preparedness

—it can happen here

Are you ready for a real emergency?

By the second day after the earthquake that devastated most of the cities in Guatemala, it was easy to know where the victims were buried: The smell of decomposing bodies guided the rescue workers. Removing the debris and taking out the corpses was a very painful and grueling job.

Back in Miami, after three days covering the disaster for the *Miami Herald*, I still had the stench deep in my nostrils. As I was looking at the prints coming out of the dryer, memory of the smell gave an added dimension to my thoughts. For a few seconds I believed I was still there, and in my ears I heard the voice of the little girl who sat in the dirt near the field hospital, crying, "Where is Mama? Where is Mama?"



When you are in this kind of situation, you are unable to believe that it could happen in your country, your city, your community . . .

But you are dead wrong, old man . . . This *can* happen to you and to your town, any time, any second. Are you prepared to cope with such a situation?

You are a ham radio operator, and your duty in disaster circumstances is to establish communications in the shortest period of time. That is what amateur radio is all about. We have a responsibility, and we must act accordingly.

Check Equipment

After you read this article, go into your shack and take inventory of your equipment. Then go to the main power switch (yes, the one in the rectangular gray box!) and turn the power off. Back in the shack, find out if you can call a fellow ham in Washington DC and tell him that there was an atomic explosion close to your town and the power plant evaporated with all the personnel inside.

I am not talking about war. An accident can happen. Not long ago, a Russian satellite, with an atomic plant in its guts, landed in northern Canada. Fortunately, the plant did not explode.

On a minor scale, electric power can be knocked out by a tornado, hurricane, earthquake—take your pick of many possibilities. The chance of an emergency is real, and you could be in the middle of it.

Emergency Power

After you find out that you can't establish communications without commercial power, it is time to find another remedy. A small portable electric generator could be the answer. Storage batteries are a cheaper solution and may be more reliable and safe. With a good 12 V dc power supply, you can operate the 2 meter rig to get in contact with local ham radio operators and get organized. With the same battery supply, you can go

airborne in the HF bands, if you are fortunate enough to own a solid-state rig. Long-distance communications are a must in an emergency.

There are a few all-solid-state little rigs for HF on the market, covering ten to eighty meters. Some, like the new Atlas 350-XL, go all the way to 160 meters, with listening capabilities in the WWV frequencies. Ten-Tec also makes a nice all-solid-state little rig, and jumping on the bandwagon are Drake, DenTron, and Alda. The Alda 103 is a three-band rig with battleship construction, capable of taking a lot of punishment.

Of all the rigs, I like Atlas best. Do not make the mistake of believing that the new 350-XL is a deluxe version of the popular 220-X. The 350-XL is a completely different transceiver, with many sophisticated improvements.

But let's stop talking about transceivers and get back to our hypothetical emergency situation with your lack of power.

A gas power plant costs money, and not everybody is ready to invest a lot of dough on something that will be standing by doing nothing but smell. I believe that one or two storage batteries, with 50 or more Ampere-hours, can provide power for a single sideband operation on two meters for the critical early hours after a disaster strikes.

Because storage batteries emit corrosive fumes, it is not wise to keep them indoors. Put them in a wooden box, vented on the sides, sitting on a stand, in the backyard, protected with plastic tiles. Perhaps you could use solar cells to keep them charged. I'll leave that part up to your imagination.

Mobile Equipment

Having mobile transceivers in the car for the HF and VHF bands is an ideal backup for the base station. Actually, the first news relayed to the world of the earthquake that leveled the city of Managua, Nicaragua, was sent by a ham radio operator from his mobile rig. (Enrique Gabuardi YN1EGL). After he and his family escaped from their crumbling home, he went airborne on 20 meters and contacted Adrian Espinosa YN1AEO/W4 in Miami. With tremors of fear in his voice, he told him of the disaster they were witnessing. Espinosa called Rafael Estevez WA4ZZG on the land line. Estevez was the president of SIRA (International Society of Ham Radio Operators).

Gabuardi's faint signal from Managua, from a mobile station, sparked the chain reaction that was translated into a gigantic rescue movement staged by the US Government, the Red Cross, and local and national ham radio organizations. Together with doctors, medicines, food, and clothes, two meter rigs and a group of volunteer Miami radio operators were flown to Managua to help the Nicaraguan hams in the establishment of emergency traffic.

A wounded man is helped by a friend. Thousands lost families, homes, and were injured.

An emergency situation could mean that you, yourself, are forced to leave your home and be relocated in a safe area. In a case like that, you should report

A little girl looks over the rubble which was her home. She does not know where her family may be.

This woman faces a grim future, with her home destroyed and her husband dead.

to the authorities that you are a licensed ham radio operator and can assist with communications. This could facilitate your transportation with your equipment and power source. This is one reason why I emphasize the importance of small solid-state rigs. (Another is that in flood conditions electrical equipment is dangerous, and low-voltage rigs like all-solid-state are safer.)

Disaster Training

Field Days are traditional among amateur radio operators. Every year, clubs and radio organizations all over the country get airborne and compete. But is this the real kind of training we need?

During the last ten years, I have been covering, as a newspaperman, revolutions and major disasters in the Caribbean and Central America. In my trips, I made contact with the local radio amateurs. These experiences taught me that while Field Day operations are a lot of fun, they are not remotely close to conditions one finds in a real situation. Technical skill to establish communications is not enough if you are not adequately prepared.

Preparedness and coordination within local ham clubs and Civil Defense organizations are very important. If you belong to a club which sponsors a repeater, be sure that the technicians in charge have that repeater backed up by storage batteries in case of power failure.

Hurricane and tornado warning notes are important. A well-organized system can save many lives. Mobile operation is a must and if you can work all the bands from your car, that will put you in a favorable position to help your fellow citizens. Another point: Don't risk your own life unnecessarily! You are more useful alive and in one piece.

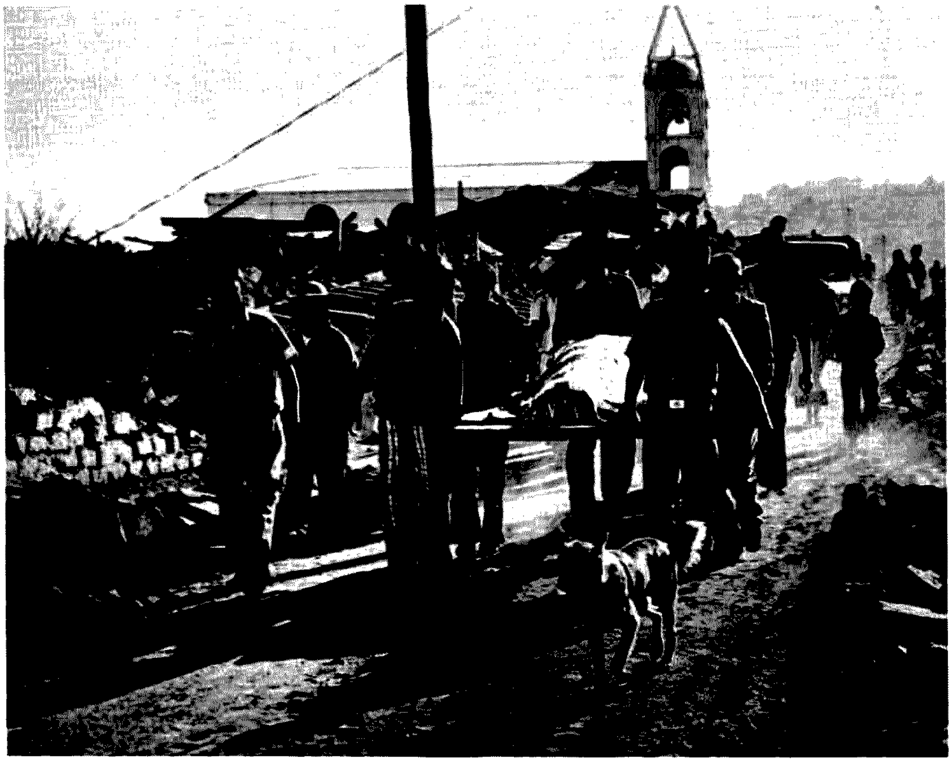
Be Ready Yourself

Finally, provide for your own basic needs. Water contamination and food shortages must be anticipated. Water purifying tablets like Halazone should be on hand. Nonperishable foods, cereal, canned beef, milk, and sugar should be stored at all times for yourself and your family.

First aid articles like cotton, bandages, aspirin, iodine, alcohol, and other standard items should be stored in a box for easy access and transportation. Good first aid kits can be purchased at any drug store.

Take your immunization shots regularly and keep your certificate on hand. This will give you clearance with the authorities to move around with freedom. It is a good idea to take courses in first aid and rescue operations with the local Red Cross. Try to stay in good physical shape. Remember that a good pair of legs can save your life when everything collapses around you.

Good luck, and 73! ■

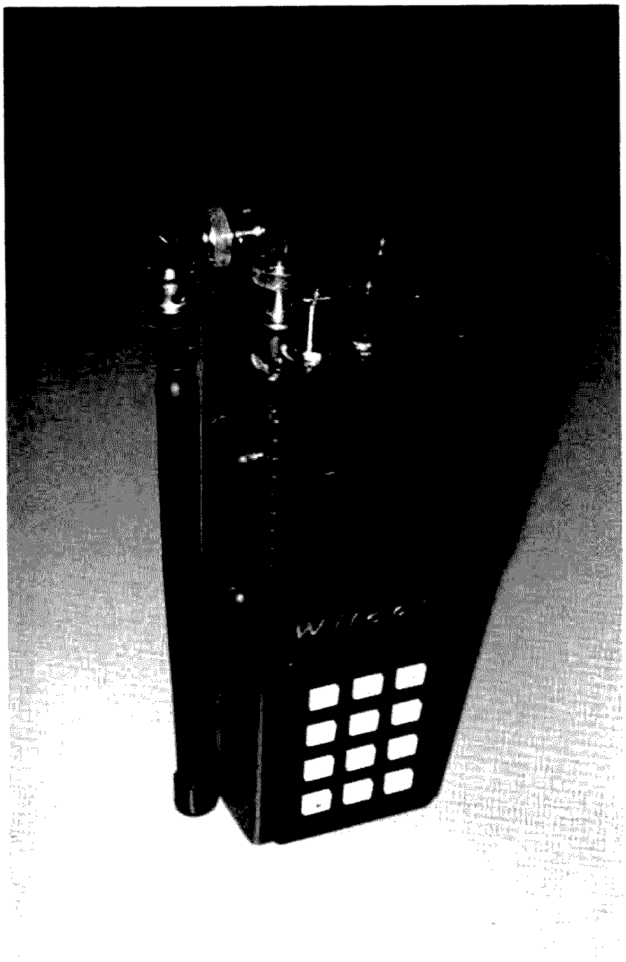


The dead can't wait to be buried. In San Pedro, Guatemala, where thousands were killed, there wasn't a single home spared from destruction.

Comfort Mods for the Mark II

—invert your duck

The latest in armpit safety.



Lewis Dickson WA4HUZ
1814 Hidden Glen Dr.
Marietta GA 30067

Recently I became the proud owner of one of Wilson's latest innovations, the Mark II. This new hand-held is quite compact, light, and easy to carry.

I have included a couple of features on my rig I feel make it more versatile and easy to handle.

First, I have added a belt clip to the back of the unit. The best clip I have found is by Motorola. It matches the color and texture of the plastic of the Wilson case exactly. The only way I have been able to get this clip is by ordering the complete back with clip for the HT220 from Motorola. It is part number NLN6675A and costs $9.63. (It has the big Motorola "M" on it, but just look at it as a "W" upside down.)

Installation is easy—just drill two small holes near the top of the battery cover and attach the clip with two screws.

Second, I made an addition at the antenna. When carrying hand-held rigs that are restricted to rubber ducky antennas on your belt, the ducky tends to get stuck under your armpit. To avoid this uncomfortable experience, I added two 90° BNC connectors. This allows the rubber ducky to be swiveled down alongside the rig out of the way. Granted, this is not the most ideal position for such a high gain antenna for DX work, but it's good around a hamfest to monitor for your buddies to call and even to transmit short distances or listen to nearby repeaters. When you need to work DX, just swivel the antenna into the up position.

I took my modified Mark II to the Atlanta hamfest and was stopped several times by people inquiring about the antenna arrangement. When I returned to the hamfest the next day, I noticed half a dozen people with "bent" rubber duckies on their Wilsons. ■

An 8080 Repeater Control System

—part III: software

The finishing touches.

A development system is necessary to write and debug a program of the size and complexity of that of the repeater control. There are commercial development systems available, and hams lucky enough to have access to these systems have the opportunity to modify the program presented here with ease. Medium-to-large-size hobby computers are also equal to the task. I used my personal homemade computer for development. It has 60K of read/write memory, a high level operating system including a text editor and assembler, printer, debugging tools, and the capability to program 2708s. The processor itself is an 8080, so I was able to actually execute the repeater program on it before burning it into ROM.

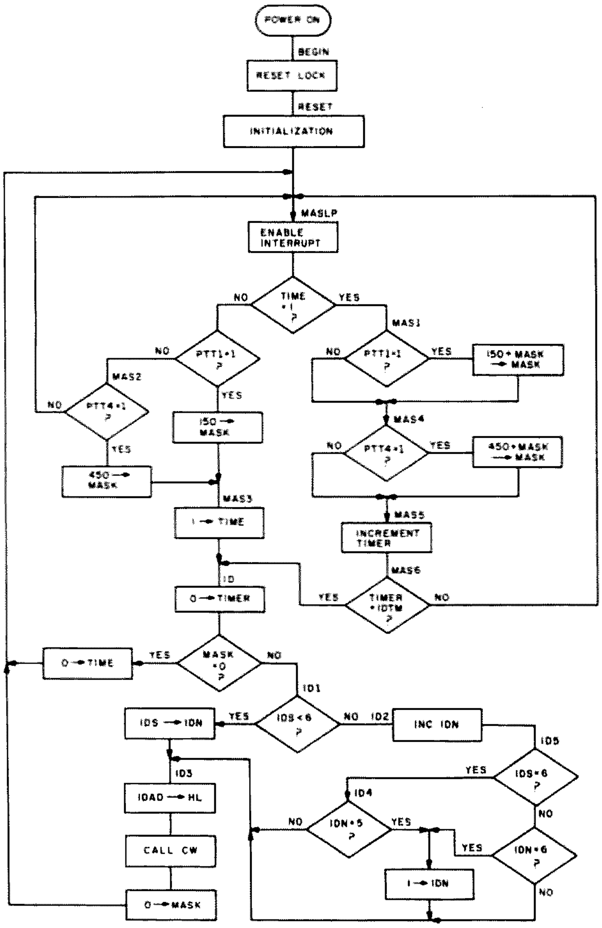

Fig. 1. Foreground program.

A good development system is a must when starting from scratch, but if the program is to be used as presented with only code changes, most any hobby computer can be made to program the ROMs. Major modifications would necessitate reassembly.

Program Analysis

The repeater control program is fairly long and it may appear quite complicated at first glance. Everything is broken down into manageable subroutines, so it is not too difficult to follow program flow. The software consists of two programs: the foreground program and the interrupt program. The two programs are separate and operate independently. The foreground program counts time, and when it is time for an identification, it performs the CW ID. Touchtones™ interrupt the processor, and control is passed to the interrupt program (which performs whatever task is required). The foreground program may be interrupted at any time, and when the interrupt service routine exits, control returns to the foreground program at the point where it left. This is apparent when listening to the repeater. If the repeater is identifying, and a touchtone is sent, the ID halts, and, after the tones are handled, the ID resumes where it left off. The beauty of the scheme is that the interaction of the programs is handled entirely by the interrupt hardware.

Foreground Program

Refer to the program listing. At the beginning, some labels are defined. The various ports are set equal to the proper values. CWSPD sets the speed of the CW. At its present setting, the speed is 19 wpm. The CW speed should be proportional to CWSPD. IDTM0 through IDTM3 set the time duration between successive IDs. This is currently set at three minutes.

When the 8080 is reset, it begins executing com-

mands at address 0. Refer to Fig. 1, a flowchart of the foreground program. At BEGIN, a lock is cleared. The lock permits the removal of the ability to enter the control mode. This will be explained in detail later. Control passes to RESET, where all variables are initialized. All of the output ports are zeroed. A note is in order about how the program handles output. The 8080 can output to its output ports, but it cannot read its output ports back in. Since we need the ability to be able to change only one bit at a time in the output ports, a memory byte is reserved for each output port. Every time the processor outputs data, it writes the output information in the locations OUT0M through OUT7M for ports 0 through 7. This way, if an output bit needs to be changed, the corresponding memory location can be read, the one bit changed, and the byte output. All bits of port 7 are set, because the row and column inputs to the touchtone generator are active low. The stack pointer is loaded, and control jumps around the interrupt location to MASLP.

At MASLP (master loop) the interrupt is enabled, and TIME is checked. If TIME is 0, the system is in the rest mode; as soon as a repeater is used, it will ID. When TIME is 1, the system is counting time to see if it is time to ID. In the program, if TIME is 0, the 150 PTT is checked to see if the repeater is in use. If not, the 450 PTT is checked at MAS2. If neither repeater is in use, the program loops around, continuously waiting for one to be used. When a repeater is activated, either a 150 code or a 450 code is put into MASK. MASK is a variable which tells the CW sending program which repeater to ID. At MAS3, TIME is made 1, and control goes to ID. At ID, TIMER is zeroed. TIMER is a four-byte counter, used to time up to three minutes. The repeater identifies, but before explaining how that occurs, the other path to ID will be explained.

At MASLP, if TIME is 1, control passes to MAS1. In this portion of the loop, the repeater has identified sometime in the past three minutes. In the subsequent three minutes, the processor keeps tab on the repeaters to see which ones should ID later. At MAS1, MASK is modified to reflect which repeaters are in use. TIMER is incremented, and, at MAS6, TIMER is checked to see if it equals IDTM (ID time). If not, three minutes have not elapsed, and the program loops back to MASLP. When time is up, control passes to ID, as before.

At ID, after TIMER is zeroed, MASK is checked to see if either repeater has been utilized in the last three minutes. If not, control resumes at MASLP after clearing TIME, placing the system back into the idle condition. If a repeater has been used, control goes to ID1. At this point, it must be determined which ID message is to be used. IDS (ID status) may have values from 1 to 7. 1 through 5 specify that that ID number is to be used, 6 indicates that the first four should be cycled, and 7 indicates that all five should be cycled. IDN (ID number) specifies the current ID number. IDN goes from 1 to 5. If IDS is between 1 and 5, IDN is set to IDS and control goes to ID3. At ID1, if IDS is 6 or 7, control goes to ID2 where IDN is incremented, advancing to the next ID message. At ID4 and ID5, IDN is checked to see if it is greater than it should be, and if so, it is set back to 1, and control goes to ID3.

At ID3, the HL registers are set to the address of the proper ID message, and the CW sending program is called. After sending the ID, MASK is zeroed and control goes to MASLP.

The CW sending routine is shown in Fig. 2. It is assumed that the address of the message to be sent in CW is in the HL registers, and that MASK indicates which repeaters to send the message to. If the destination is 150, MASK contains C0; if the destination is 450,

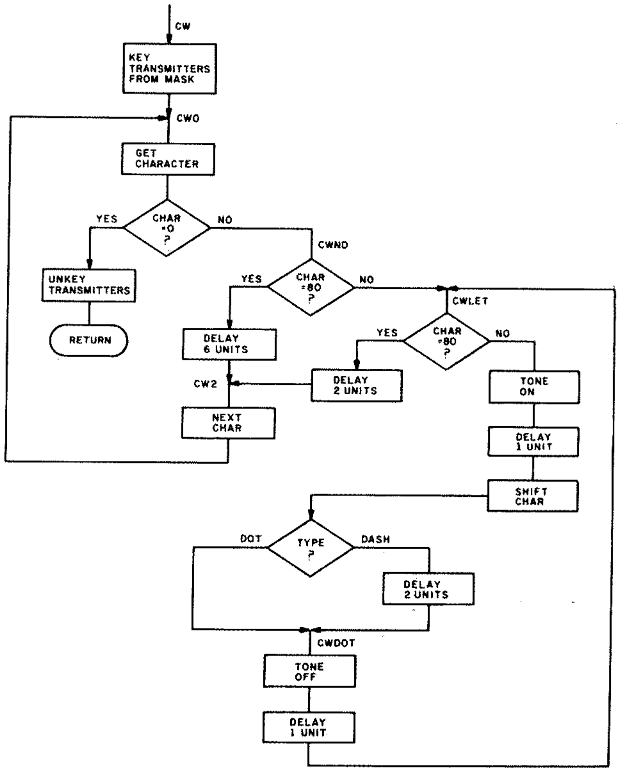

Fig. 2. CW routine.

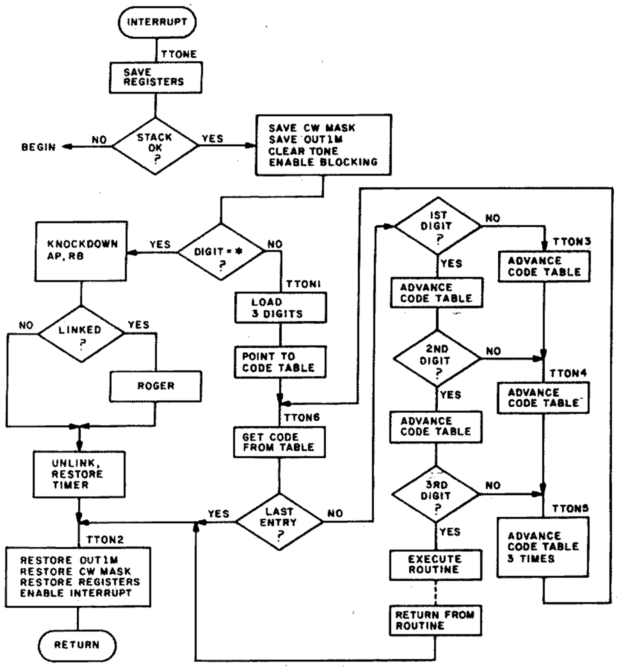

Fig. 3. Interrupt service routine.

MASK contains 30; if the destination is both, MASK contains F0. On entry, the proper transmitters are keyed, keeping them on the air for the duration of the message. At CW0, the character to be sent is fetched. A zero byte indicates that the message is done. If done, the transmitters are unkeyed, and the subroutine returns. Otherwise, at CWND (CW not done), the character is checked to see if it is the special space code of 80. If so, a 6-unit delay is made. A 1-unit delay is appended to every character, so a space is a total of 7 units long. If the character is not the special space code, control goes to CWLET (CW letter). Morse characters are stored left justified, with a 0 representing a dit and a 1 a dah. The byte is shifted left after each dit or dah, and when the byte ends up at 80, the character is done (described in *Byte*, October, 1976, page 36). After CWLET, the tone is turned on. If the character is a dah, an additional delay of 2 units is appended. At CWDOT, the tone is removed, and a trailing 1-unit space is added. The routine loops back to CWLET until the character is finished, where 2 more units are added to create a 3-unit intercharacter delay. At CW2, the next character is fetched and control loops back to CW0. The CW routine is used both by the ID section of the foreground program and various routines in the control section.

The Interrupt Service Program

The interrupt routine is shown in Fig. 3. When the 8080 is interrupted, it goes to address 38. It jumps to TTONE (touchtone), where the service routine is located. Since the foreground program may be interrupted at any time, it is necessary to save all registers. As an error-recovery technique, the stack pointer is checked to see if it is in the limited address space where RAM is located. If not, something is awry, and the program jumps to the beginning, resetting everything. If the stack is okay, MASK is saved, since it may need to be modified by the interrupt programs. OUT1M is saved because some bits are changed there as well. The CW tones are killed, in case an ID has been interrupted (which could leave a constant tone on the repeater until return to the foreground program), and BLK is set high, enabling the blocking function. The decoder is checked to see if the digit is a *, the knockdown digit. If so, the KD output is pulsed for about a millisecond to kill any possible autopatch or remote-base function. If the repeaters are linked, the routine ROGER is called, which sends the "R" in CW. The repeaters are unlinked, and the timeout timer is placed into the timing mode in case a single-digit autopatch was in progress. Control goes to TTON2, the exit point.

If the incoming digit is not a *, LOAD is called, which gets a three-digit code. The code table is checked for the three-digit code. If the code is not found in the table, control goes to TTON2, and nothing happens. If the code is found in the code table, the address of the routine to execute that particular code is obtained. At that point, the program jumps to the particular routine. After the routine is executed, control jumps to

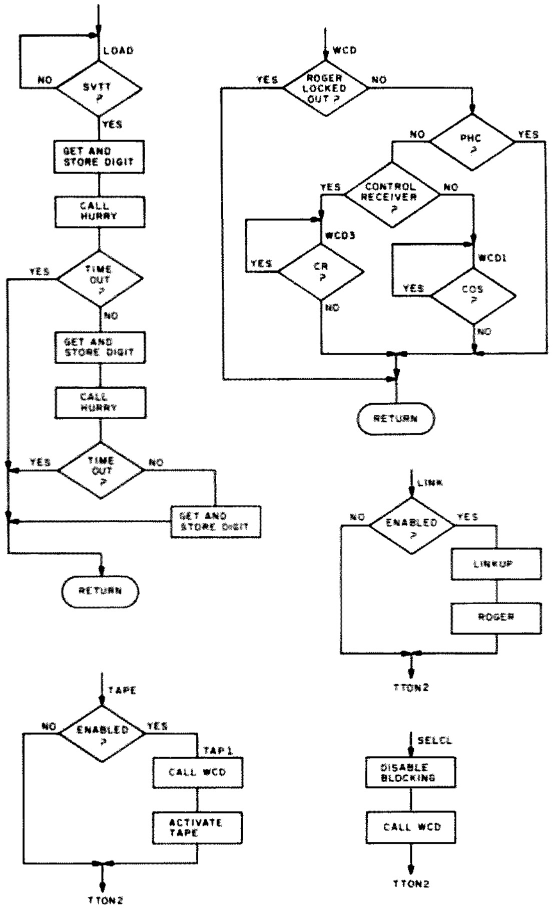

Fig. 4. Load, wait for carrier drop, link, tape, and selective call routines.

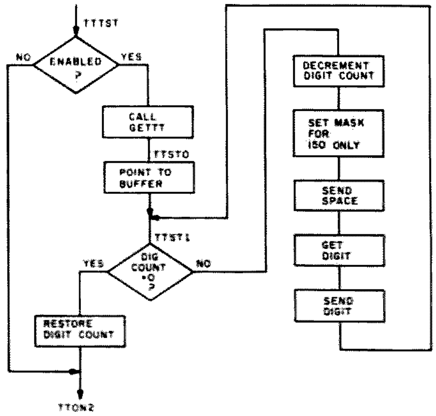

Fig. 5. Touchtone test routine.

TTON2.

At TTON2, everything that was saved upon entry of TTONE is restored and the interrupt routine returns to the foreground program.

BITS is a bit set routine used to set a bit in an output byte. The address of the byte is placed in register DE, and a 1 is placed in the desired bit in register B. BITC clears bits the same as BITS sets them.

Shown in Fig. 4, LOAD gets a three-digit code from the touchtone decoder. Upon entry, LOAD waits for SVTT. For user codes, SVTT is immediately present, since it is SVTT which caused the interrupt. For control codes, where several three-digit codes are used, LOAD waits for a code to be entered. When a digit is ready, LOAD calls DECOD. DECOD reads the input ports and decodes the digits into binary form. The digit is stored, and HURRY is called. HURRY checks VTT while counting time. If a tone occurs before three seconds elapse, HURRY returns with the carry clear. If no tone is received in three seconds, HURRY exits with the carry set. The timeout is detected in LOAD, the program is aborted, and LOAD returns. Otherwise DECOD gets the next digit, the sequence repeating. The third digit is fetched in the same manner. After exiting LOAD, either three digits are stored or an invalid code is stored because of failure to send successive digits within three seconds.

DECOD reads the decoder. Presumably, a tone is present when DECOD is called. The digits 1 through 9 are stored as those numbers, and 0, *, and # are stored as decimal 10, 11, and 12. A digit stored as 0 indicates an invalid code. LOAD presets the three digits to 0, so timing out results in one or more stored digits remaining 0

The routine WCD is used to wait for a carrier drop. It is possible to lock out the ROGER routine. If this is done, it also eliminates the need to wait for dropping carrier when controlling the repeater. Upon entry, WCD checks for this, and normally proceeds to check to see if it is in the phone control mode. If so, WCD returns. If not, it checks to see if the control receiver is being used. If so, it waits for the signal there to drop. If not, it waits for the COS signal to disappear. In this manner, WCD only waits when necessary, and waits for the proper signal. The LINK routine checks if the function is to be permitted. If so, it links the repeaters and calls ROGER.

The TAPE routine checks to see if the function is enabled, calls WCD, activates the tape, and exits.

The SELCL (selective call) routine clears BLK, calls WCD, and exits. This permits any tones after 3#3 and before the carrier drop to pass.

TTTST, the touchtone test routine, is shown in Fig. 5. If the function is enabled, GETTT (get touchtone) is called, which loads a sequence of digits. Control goes to TTST1, where the digit count is checked. For each digit, the digit is converted to CW and sent. The addresses of the CW conversions are at DIGAD. The actual CW codes are at CWD1 through CWDP. After the buffer is sent, the digit count is restored and TTTST exits.

The GETTT routine is shown in Fig. 6. Upon entry, the digit count is cleared and register pair DE is initialized to the start of the buffer. If carrier is present at GETT1, the VTT is checked. The program loops until either the carrier is dropped or a digit is received. When the latter happens, DECOD is called and the digit is placed into the buffer. The digit count is incremented, and checked to see if the buffer is full. The buffer is loaded in this manner until the carrier is dropped, when GETTT returns. If the buffer length reaches maximum, WCD is called and then GETTT returns.

When the three-digit control code is sent, the program goes to CNTRL, shown in Fig. 7. If the control mode is locked out, CNTRL exits immediately. Otherwise, WCD is called, and then LOAD. The HL registers are

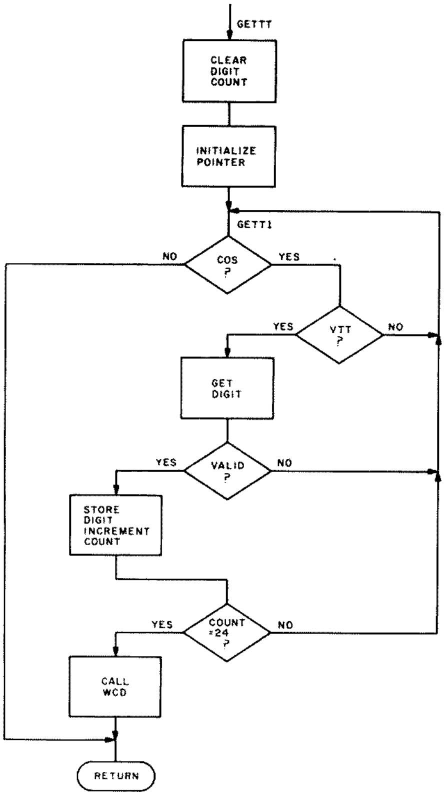

Fig. 6. Get touchtone routine.

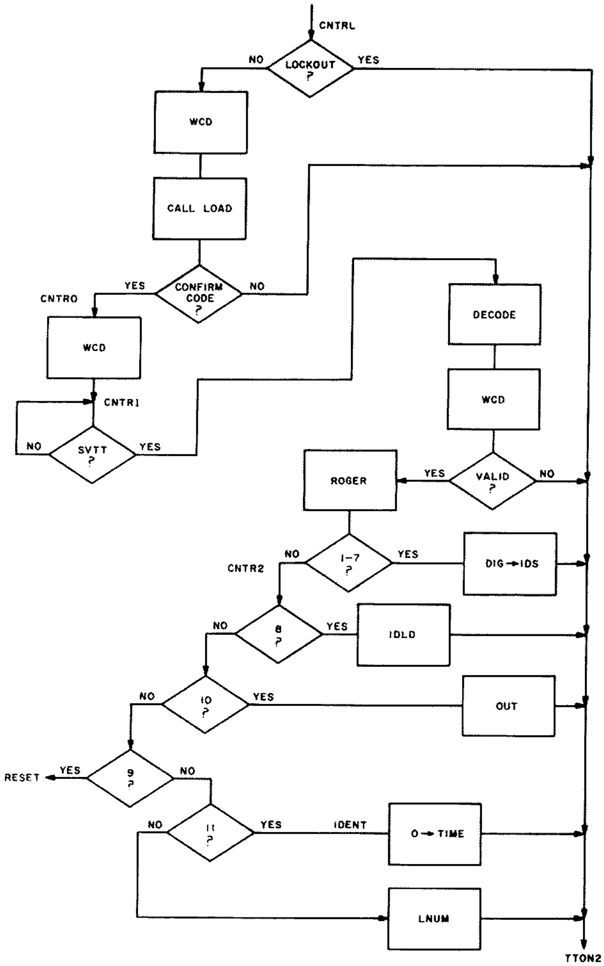

Fig. 7. Control routine.

loaded with the address of the confirm code. Jumping to TTON6 enters TTONE at a point where the code received is checked against the code table, now consisting only of the confirm code. If the received code is not in the single entry table, the interrupt is aborted as usual. If agreement is found, TTONE sends control to CNTR0, a continuation of CNTRL. WCD is called, and CNTRL then loops at CNTR1 until a tone is received. A single-digit code is expected, and DECOD is called to get it. WCD is again called, and if the received digit is invalid, control exits. Otherwise, ROGER is called and the proper program must be selected. If the received digit is between 1 and 7, IDS is loaded with that digit. The command is done, and CNTRL exits. If the digit is 8, CNTRL jumps to IDLD (ID load). A 10, which is digit 0, sends CNTRL to OUT, and 9 has the program jump to RESET, initializing the entire program with the exception of LOCK. If the digit is a *, TIME is cleared; otherwise, the digit must be a # and CNTRL jumps to LNUM (load number). Each routine, at completion, goes to TTON2 and exits.

Fig. 8 shows IDLD. The HL registers are loaded with the address of the programmable ID. The character byte in register B and element count in register C are cleared at IDLD0. IDLD1 waits for a digit to be received, and DECOD is called. If the digit is 3, the stop byte is stored, ROGER is called, and IDLD exits. Otherwise, control goes to IDNTS (ID not stop), where the digit is checked to see if it is a 2. If so, at IDDLT (ID done, left justify) register B is justified by the element count in register C. The character is stored in the message buffer at IDDL (ID done letter), HL is incremented, and control loops to IDLD0. If the digit is not a 2, it is checked to see if it is a 1. If it is, a 1 is shifted into register B and the element bit count is incremented. Otherwise, the digit is checked to see if it is a 0, where a 0 is shifted in. If the digit is not a 3, 2, 1, or a 0, then an invalid digit was sent and it is ignored.

The OUT routine, in Fig. 9, outputs selected bits to the output ports. LOAD is called to get a three-digit code. If the first digit is a *, ROGER is called and OUT exits. Otherwise, the digits are checked to see if they are 0, which is invalid. If an invalid entry is made, after carrier drop, control loops back to OUT. If port 0 is selected, the 10 is changed to a 0 for later use. Several validity checks are made, checking to see if port, bit numbers, and output levels make sense. If they do, ROGER is called. At OUT2, the binary code for the bit number is converted to a 1 in the proper bit of register E. At OPRT (output to port), a machine output instruction is set up in RAM with the required port number. The bit is either set or cleared, and the output instruction in RAM is called. Control loops to OUT, and the cycle continues until OUT is exited with a *.

LNUM (load number) is shown in Fig. 10. The digit count is zeroed, and at LNUM1 LNUM waits for a received digit. DECOD is called, and if the digit is a *, ROGER is called and the routine exits. Otherwise, the digit count is checked and the digit is stored. If more than 11 digits are attempted, the last digit keeps being overwritten.

LOCK has two functions.

```

Program listing.

It can block access to the control mode, and it can eliminate the ROGER routine. After the LOCK sequence is given, LOAD is called to get three digits. The second digit eliminates the ROGER routine if it is a 1, and the third digit locks the control mode out if it is a 1. ROGER is then called, and LOCK exits. If the second or third digits of a LOCK command are 0, the normal state of the appropriate function is resumed. The LOCK function is intended as a fail-safe measure, available only to the person who constructs the system. The reset instruction (9) is purposely constructed so that it does not reset LCKR, the locker

where the control mode may be inhibited.

PATCH, the autopatch routine, is one of the more complicated subprograms. Shown in Fig. 11, PATCH first checks to see if the autopatch is enabled. NOTIM (no timer) is cleared so that the timer will be present unless changed later. GETTT gets the requested telephone number. The digit count is then checked. If no number was sent, and a direct autopatch is allowed, then at PTCH1 AP is pulsed, giving the user the line to dial his own number. Otherwise, the attempt is aborted. If 7 digits were entered, control passes through PTCH2 to PTCH8. If the first digit of the number is a 1, the patch is aborted. If not, at PTCH3 AP is pulsed, bringing up the line. At PTCH5, a one-second delay is introduced to allow time for the telephone company equipment to produce the dial tone.

Our exchange is an electronic switching system and is very rapid. If it commonly takes longer than one second at your exchange, change the number 15 to a larger number in line #1057. A 1 is sent to the LD output, preparing to dial the number. At PTCH6, the number is dialed. Each tone is on for 65 ms and off for 65 ms, the time DELAY waits. The binary digit numbers are converted to the proper row and column format by the TTTAB (touchtone table). When the number is completed, LD is turned off, and if NOTIM is not 0, the timer is disabled. Similarly, if 8 or 11 digits are requested and the first digit is a 0, the same procedure applies. If a single-digit number is requested, a table is searched at PCH10. The single digit table, SDTAB, has the single digit followed by the address of the corresponding telephone number. At the loca-

tion of the number, the number of digits precedes the actual number, permitting any digit length. A 0 must be stored as a decimal 10. If the number is not found, PATCH exits. If found, the digit count is checked, primarily for the programmable number. If the number is valid, the telephone number is copied into the GETTT buffer, NOTIM is set, and control goes to PTCH3, where the rest is normal.

The remote base routine, RBASE, merely pulses RB. TAP2, the secondary tape access, jumps to the appropriate point in TAPE. DIAL, the 5#5 function, makes various checks and jumps to TTTST at a point where the existing buffer is sent.

The two ROMs are set up in a fashion to permit as many changes as possible in the second ROM without requiring a replacement of the first ROM as well. Most

forward references from the lower ROM go to the beginning of the second ROM, which will not change if a routine in the second ROM is modified. Frequent use is made of reading an address from a fixed location rather than reading an address directly.

The code table is organized with a three-digit code preceding the address of the program to service that code. The end of the table is marked with a 0. Naturally, the published codes are not the ones in use. The CW ID messages are set up with leading and trailing spaces to clean up the ID.

The RAM has the bottom 25 bytes reserved for the digit buffer, including one for the buffer length. 12 bytes are reserved above that for the digit #1 telephone number. Above that, space is left for the programmable ID. 22 bytes at the top are variables, and

the stack starts below them. The stack works down, and the programmable ID works up. No safeguards are set up to eliminate the two clashing. The amount of space is so large for the required functions that for even the longest imaginable ID message there will be plenty of room left for the stack. I do not suggest testing the system by loading an ID of 197 characters! Up to 150 should be safe. OUT0M is a dummy output port. Although it is set up as an output port, there is no physical port. This is convenient for both programming and operation.

Design Philosophy

As previously mentioned, several years ago I had constructed a microprocessor system to perform a similar

function. At that time, I built the hardware first. After completing this project, I have no doubt that the proper procedure is the other way around. A general idea of the hardware should be in mind, but the program should be written first. Writing the program defines the parameters of the system. By doing so, I found that some hardware modifications were needed that otherwise I would have had to go back and redo.

The program was written and debugged on the development system described. I configured the I/O ports so that the program could be executed on my large system. The program was in operation on it before a single wire was cut to construct the hardware. Clip leads and external oscillators were used to test the system. Did you ever try to simulate touchtones with clip leads, trying not to be caught by a three-second timer?

The program was modularized as much as possible. If any routine is longer than about two or three pages, it is too long and should be broken down into smaller routines. Not only is it easier to write that way, but it is also easier to understand how it works a few months later. For routines with many conditionals, flowcharts are a must. Originally, a skeleton program was written—just enough so that the entire program was self-consistent. Gradually the individual routines can be added to the code table and debugged. The throughput using these techniques can be quite high. I wrote the skeleton program in one day, and debugged it the next. Once an operational program was ready, the hardware was constructed. In the week or so it took to build the thing, the program was beefed up. By the time the hardware was ready, the software was refined. I cannot overemphasize the fact that a 100% operational program is necessary before building the hardware. When the ROMs are plugged in, if the program is in any doubt, and the system does not work, you do not know if the problem is hardware or software, resulting in an exercise in futility.

The hardware/software tradeoffs previously mentioned are important. A lot of thought is necessary before plunging ahead with design. The total software and hardware development time/cost must be considered. Even though the individual pays nothing for his own software, thinking like the businessman who must pay for his software will give a more balanced design.

When building hardware, it is advantageous to freely add LEDs on signal lines. You may not need them after the circuitry is in operation, but they are invaluable when debugging and testing the system. Design a system that not only works properly, but also can be made to operate properly in a reasonable amount of time.

Fault tolerance is an area at the frontier of theoretical knowledge. The discipline is about a decade old, and much remains to be worked out satisfactorily. Semiconductor technology is increasing at a rate which is hard to keep up with. Writing programs which merely function, and programs which both function and are error-tolerant, are two different things. Instead of making equivalence tests, it is better to make relational tests. Otherwise, if an error occurs, a test may fall through. Subprograms are usually expected to be entered with certain initial conditions. They should be constructed so that if those conditions are erroneous, the subprogram will exit soon. The worst thing that can happen is an erroneous input condition resulting in an endless loop. In a controller, it may not be as easy to push the reset button when something goes awry as it is on a general-purpose computer. I certainly did not follow all of these tenets in writing the software; however, I attempted to keep them in mind as much as possible.

The original program, somehow, did manage to crash twice. After that, I added the error recovery portion. It is a very simple, first-order attack, but it covers more errors than a first glance shows. If the program gets into a false state, it will often go to a faulty address. Since the hardware uses a small amount of the address space, it is quite likely that the program will be sent to

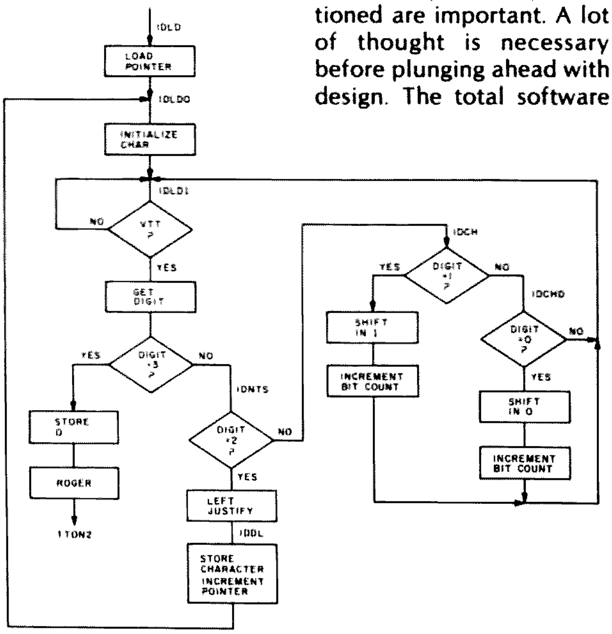

Fig. 8. ID load routine.

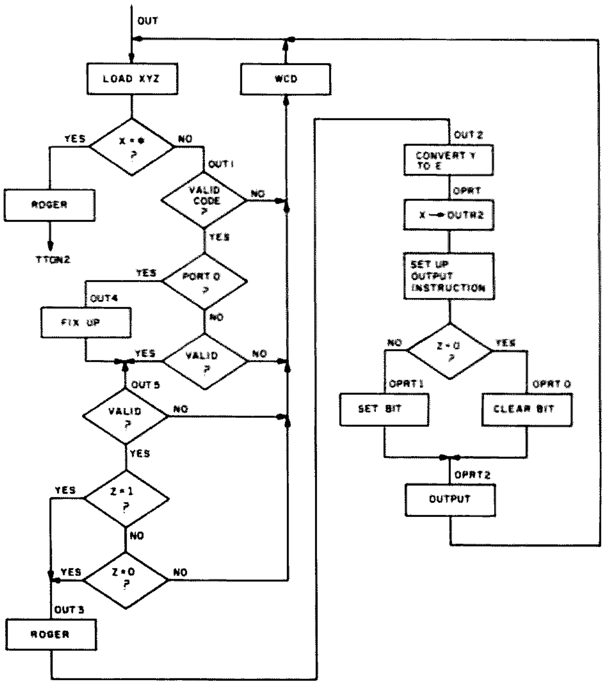

Fig. 9. Out routine.

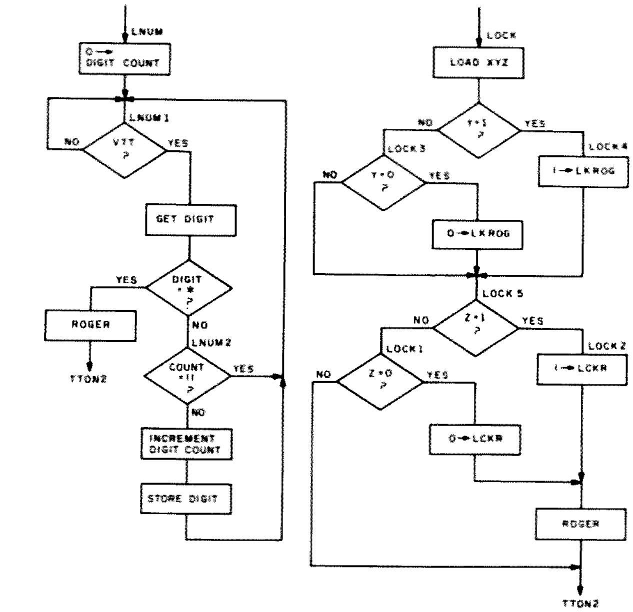

Fig. 10. Load number and lock routines.

a place where there is no memory. This results in reading all highs; the instruction FF is the interrupt instruction, so effectively an invalid memory address interrupts the program. That is why I placed the recovery routine at the interrupt location. The processor is not being interrupted, but it interprets the error as an interrupt. A second different thing about the fault-tolerant program is that the enable interrupt instruction was placed into the master loop. Otherwise, if the interrupt were ever disabled when in the foreground program, there would be no way to communicate with it.

I am not claiming that the system is totally fault-tolerant, but by the addition of some very simple checks, the fault tolerance can be increased tremendously. This entire project has been a good education.

Expansion

There are many additions and improvements which can be made. The advantage of the whole arrangement is that for many changes, hardware need not be touched. Many functions can be added by software changes only. It is more pleasant to sit in an easy chair at home rewriting the program than to sit on the cold, hard floor at the repeater site to effect changes. If changes don't work, all that has to be done is to put the original ROMs back in.

Additional hardware can be added to mate with the existing circuitry, and it is not necessary to worry about the additional control functions, as plenty of spares are already provided. A possible improvement to the software would allow interrogation of the status bits. This is a simple addition which is not required but might be useful. A planned hardware addition to the system will provide downlink telemetry from the site. Lights on the voting selector indicate which receivers are being accessed, and which receiver the voter selects. The telemetry will transmit the voter lights in real-time. Incorporated in the telemetry package will be an analog-to-digital converter. Upon command from the control system, the telemetry will switch from the voter lights to

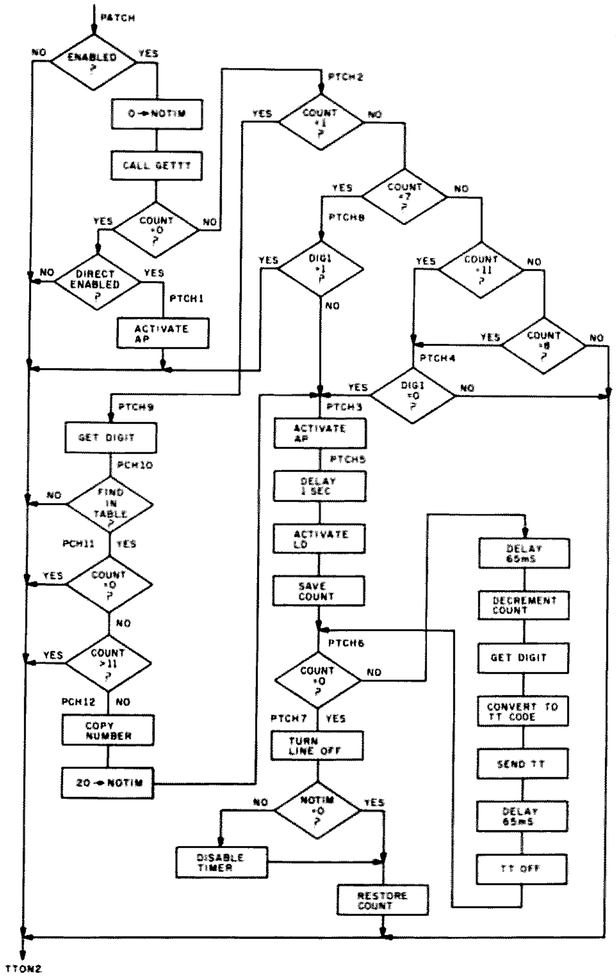

Fig. 11. Autopatch routine.

meter readings read by the A/D; plate voltage, plate and grid current for each repeater, and cabinet temperature could be read. With the existing central control system, the possibilities for expansion are straightforward and exciting.

Acknowledgements

I would like to thank Carroll Van Ness K3HZU for his able assistance in designing the autopatch circuitry. Until this time, Carroll has been the father of the control circuitry and the autopatch. His equipment always functioned fine, but there is only so much that can be done with relays. Carroll is now a microcomputer convert.

I received help from Vern Chapin K3VC with the metalwork. Despite broken saw blades and bruised fingers, he finished the panels.

I thank Frank Ayd WA3ILR, who stayed with me over 13 hours at the site on the day of installation. We were both dirty, tired, cold, and hungry, but he remained with me while making frantic pleas that we quit.

Thanks go again to Vern Chapin K3VC, and also to Marc Leavey, M.D., WA3AJR, for their photography.

And if not for Jack Biggs K3SP and Larry D'Anna WA3KOK, with the assistance of many others over a period of several years, I would not have had the excellent repeater for which to develop the control system.■

The Micro Duper

—for small contests

The January VHF Sweepstakes is a very popular contest. It brings out operation on the VHF frequencies that usually does not exist at other times. In fact, anyone with a modest setup capable of 100 Watts on CW and SSB with a beam of 11 elements or better can make hundreds of contacts during this weekend on one band alone. Since I am equipped with just a TS-700A and 16 elements at 50 feet, I decided to try my luck on two meters.

A few glasses of wine later, my wife, Chris WA2KOU, and Bill WA2RZR became more interested in coming up with a computer dupe sheet for the contest than operating the contest itself. The computer system is the Heath H8/H9. The program calls for the operator to enter the call of the station. The computer will then ask if you have entered the call correctly in order to prevent typing mistakes. Upon answering with a "Y" for "yes," the computer will then ask if you wish to have the station logged into memory. This was placed into the program to allow the contest operator the opportunity to work (or try to work) that particular station. If you work that station and answer "Y" to the last computer question, the program logs that call and returns to the beginning.

If you answer "N" for "no" to the computer question "Do you have the call correct?", the computer will return again to the begnning and ask for another call to check.

In the event that you enter a call that has already been worked and logged, the computer will respond with "DUPE - DUPE - DUPE - DUPE - DUPE" or any other obscenity you wish to include and then return with a question for the next call. A sample of the program is shown in Fig. 1.

As can be seen, Fig. 1 is a rather simple program and can be expanded to include such things as different bands, etc. But the main purpose was to have an easy dupe sheet for the minimum amount of time and energy, and the maximum amount of glasses of wine. It works well, and it does not take much time to run in between contacts. If you make it too complex, it may take time away from hunting down the points. The program listing for this little gem is shown in Fig. 2. Good luck, and I'd like to hear about any changes.■

```

Fig. 2. Program listing. Please note that, in statement 15, the number of contacts that the program will keep track of is 250, but can be changed by altering the number within the parentheses.

An 8080 Disassembler

—written in BASIC, yet!

Convenience plus.

Jef Raskin
586 Eighth St.
Montara CA 94037

This program was written for a Poly-88 microcomputer. However, since it is in BASIC, it is easily modified for other 8080-based computers that have a BASIC interpreter or compiler available.

A disassembler's task is very difficult. It must be able to jump into the middle of the computer's memory, help the user to read the mixture of ASCII and numerical data stored there, and change the numerical instruction codes into mnemonic assembler code. Instructions on the 8080 are of variable length, and if the disassembler happens to start ih the middle of an instruction rather than at its beginning, what comes out is garbage.

To help cure these problems, this disassembler displays the contents of each location in hexadecimal, in ASCII, and in assembler code. It takes into account the variable length of the instructions. The misalignment problem is quite difficult, and if the disassembler is started in the middle of an instruction, it usually takes a few instructions before it is back on the track. However, this program incorporates a heuristic method for obtaining correct alignment. A special code "P", for "Previous instruction," attempts to find the nearest previous instruction that seems reasonable. What it actually does is this: first it jumps back in memory twelve bytes, then it disassembles its way forward to the last instruction that does not overlap the one you started in. The odds are very good that, during this process, the disassembler will find the proper alignment. This feature is, perhaps, the most interesting advance this disassembler exhibits. The other features that make it very convenient to use are explained in the operating instructions.

The disassembler was written by Douglas Wyatt, with a little bit of the code (and probably most of the bugs) supplied by me. A few comments on changing Poly BASIC to your BASIC might help. The exclamation point (!) means "PRINT." Anything shown in lowercase may be changed to uppercase. We think that it is nicer for the computer to talk in standard English if it can, so we use lowercase where appropriate. The function INP(1) grabs a character from the keyboard. Thus, lines 110 and 120 take a character, C, and ask if it is a RETURN (ASCII-13). If it is, the computer does a RETURN and a LINE FEED. The slash (/) allows two instructions to appear on the same line. You can modify this so that they are on separate lines if your BASIC doesn't support this feature.

Knowing the symbol equivalent of various ASCII codes is useful in understanding the program. Your BASIC must have the PEEK function, of course. On some, this is called EXAM. We also use TAB. If you don't have the multiway branch (the ON instruction) you will have to use a list of IFs. It's not all that hard.

Operating Instructions

When the program is running, a press on the space bar disassembles the next instruction. Any key

Program listing.

other than a command just repeats the previous instruction. The following six commands form the entire assembler. When they are pressed, no RETURN is required if you use the INP function or its equivalent.

A(ddress)

When this command is given, you have to supply a hex address. Disassembly proceeds from that address.

J(ump)

If the instruction just disassembled was any kind of jump, this command causes disassembly to proceed at the jump's destination address. Thus, you can use the disassembler to trace through a program.

B(ack)

This causes disassembly of the previous instruction.

C(all)

If the instruction just disassembled was a CALL, then this instruction causes the first line of the called subroutine to be disassembled. Disassembly proceeds through the subroutine until you give the instruction.

R(eturn)

Disassembly proceeds with the statement following the CALL. Subroutines may be nested. Use of the R(eturn) instruction is not limited to when you find the subroutine's RTN instruction; it can be used at any time to return to disassembling the calling program.

P(revious instruction)

This command has the disassembler go back twelve bytes, then scan forward to the last instruction before the one you started in, trying to align itself to the correct instruction boundaries. If the code you are disassembling isn't making sense, try this instruction. There is a good chance (although it is not certain) the disassembler will now be properly aligned with the program. Of course, if you are in a region of memory that is full of data, then a glance at the ASCII or the hexadecimal columns should show the structure of the data.

Output Format

The address appears at the left edge, followed by the contents of the location (and the next one or two locations if the disassembler thinks that a multi-byte instruction lives there) in hexadecimal. Next is the ASCII representation of those contents (or underlines if they are not printing characters). This is followed by the assembler mnemonic, and then an asterisk.■

Antenna Bonanza for 10

—CB is good for something

Modifying your antenna is easy.

Joe Goode W6LVT
918 North Mabury St.
Santa Ana CA 92701

Most CB equipment can be modified, tuned, or used as is to operate on 10 meters. Many excellent articles have been published on the modification of transceivers. I am working on a vfo to work with these modified units. Each CB modification results in the necessity of a good 10 meter antenna.

The CB industry is manufacturing an array of excellent economical antennas that can be easily modified to 10 meters with a near perfect match. If you are looking for a real bargain, don't overlook your local swap meets.

Here is how to modify several types of antennas. The tuning will be covered later. The actual length will vary with each type of antenna.

Mobile—Base-Loaded Steel Whip, 47 Inches

It was necessary to reduce the whip length to 41 inches. The original whip was retained for 11 meters and another whip was cut for 10 meter operation: swr, 1.2 to 1—29 MHz.

Fixed Station—Vertical Half Wave

No modification: swr, 1.8 to 1—29 MHz. This antenna is known as a Starduster. If you don't mind a little swr, use it as is. Cutting it to length would be difficult since the coax is inside the bottom element.

Fixed Station—Quarter-wave Ground Plane

This antenna had three 106-inch radials and one 106-inch vertical driven element. The vertical element was shortened from 106 to 96 inches. The three radials were not modified: swr 1.2 to 1—29MHz.

The above antennas are being used on 10 meters. The measurements are actual. The following is theoretical.

Mobile—Quarter-wave Whip

Reduce length in accordance with the pruning procedure.

Mobile—Fiberglass Wire-wound

These antennas are made by winding wire around a fiberglass rod and then applying shrink tubing over the entire length. The tuning consists of removing turns of wire from the top end. The frequency is determined by the number of turns rather than the overall length of the glass rod. The size of wire determines the power handling capability. 18-gauge wire will handle 200 Watts.

Fixed Station—5/8-wave Vertical

These antennas normally have a loading coil to obtain electrical length without extending the mechanical length. Tuning would consist of reducing the mechanical length. The loading coil is located in the bottom end of the antenna assembly, and is not readily available for modification. If the loading coil is wound with small wire, it will not handle power. This is a good antenna to stay away from!

CB Beam Antennas

For the modification of beams, refer to antenna handbooks. Check swr and, if it is not more than 2 to 1 and it has a front-to-back ratio on receive, try using it as is.

A contact was made with a ham in Michigan who was using a vertical three-element CB Super Scanner beam as is. S9 reports were received on both ends of the contact.

Mobile—Center-Loading Coil

Tuning is accomplished by shortening the whip on the top end of the coil. The actual length will be critical and the bandwidth narrow.

Loading Coils

Antenna loading coils are sealed against moisture. This is normally accomplished by injection molding or potting the coil in epoxy. Do not attempt to remove coil turns unless you have determined a satisfactory method of resealing.

Power Handling Capability

Antennas without

loading coils are usually good for a kW. RG-58 coax is satisfactory up to 200 Watts input. Above this level, use RG-8/U.

Antennas with loading coils have power limitations. The larger the wire in the loading coil, the more power it will handle. Visual inspection of wire size is usually impossible due to moisture seals.

A clue to power capabilities is the outside diameter of the loading coil housing. If it's ½ inch or less, the power handling capability will be low, not more than 25 Watts. Excess power will cause the coil to heat and possible coil destruction. If there is a gradual increase in swr when the transmitter is turned on, the chances are that the loading coil is working up a fever.

Antenna Tuners

Antenna tuners are not required. Do not have one in the line when changing the length of the driven element. There is nothing wrong with trying a tuner with a CB antenna as is.

Pruning Procedure

Regardless of antenna type, the tuning from 27 MHz to 29 MHz requires the reduction of the electrical length of the driven element.

An swr bridge is required. The function switch is first placed in the forward position and adjusted for set level. The switch is then placed in the reflected position and the swr recorded.

Let's assume your modified transceiver has the following transmit frequencies: channel 1—28,965 kHz, channel 13—29,115 kHz, and channel 23—29,255 kHz. The center frequency is 29,115 kHz, so this is where you should adjust for minimum swr.

Minimum swr will not necessarily be a perfect match—1 to 1. It could be 1.3 to 1 or even 1.5 to 1. Do not settle for more than 1.5 to 1. This would indicate there is a problem somewhere.

A base-loaded mobile CB antenna, when operated on 10 meters, will show an swr reading of approximately 4 to 1. A quarter-wave base antenna will show an swr reading of approximately 2.5 to 1. A loading coil narrows antenna bandwidth.

While pruning a mobile antenna whip, cut off 1 inch at a time until the swr drops below 2 to 1. From this point on, cut only ½ inch at a time. The best way to cut a stainless steel whip is to use the edge of a file to notch the whip and then break off the notched piece with pliers. All mobile antennas have an adjustment screw which allows at least a ½-inch adjustment. With this adjustment, it is possible to obtain minimum swr at the center of your operating frequencies.

Pruning Fixed Station Antennas

The procedure is the same but not as critical. Cut off 2 inches at a time until the swr drops below 2 to 1, and then cut only 1 inch at a time until you obtain minimum swr at the center of your operating frequencies.

In the pruning of any antenna, all swr measurements must be made with the antenna in its permanent position. If it's going to be mounted on the roof, that's where you adjust it. If it's a mobile installation on the trunk lid, close the lid and position the car in the clear, away from all obstructions such as trees, buildings, and other automobiles. Close the car doors during swr measurements. ■

Lightning!

—a case history

If you're not careful, it's one strike and you're out.

Jerrold A. Swank W8HXR
657 Willabar Drive
Washington Courthouse
Ohio 43160

This is the story of what happened to Bernie Witherspoon W8GKM during the storm of July 14, 1978. It will show you what can happen even without a direct lightning strike to your antenna. Very few amateurs realize that a distant strike on a power line can cause more damage than a direct strike on your antenna. This is Bernie's story:

"At 4:30 am on July 14th, there was a sudden double click, together with a flash of lightning, in the radio room which is just off the kitchen where I was standing.

"I went into the radio room to check and saw that the pilot light on the two meter rig was out. It is left on all of the time so that the memory will hold the channels on which it is set.

"When I saw that the light was out, I knew that something was amiss. The antenna was switched off for storm protection, and it was free. Otherwise, the damage to the equipment (about $5000 worth), if connected to the antenna, would have been extensive.

"The lightning surge apparently came through the entrance panel and knocked out the fuse for the radio room. It then went through the NCR 12-volt regulated power supply, which originally sold for about $200, and now runs between $50 and $60 as NCR surplus. The inside of the power supply showed extensive damage. It was completely useless.

"The surge then travelled through the equipment via a common ground. It knocked out several transistors and a diode in the Yaesu FT-227R, knocked out a keying circuit in the TR-4CW, and burn-damaged the low voltage circuit in the L4B amplifier.

"It knocked out the power circuits in the R4C receiver. It went through the control box of the Ham III rotator and through one of the screws holding a rubber foot on the control box. The box was sitting on top of a transmatch. It jumped about one-half inch to the case of the transmatch and made a punched hole the size of a ten-penny nail. The surge burned a spot on the transmatch about the size of a silver dollar. It went through the transmatch to the outside, doing a little damage to the inside of the transmatch by burning some of the wiring.

"The amazing thing about this whole bit is that it went through the L4B low voltage panel and R4C control box, and then jumped to the chassis through the transformers without damage to the transformers. It went through several other transformers and did not damage them, although it did knock out two other transformers.

"The ground braid on the coax was welded to the Cantenna dummy load. Although the switch was off on the L4B, the filaments on the 3-500Zs were lit, but not at full brilliance. There were carbon deposits on the switch contacts making a high resistance connection.

"The fuse on the wiring for the rest of the house was not blown. However, it did burn out the transformer on the furnace and the doorbell transformer, plus various small items around the house.

"Since there were two cracks of thunder, I went out to see if the antenna showed any damage. I found half of an insulator on the ground. A neighbor who had been watching said that it looked as if little fireballs were dancing all over the antenna.

"I found that one of the insulating blocks, which hold the center conductor, was broken in two and showed burns. On the metal inserts, which hold the insulators, one of the screws was burned and badly melted. Also, there was some melting where the insulator block was burned in two.

"That strike went down the coaxial line, and each one of the wires in the RG-8 showed signs of being burned. It was not charred, but discolored. When I took the jacket off some of the coax and looked at the clear insulation, it looked like a dark streak inside. Stripping that off, I found that on the inside of the cable each stranded wire was burned.

"Where the coax entered the house under the porch there was a 15-foot length of RG-8, and in that, a PL-259 and a PL-258 were fused together. I was finally able to pry them apart. It short circuited three other PL-259s, badly burned a PL-258, and melted metal on the outside so that it was not usable. There were short circuits in three places in the 15-foot length of RG-8 under the house.

"The estimate of total damage was most fortunate—$332.67. However, I did much of the repair work myself. I replaced the bell transformer and the cable to the dum-

my load.

"The coax switch to the antenna was burned but usable.

"The transmatch was homemade, and a replacement cabinet and panel would cost from $55 to $60. I listed it as $15. I fixed the rotator and L4B myself, and sent the R4B to Drake.

"I also fixed the TR-4CW myself and the VTVM. If all that had been sent out, the cost would have been much more.

"I sent the Yaesu FT-227R to Columbus to be fixed, and they had to send for parts. It took me one month to get it back.

"Except for the Yaesu, I was on the air in a few hours. I have had this setup, and it has always been connected through storms, since 1959, and nothing ever happened, but after 28 years it finally did. I guess if you wait long enough, something will happen.

"Some years ago my father was in the yard holding a steel rim off a buggy, and a cat. Lightning struck the steel rim and went through him, struck the cat, and then hit a boy standing nearby. It killed the cat and the boy, but did not kill my father.

"I have seen lightning strike the ground in an open field less than forty feet from a tree which was thirty or forty feet tall, so it isn't always the highest point that gets hit.

"I have seen it strike water. Once, when I was in the army, I saw it hit a telephone pole. The top third of the pole disintegrated.

"A man on a farm was once hit by lightning and killed. The nails in his shoes were formed into little balls which were rammed up into his feet all the way to his ankles."

Some years ago, W8MPJ, a friend of mine in Dayton, Ohio, had his antenna hit by lightning and it went through the wiring in the house. It burned a pattern on the wall all the way through the house, wherever there was wiring. Strangest of all, in the bathroom, it stripped all the mercury coating off the mirror. On the little side lights by that mirror, there were little knurled nuts that held the lights to the brackets. Those little nuts were unscrewed by the strike and were found on the floor.

The light fixtures were hanging by the wires, still connected. The total damage to the house, for replacing the wiring and fixtures, was over $2000.

Some years ago I had an NCL-2000 amplifier, which was on, and at the same time I was seeing in the distance what we usually call heat lightning. It was a clear day, and there were no clouds in the local sky. But in the distance, miles away, these little flashes could be seen, but no thunder was heard. I noticed that every time I saw these little distant flashes, my NCL-2000 tank would flash over. I disconnected it and stayed off the air until the storm passed.

There is only one word for lightning—unpredictable.

I now have across my 220 line in the radio room a General Electric, 2-pole valve-type secondary lightning arrestor. It should be connected at the input box to the house. It would then protect every appliance in the house. I have it connected across the line to my radio room for the protection of my equipment, since putting it across the input fuse panel would require extensive wiring. GE says that it would completely protect one against these lightning surges. ■

Build a CW Memory

—fun!

Try another one of our $10 projects.

Larry Kasevich WA1ZFW
78 Jackson Road
Enfield CT 06082

Probably the most useful of electronic components today is the solid-state memory. This device comes in all sizes, packages, and families. There are RAMs, ROMs, PROMs, EROMs, static and dynamic, and even something called "bubble" memory. These devices are used in so many applications that the list is endless. Even with the latest and greatest microprocessors, the memory is as important as the microprocessor itself.

With the availability and low cost of solid-state memory, I put it to use for the amateur radio operator. Since CW only consists of two states, carrier on or off, this type of memory suits this application quite well. My goal was to design a unit that would be a useful tool for the CW operator. It consists of a

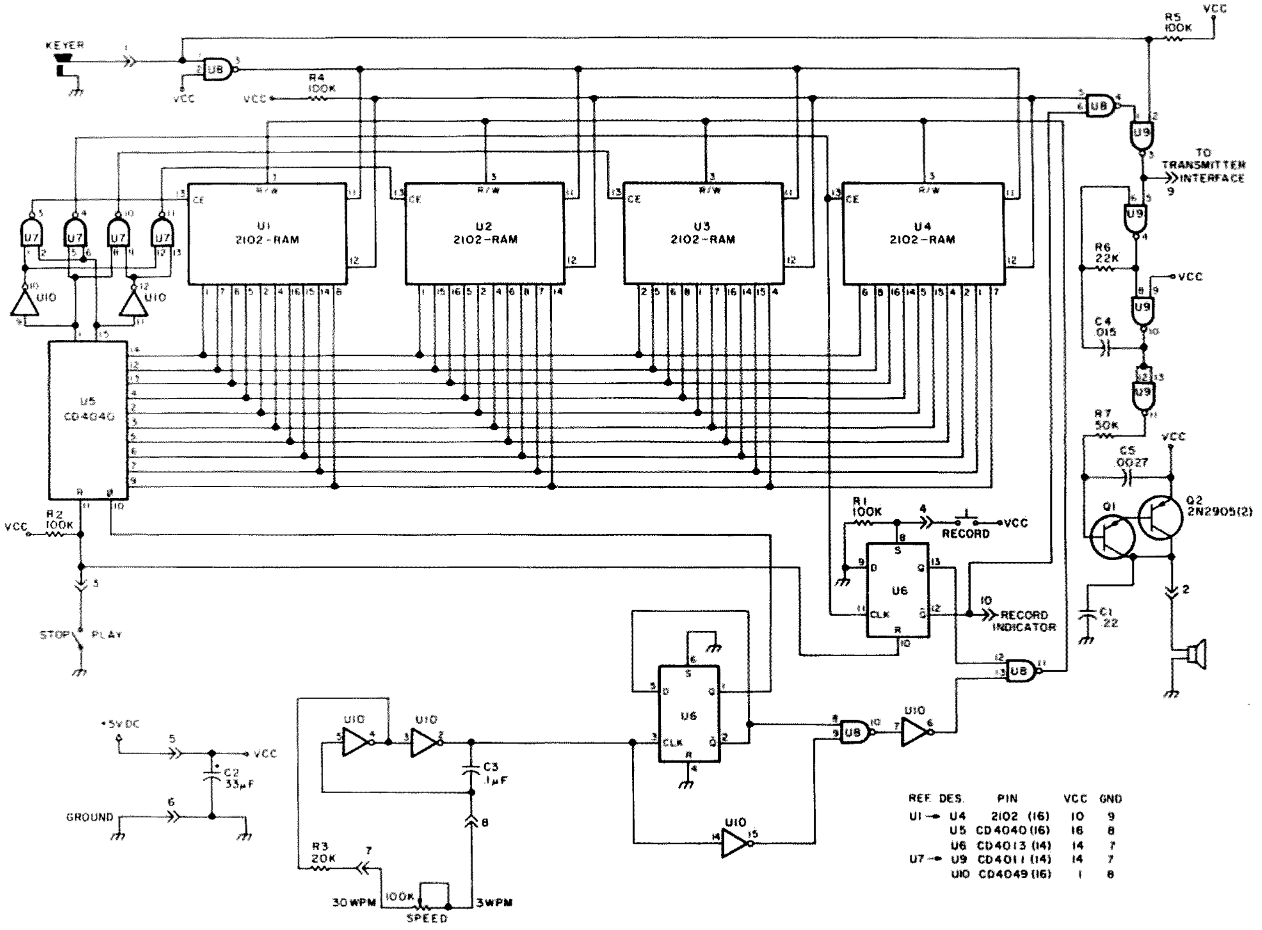

Fig. 1. Code Memory schematic diagram.

memory to store a coded message. The unit actually records what an operator sends with his key. In order to make this recorder more versatile, the rate of speed of the code can be varied without changing the output tone. This makes the unit useful for the beginner when learning the code because he could increase the speed slowly. (This unit could also be valuable in contests for repetitive information such as name, QTH, etc.—ed.)

The schematic and parts identification are shown in Fig. 1. There are ten connections to the circuit. The keyer is connected between pin 1 and ground. This could be a straight key or an electronic keyer as long as the signal is open or ground. An 8-Ohm speaker is connected between pin 2 and ground. The speaker will produce a tone whenever the key is depressed or whenever code is being played back from memory. This tone can be adjusted using either C4 or R6. A volume control can be added by simply putting a pot in series with the speaker. Two switches control the operation of the unit. The play/stop switch, connected to pin 3, when in the open position, applies a reset to U5, the memory address register. This puts the unit in a mode where the memory is idle and the unit can be used as a code-practice oscillator. With ground applied to pin 3, the unit will play back the code that is in the memory. The other switch, the record button, is connected to pin 4 and, upon momentary depression, sets the U6 flip-flop and puts memory ICs U1 through U4 in the record or memory-write mode. The play/stop switch must be in the play position during recording.

Power is applied to pins 5 and 6. A positive 5 V dc is required at about 500 mA. A normal transformer, rectifier, and filter with a voltage regulator, like an LM309, works just fine. To control the speed, a 100k pot is connected between pins 7 and 8. This controls the clock which is used to advance the address of the memory. This pot can be set in any position to record, and any position for playback. With the 4096 bits of memory, good resolution can be obtained from 3 wpm to 30 wpm. Don't try to record 30 wpm code with the pot set for 3 wpm. It won't work. Message times will vary from about 1 minute for a speed setting of 30 wpm to about 6 minutes for a speed setting of 3 wpm.

The Code Memory can drive a transmitter, if desired, provided an interface circuit is used. Pin 9 is available for this, but, note that the signal is CMOS, which is extremely limited in its drive capability. Consult the data sheet for the CD4011 NAND gate before you design an interface. Pin 10 can drive a buffer which, in turn, can be used to drive an indicator to tell the operator that the unit is in the record mode. It should be noted that when in the record mode, the unit will stop recording once the memory is full. The operator can instantly start from the beginning at any time by cycling the play/stop switch.

This Code Memory should be a useful tool for any CW operator, contester, or person learning the code. The cost of the components is less than $10.00, so not only is this a practical project, but also an inexpensive one. To make the construction easier, a two-sided printed circuit board is available for $10.25 from Larry Kasevich WA1ZFW, 78 Jackson Road, Enfield CT 06082. ■

Wire-Wrap on a Budget

—home-brew your tools

For building many integrated circuit projects, a printed circuit board is considered essential. The alternative is to make many connections in very limited space, and point-to-point soldering techniques are most tedious. One alternative to these wire techniques is wire-wrapping, where each connection is made by wrapping a square post with no. 28 to 30 wire—no solder is required. One limitation to starting wire-wrap construction is the cost of the tool—$6.00 (minimum)—and many people are reluctant to get the starting tools. If your budget is limited and you want to experiment with wire-wrap, here is a no-cost way to begin.

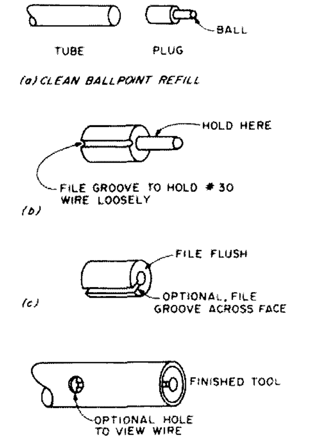

Fig. 1. Wire-wrap tool construction.

Almost all of us have a few dozen ballpoint pens that refuse to write. Inside many, the refill is a metal tube. These are the type you need; get at least two of them. Some of the more expensive refills have larger upper reservoirs which also make good handles, but any metal ones will suffice. First, clean the remaining ink out of each one. The metal plug containing the ball point should be carefully removed to clean it. Be sure to save the end piece! Cleaning is the hard part and is a little messy. Soapy water and a few pipe cleaners help.

Next, look at Fig. 1 and see how to file the notch in the side of the plug. This is the groove in which the wire will be placed, so make the V-shaped groove large enough for a #30 wire or a little larger so the insulation can also slide in if you prefer the first turn to be of insulated wire. Do not cut the pen end off before you file the groove. It is easier to hold it by that end while you file, and it's small enough anyway. (I lost the first one somewhere in my shop.)

After you have finished the groove, carefully cut off the small end of the plug flush with the large diameter. You may insert this almost all the way into the refill tube now and check to see if a wire will pass through the groove satisfactorily. The center hole should be just the right size to fit over a standard .025 x .025 pin. You may wish to file a groove across the diameter end of the plug, connecting the groove and center hole. This aids in causing the very end of the wire to be wrapped against the pin, but is not essential.

Another optional feature is a small hole, just above the groove in the plug, in the wall of the refill tube. This allows you to see the wire pass through the groove. If you look into the hole and cannot see the wire, it went into the center hole, which is wrong. Again, this is an option—drill as small a hole as possible. A no. 80 is large enough, but few of us have that small a drill. A hand grinder with a no. ½ dental burr will cut a nice groove and also drill a small hole, if you have access to one.

This completes the wire-wrap tool. Try it out. With a little practice, you can do as well with it as with any professional model. You will find that more time is spent cutting and stripping wire (if you do not buy the prestripped lengths) and inserting the wire than is spent in wrapping, so that manual tools are only a slight bit slower than motor-driven ones.

Now for the eraser for your mistakes! You need an unwrap tool, too, because you will want to remove wires to make tests, make changes, and correct errors. Since you may wrap a wire in either a clockwise or a counterclockwise direction, you want a tool that works in both directions. Look at Fig. 2. This time, the plug is put into the tube, the small end cut off and filed flush, and the plug is filed back to form a sharp edge which will pick up the end of the wire and unwind it. A triangular file or jeweler's file will help here to get the undercut edge. The edge should be beveled somewhat, as shown in Fig. 2(c). Grooving below the outside edge of the tool is optional. This makes it pick up the wire a little more easily sometimes. Try it on a few of your wraps to see how it works.

Now you are all set to wire-wrap your next IC project. All you need is wire, sockets, and a stripper. A cheap stripper which works well on no. 30 Kynar insulated wire-wrap wire is hard to find. Try using a good double-V stripper set carefully to not nick the wire. ■

12 Volts, 5 Amps, 3 Terminals

—what could be simpler?

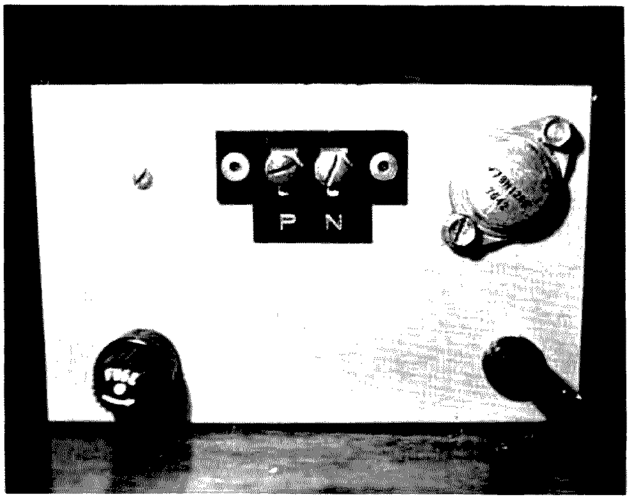
Protect yourself from shorts and headaches.

Gary Toncre WA4FYZ
13764 S.W. 54th Lane
Miami FL 33175

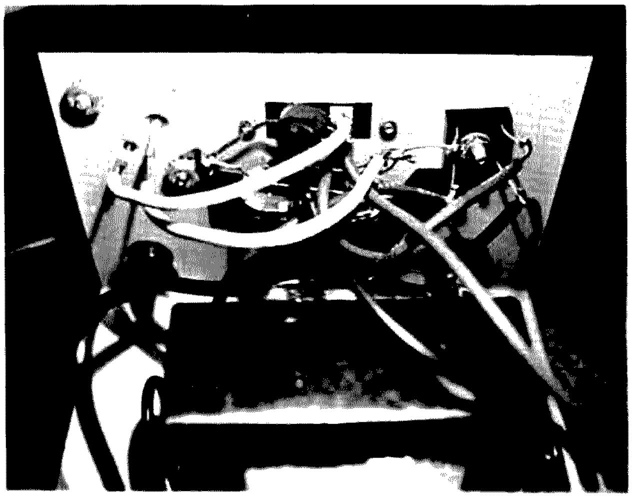
It seems that in the last several months, *73* has carried more than its share of regulated power supply articles. I started to build one of them for use with my TR-22 and my Heathkit® amplifier. Sure, for three bucks or so, anyone can build a regulator for his power supply using a 2N3055 pass transistor, a zener diode, and a few resistors. The only problem is that such a circuit has no protection against short circuits and excessive current draw. To add the extra circuitry for protection can increase the cost considerably.

The solution to my problem was found in a new regulator subsystem by Fairchild. The device, a Fairchild 78H12, is a complete regulator with internal current limiting and thermal-shutdown circuitry in a TO-3-type case. It will handle 5 Amps at 12 V dc before current limiting begins. In other words, the device is indestructible. The price is about $9.00, which is expensive in this day and age, but not for complete protection in a TO-3 case. Other than the power supply capacitors and an output bypass capacitor, no other external parts are needed.

Fig. 1 shows a schematic of my supply. I added the regulator to an already-assembled power supply. Because the device is complete in itself, modification of the power supply was minimal. Also, the company that built the power supply was thoughtful enough to have drilled the holes for a TO-3 pass transistor. So, I simply mounted the regulator in the holes provided, and used a little heat-sink compound. If you plan to draw more than a few Amps, I would recommend using a heat sink—the bigger, the better. Two more steps completed the addition of the regulator. First, I had to break the positive lead between the filter capacitor and the output terminal strip. I then ran a wire from the capacitor to the input (pin 1) of the regulator, and a wire from the output (pin 2) of the regulator to the



The rear of the power supply shown with the 78H12 regulator installed in the holes that were provided by the manufacturer for a pass transistor. The white area around the regulator is not an insulator (the regulator case should be grounded to the chassis), it is common heat-sink compound which helps transfer the heat to the chassis from the regulator.



Inside view of the power supply. The two white wires connect the positive side of capacitors C1 to the input (pin 1) of the regulator, and the other is the output to the terminal strip on the rear. The capacitor on the terminal strip is C2, which bypasses any noise at the output of the regulator to ground.

terminal strip. It was also necessary to ground the negative lead to the chassis, since the case of the regulator must be at ground potential. Don't insulate the regulator from the chassis.

If you are building a supply from scratch, I would recommend the use of a 15- or 18-volt transformer. My power supply uses a 12-volt transformer which develops about 18 volts of unregulated dc output. But, after the current passes through the regulator, the output is only a regulated 11.5 volts dc. Although I haven't tried, I don't think that the full 5-Amp capacity could be reached. Keep in mind, though, that the peak input voltage to the regulator cannot exceed 25 volts.

I've used the regulator with my 2 meter amp and my TR-22. Under key-down conditions, the regulator will become warm to the touch after about one minute. Again, a larger size heat sink would allow more current to be drawn while keeping the regulator cool.

Two other versions are available: the 78H05 for 5 V dc, and the 78H15 for 15 V dc. Both will handle 5 Amps, and are priced the same as the 78H12.■

An off-the-wall program for on-the-air fun.

Cebrun Mayse
1916 Crosby Park Blvd. N.W.
Lawton OK 74505

Recently, I became a proud owner of a PC-100A printer. Now I'm swamped with printing tape, with every program imaginable all over the kitchen bar. There's even a program strip for how to figure wall paneling with prices and even how many panels per wall. It's amazing how a fellow can come up with off-the-wall programs, especially with the PC-100A.

00	54	20	03	40	84	60	34
01	03	21	06	41	02	61	01

19	54	39	41	59	04		

Fig. 1.

There was one problem that had been bugging me ever since I heard QSOs on ten meters about a year ago. The problem was how to use the orbit times supplied in *73 Magazine*. I've used the standard 115 minutes added to each orbit, but, when it comes down to the next initial orbit data given, it doesn't figure precisely. Once I got my new toy, it only took 40 feet of paper and an hour to figure out the math of it. The calculator I use is the Texas Instruments SR-56.

Now, here's how I figure orbits. After loading the program (Fig. 1) in the calculator, the next step is to load the initial time inversely into the calculator. For example, 0056:56 goes in as 56(sec.)R/S, 56(min.)R/S, 0(hrs.)R/S. At this point, the

00	33	19	03

11	01	30	94
12	17	31	35
13	29	32	02
14	64	33	34
15	06	34	02
16	00	35	97
17	94	36	41
18	33	37	42

Fig. 2.

program is awaiting the next day's initial time crossing, 0134:24, and this will be loaded as the previous time was, inversely: 24(sec.)R/S, 34(min.)R/S, 1(hour)R/S. The printout will be in decimal hours, such as 1.573333333. To change the decimal hours into hour-min.-decimal-sec., refer to Fig. 2. Use this program or subtract the hour and multiply the fraction by 60, which will give the minutes. Then subtract the minutes (the integers to the left of the decimal) and multiply the fraction by 60. This will produce the seconds. Fig. 3 shows the process via the PC-100A for 1 hour, 34 minutes, 24 seconds. Should your times start to run over the 23rd hour, remember to subtract 24 from the hours portion to be in the right frame. This is noticeable whenever you're figuring out orbit times in your locale. In reality,

```
1.573333333    -
         1.    =
0.573333333
0.573333333    ×

Tricky QSK

—a treat for CW

Dick Blasco
991 42nd Street
Sarasota FL 33580

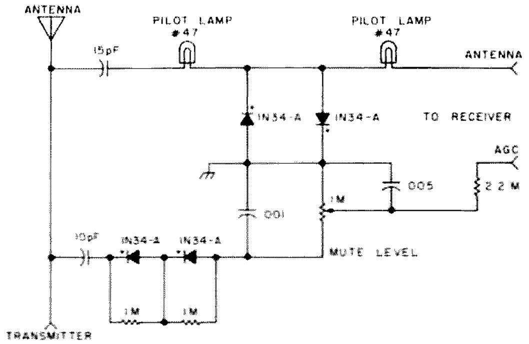

Fig. 1. Poor man's T-R switch schematic diagram.

Here's a dandy little evening project that will delight any CW-man's heart. This circuit (Fig. 1) is a refinement of a design which is simple and effective. The pilot lamps have a characteristic low resistance when not lit and a relatively high resistance as more current is passed through them. A high-level signal (from the transmitter) will exceed the contact potential of the 1N34A diodes and cause them to conduct, drawing current through the bulb. The bulb glows and acts to isolate the receiver from the antenna line. The circuit shown includes an additional lamp in the receiver lead for additional protection of the antenna coils.

Some of the rf energy is also sampled and rectified to provide a muting voltage. Simply connect this output to the agc line of any modern receiver and adjust the mute level for the desired signal level. This circuit works with the agc only when it's fully active, of course.

The circuit shown will work well at powers up to 100 Watts. Additional power may be handled by inserting additional pilot lamps in series with the 15 pF capacitor. This unit causes some loss of received signal strength, but its simplicity and effectiveness will far outweigh this in all receivers. If you aren't fully QSK by now, spend an evening and join in the fun! ■

Make Life Easier

—with a workbench speed control

Don Smith W4CQQ
5666 Flagstaff Rd.
Jacksonville FL 32207

Drilling holes in different metals often requires the use of a variable speed drill. If you don't own a multi-speed drill, the addition of this little circuit makes your hand drill a variable speed tool.

The bridge rectifier provides the full-wave pulsating direct current for the SCR switch and controls the angle of fire of the SCR. Diode D5 is used to counter the back voltage developed by the drill motor. Speed of the drill is varied by the 10k potentiometer.

Diodes D2-D4 should be rated at 200 volts piv and have a current rating of at least 12 Amps. The SCR should have a piv of about 300 volts and a current rating of 25 Amps. ■

Reader Service—see page 195

The Heath/Kenwood Connection

—RIT for the 104

Robert B. Lunsford, Jr. WB5QGI
1405 Stephen
Killeen TX 76541

How many times have I heard someone say, "I sure like Heathkits, but I don't know why they don't have RIT," or something similar? RIT, by the way, stands for receiver incremental tuning. (Sometimes it is called receiver-only tuning, or receiver offset, or simply offset.) This feature is found on many transceivers on the market today, and is a means of fine-tuning the receiver without affecting the frequency of the transmitter.

I am the proud owner of a Heathkit HW-104 and have in the past built and used SB-102s, HW-101s, and HW-7s and -8s. For the price, in my opinion, there is no better way to get on the air with state-of-the-art equipment. But no RIT!

Need for RIT

One of the main problems of not having RIT is what happens, for example, when I am talking with another ham who doesn't have RIT, and each of us is busy trying to improve reception of the other's voice. I will retune my transceiver to get a more "natural-sounding" voice; then he will retune his—and we both end up jumping around in frequency. This could end us up close to another station, causing some interference or being interfered with. Since the majority of hams on the air today appear to be using a transceiver, jumping around in frequency or being slightly off frequency are all too common events.

For a time, I used a Ten-Tec Argonaut for a bit of QRP work and became attached to using its offset feature. Upon completion of my HW-104, the first thing I considered doing was incorporating RIT and regaining some of the versatility of the Argonaut's offset control. After the "lids" were on the 104, however, and looking with some affection at my handiwork, I began to have second thoughts.

I've seen additions to equipment by others. Sometimes there is very professional work which doesn't detract from appearances, and in other cases you have to pretend you don't notice the additional switch, jack, meter, or whatever to keep from offending the obviously proud installer. (All the while you're fighting off an impulse to ask what brand of chewing gum was used to stick the little goodie on with.)

An Outboard Vfo

After weighing the pros and cons, I came to the conclusion that, if at all possible, RIT would have to be obtained without any modification to my new 104. Another factor is the ability of the 104 to go from one end of the band to the other without any peaking, tweaking, or anything save changing the vfo frequency (providing you did your antenna impedance design homework). Therefore, to be able to take full advantage of the broadband characteristics of the 104, it dawned on me that an outboard vfo would act as an RIT if proper switching or relay action were provided. In this case, not only would I get RIT, but I would be able also to make use of split operation—perfect for contests and DXing.

Once the decision was made to go to outboard or remote vfo, I began to look around for the best available remote vfo for the price, with ruggedness, durability, and stability, coupled with good eye-appeal. After using the 104, I knew the vfo in the rig was capable of meeting my ideals, but at the time, the engineers at Benton Harbor were on the verge of coming out with the SB-

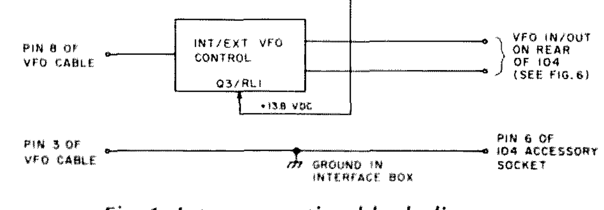

Fig. 1. Interconnection block diagram.

1	Vfo signal
2	Shield for vfo signal
3	Ground
4	12.6 V ac (for lamps) (13.8 V dc used in this project)
5	Relay signal input (goes positive on transmit)
6	Calibrator supply source, 9 V dc (not used)
7	No connection
8	9 V dc for internal vfo
9	9 V dc for external vfo

Table 1.

104A. The remote vfo for the 104 wasn't listed in the catalog, and it would not have had RIT had I obtained one.

Looking around and considering what was still available on the market, I discovered that I could get a remote vfo and RIT in the same box for about the same price as the Heath remote vfo, had it been available. The only problem would be with the controls necessary to obtain selection of internal or external vfo and the push-to-talk (PTT) control for selecting the desired vfo on transmit.

My selection was Kenwood's model VFO-520 remote vfo, since it was readily obtainable and promised to do everything I needed. According to the stated specifications, it was compatible with the requirements of the 104.

The plan from the beginning was to utilize an outboard vfo with no modification either to the vfo or to the 104. This was accomplished by placing all interfacing components inside a miniature aluminum box which I placed out of sight behind the 104. Interconnection between the 104 and outboard vfo was neatly tucked away, and the interfacing was done silently and effectively.

A small cable from the interfacing box connects to the remote vfo. Two short pieces of RG-58 or RG-174 extend from the interfacing box to the rear of the 104, where Heath has provided convenient jacks for the vfo output from the internal vfo and for vfo signal input. Normally, if no external vfo is used, a simple jumper is installed between the two jacks. Only three other wires are necessary: 13.8 V dc, ground, and the PTT signal line. Two-conductor mike cable, with shield, may be used for these last three wires.

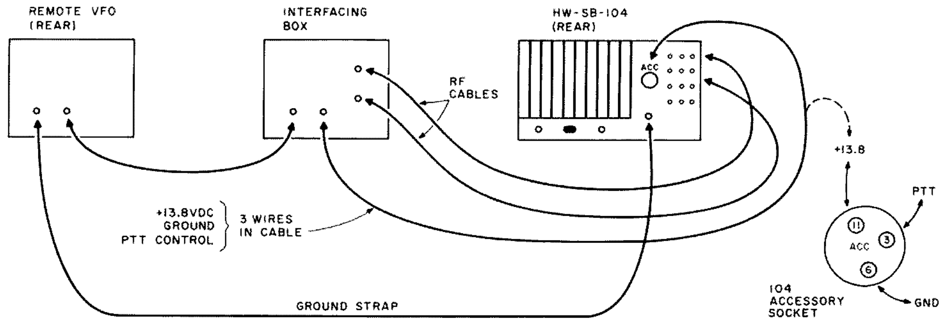

Fig. 2. Interfacing cable layout.

Kenwood has come out with a new design level since I purchased my VFO-520, but I imagine the new remote vfo and the old one are electrically equivalent. However, before buying the new one, in case the old one is hard to find, verification with a Kenwood dealer is recommended. Used equipment dealers should be eager to sell remote vfos if they have them in stock, because most hams don't need a remote vfo immediately when buying a new station, and this may leave the dealer with some extras.

The interfacing detailed in this article is what makes the combination work, so parts of the circuitry may be adaptable to other transceiver-to-remote hookups. Before planning to use combinations other than Kenwood to Heathkit, remember the two primary considerations: vfo frequency and which way the vfo is designed to tune. In this case, the Heathkit requires (a) that the vfo tunes from 5 to 5.5 MHz, and (b) that the vfo must tune backwards—which means that for a higher frequency of operation, the vfo will be producing a lower frequency, and vice versa.

The Circuit

A look at Table 1 will give an idea what the requirements of the vfo are and will aid in explaining what the interfacing connections accomplish. Block diagrams in Figs. 1 and 2 show how connections are made and demonstrate just how simple the project is. Figs. 3, 5, and 6 show the builder how few parts are required and may be followed as wiring diagrams. I will briefly discuss the various sections of the circuit, without details of the action of each electron, so that a better understanding of the circuit design and function can be achieved.

The power supply is the most complicated part of the interfacing box, but is actually a very basic circuit. For purposes of explanation, refer to Fig. 4 and notice that current flow is through zener diode D1 by way of resistor R1. Since a zener diode is designed to pass a large amount of current in the reverse direction when voltage across the diode reaches a certain level, it performs as a voltage reference device. In other words, as the voltage is raised across the diode, more current is passed by the diode at a certain voltage level, increasing the voltage drop across R1. In turn, this tends to stabilize the voltage across D1. The value of R1 is chosen to provide enough current for stable zener diode operation and to limit current through the diode to a safe value.

You may recognize transistor Q1 as operating in a standard emitter-follower amplifier circuit, but it is enough to remember that when Q1 is operating, a nearly constant voltage difference of a specific value is maintained between the base and emitter, mainly determined by the physical properties of the type of material used in making the transistor. For

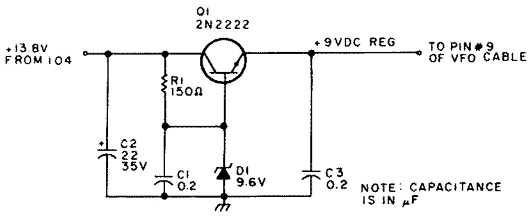

Fig. 3. 9 V dc regulated power supply.

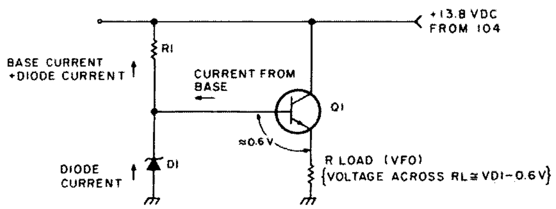

Fig. 4. Power supply simplified circuit.

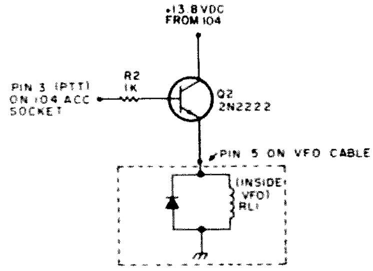

Fig. 5. Vfo relay switching circuit.

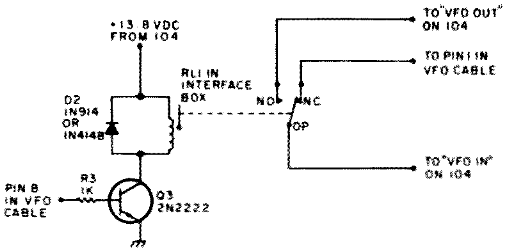

Fig. 6. Interface relay switching circuit.

silicon, which is used in the 2N2222, the voltage difference is about 0.6 V dc between base and emitter, and due to the clamping action of D1 on the base, the emitter circuit will supply current at a constant voltage. Capacitor C1 is used for insurance against the possible generation of white noise in the zener diode, due to random current paths in the silicon permitting "bumping," or friction, between groups of electrons, and resulting in a hissing sound.

Transistors Q2 and Q3 are used to operate relays, acting as current switches. R2 and R3 limit current in the base circuits to a safe value in the transistors and provide some isolation between the circuits. Diode D2 is used to limit to a safe value the "flyback" voltage generated as the relay winding is de-energized, since the inductive kickback voltage is usually high enough to jeopardize the switching transistor. Without this diode, the transistor could be "punctured" and destroyed.

Construction

All parts are common parts which either I had on hand or I bought at the local Radio Shack store. Table 2 gives a list of parts, and, while some substitution is possible, I recommend going with a winner and sticking with the circuit given, unless you like to experiment.

Silicone rubber compound, such as General Electric's RTV, would make mounting the relay a snap if you have it around. Perforated experimenter board can be used to mount the parts, but I soldered the parts to the pins on the 9-pin socket and rf connectors and experienced no mounting problems. Sockets for the rf cables between the interfacing box and transceiver may be considered unnecessary, but are recommended in order to keep everything grounded and shielded.

The VFO-520 comes with an interconnecting cable which has a 9-pin plug on each end. This cable is straight-through—that is, pin 1 goes to pin 1, etc., on each end of the cable. Also, pin numbering is standard, counting clockwise, starting from the large space between pins while looking at the bottom.

Remember to use the ground wire provided to strap the transceiver and vfo together, since depending on signal wire shields for grounding is poor practice. If the ground wire provided isn't long enough, one should be made up, since noise could be experienced later as connectors become dirty or oxidized.

Operation

Since placing the remote vfo in service, I have not had any problems whatsoever. Stability is as good as the 104 vfo, and that's pretty good. In fact, for almost all general operating, the Kenwood vfo is used exclusively. At first, one might think the price is pretty high just to get RIT, but not only do I now have RIT and the capability of comparing vfo operation, I also have the ability to set up operation on another band by verifying frequency availability and then moving with just a flick of the bandswitch. Actually, I now have the same capabilities as if I were using a separate receiver and transmitter, except for crossbanding.

I thought at one time I had a stability problem, but it turned out to be an oxidized bandswitch in the 104, and cleaning with a pencil eraser did the trick. (Take note, 104 owners.)

The function switch on the remote vfo gives total control over operating frequency. The four positions of the function switch are as follows, along with operating mode if the indicated position is selected:

OFF—Remote vfo is off. Transmit and receive frequencies are controlled by vfo in rig.

REC—Remote vfo controls receiver; rig's vfo controls transmitter.

REC/XMIT—Remote vfo has total control.

XMIT—Remote vfo controls transmitter; rig's vfo controls the receiver.

Summary

I don't expect any trouble from my vfo in the future because, upon inspection of the interior of the VFO-520 (I have a thing about looking inside every new thing I buy), I found good construction techniques were used, both electrical and mechanical. There was shielding where I didn't expect it, in fact. There is no reason why the VFO-520 cannot be used with other rigs with a little bit of homework, and I hope I've made it clear enough so others can duplicate the project without too much trouble. I also hope that those who do will get as much enjoyment out of the expanded operating capabilities as I have—all without modification to the rig or the vfo. ■

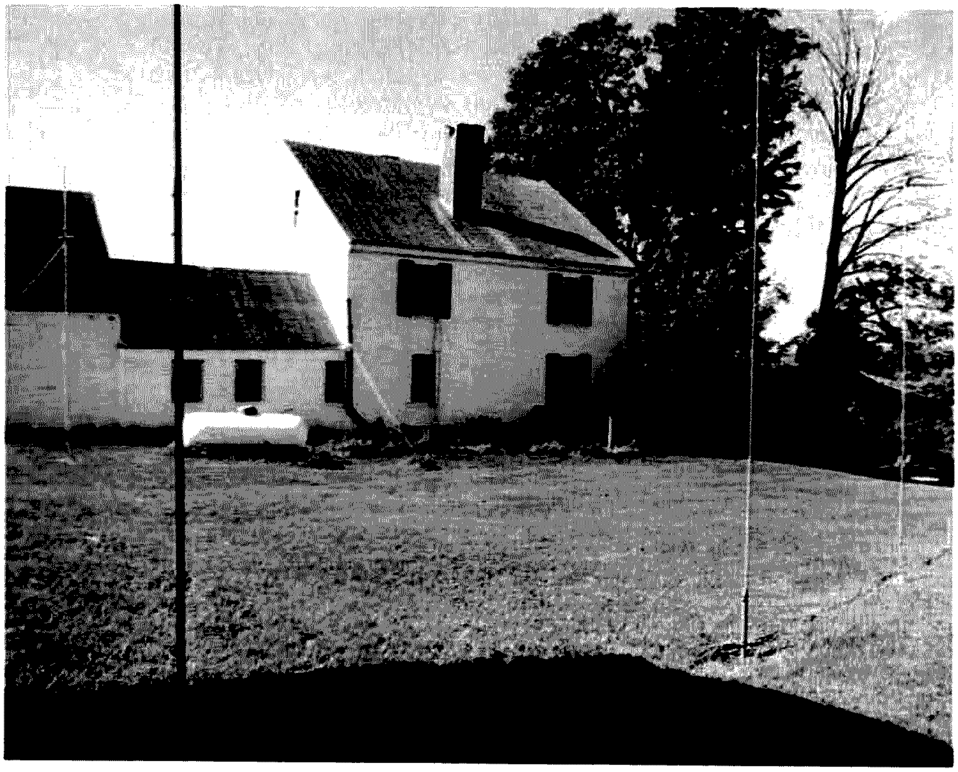
An 8-Element, All-Driven Vertical Beam

—super array for DX

Good news from New Hampshire.

The most popular 20 meter beam antenna in use today is the yagi mounted horizontally on top of a tall tower. A "package" price on such an antenna, a three-element triband beam, a rotator, a 51-foot crank-up tower, and 100 feet of coax and rotator cable was recently advertised in ham magazines at $1,095. In addition, you will have to pay for shipping and cost of erection (including concrete, guy wires, anchors, etc.), to say nothing of the legal fees to defend yourself against the local zoning board because you erected a 51-foot structure on your property without a building permit. To avoid the above expenses, I designed and built a vertical array over a ground plane with a maximum height of only 16.4 feet and a total erected cost of only $60, plus a few bucks for the extra RG-58/U needed, thus saving well over $1000.
well over $1000.



A general view of the array in relation to the shack which is in the upper rear room of the old farmhouse.

Vertical beams described in the literature are generally either two- or four-element ground-mounted phased arrays for 3.5 or 7 MHz.[1] The directivity of these beams can be changed by various switching arrangements. The usual method is to switch in coils of coax cable cut to the required length for the number of degrees lag required. This is relatively simple for two elements. However, the gain from such a two-element beam is also relatively low. To increase the gain, it is necessary to increase the number of elements in the beam. Four is usually the

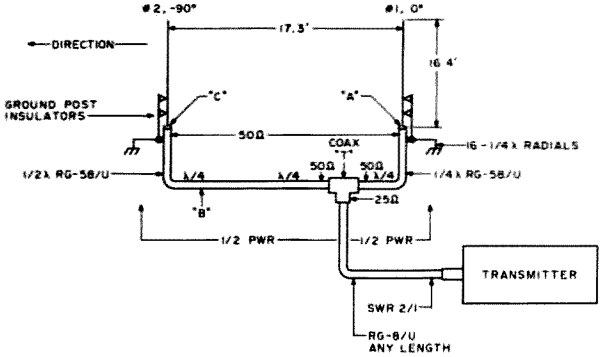


Fig. 1. Method of feed for the 2-element phased array.

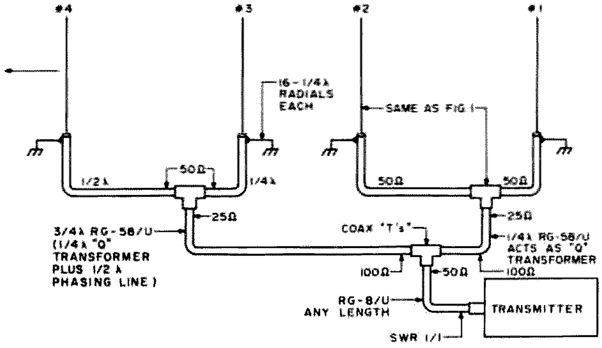

Fig. 2. Method of phasing and power division for the 4-element array.

maximum number of elements used. These may be arranged in a straight line, a square, or a triangle, with the fourth element in the center.[2] The complexity of the switching and phasing increases at a faster rate than the gain from such an array. Although the gain is low from such an array, it is more than adequate on 3.5 and 7 MHz, where rotatable beams are very expensive and difficult to construct.

To get enough gain on 14 MHz from such an array to be competitive with yagis and quads on towers, at least eight elements are necessary. Therefore, I sketched up an eight-element phased array with switchable directivity, but gave up the idea after calculating the number of relays and the feet of coax cable that would be needed.

Parasitic Array

One-half of an eight-element yagi (split down the middle) mounted vertically over a ground plane looked really interesting[3] since it only required a single length of RG-8/U for a feeder and could possibly be made into a tribander for 20/15/10. An eight-element parasitic beam could not have its directivity switched, but since I had already given up that idea, I decided to go ahead with a large high-gain unidirectional beam fixed on Oceania. It was decided to start with four elements, a reflector, a driven element, and two directors, later expanding it to eight or more elements by adding more directors. With this in mind, I reviewed the literature on yagi antennas. A 20 meter beam is generally limited to three elements only because of the difficulty in supporting a long boom 50 to 60 feet up in the air. Imagine the wind and ice load of an eight-element beam with an 80- to 100-foot boom! This is no problem on VHF where high-gain 10- to 16-element yagis are common. Neither is it a problem on HF when the beam is vertical with each element mounted on its own ground post.

Since I wanted my beam to point to Australia, which is 270 degrees true from central New Hampshire, I drove a 5-foot ground stake of 1-inch diameter pipe into the ground and attached the driven element to it. At precisely noon sun time, a stake was driven at the end of the shadow of the driven element.[4] This established true north. Next, I measured off 90 degrees and drove another stake, marking the true east/west axis of my new beam. The three ground posts for the reflector and two directors were installed next, together with their elements, along this east/west line. A length of RG-8/U was hurriedly run from the shack to the driven element just before dark. There was no time to install radials, but I did have a good (?) ground, four pipes driven into the moist soil to a depth of 3 feet.

At 6:00 am the next morning, I called CQ and was elated that VK3AKK ,answered and gave a report of strength 5 on a rather poor band. I was delighted that the first QSO on my new Australian beam was with a VK station. Anxious to see how much better it was than my other antennas, I switched in turn to a Hustler 4BTV, a dipole, and an eight-wavelength longwire. Ken came back saying: "Don't slash your wrists or cut your throat with this report, but although your new beam is a good S-5, the 4BTV ground plane is an S-7 and the dipole is an S-9. The longwire (pointing at South America) is an S-6."

So, back to the drawing board! It seems I have read somewhere that a pipe driven into the ground makes a good lightning arrester but not an rf ground! An swr check showed an extremely high swr ratio, so a 50-Ohm dummy load was placed at the far end of the coax. The swr came down to 1 to 1, showing the cable to be OK. Realizing that the trouble was probably due to the lack of a ground plane, four radials, each ¼ of a wavelength long, were installed at the base of each element. The swr immediately came down to 3 to 1.

A field-strength meter was set up about 60 feet in front of the beam, and the lengths of each element were varied in steps of 2 to 3 percent both ways with no very conclusive results. The elements did not want to tune. It appeared that I was trying to adjust the length of an element an inch or so at a time against some unknown random length of a ground system. Four more radials were added, making a total of eight radials per element. I reset the lengths of each element to 5 and 10 percent shorter for the directors and 5 percent longer for the reflector and ran another swr check. The swr was now down to 2 to 1, a worthwhile improvement.

The next morning, another CQ raised VK4AGL. The new beam was beginning to work. Joe gave me the following comparative report: new beam S-9, dipole S-8, 4BTV S-7, longwire S-5. It appeared I was now in business, so I started adding more elements, more radials, and a 4-to-1 step-down transformer. After each change, I would collect comparison reports for about a week. The greatest improvement in reports resulted from increasing the radials to 16 per element. The final 8-element

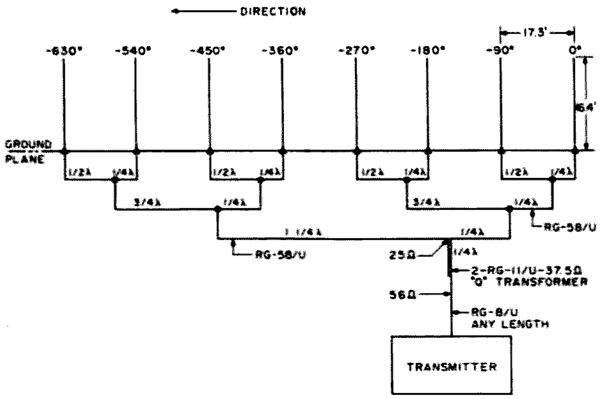

Fig. 3. Feeding and phasing an 8-element array. Note the 37.5-Ohm Q transformer. Refer to Fig. 5.

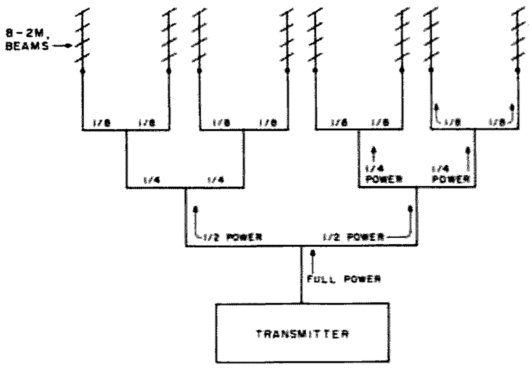

Fig. 4. Feeding eight 2 meter beams in phase with equal power. Feedlines to all beams are of equal length for in-phase operation. This is the type of phasing harness to use for broadside directivity of the 8-element array.

yagi beam gave a consistent two S-unit increase in signal strength (about 12 dB) over the best of my reference antennas. I still was not happy with the beam because I could not see any definite results from trying to tune it. Adjusting the lengths of each of the eight elements became very tedious and time-consuming. It was decided, therefore, to try an all-driven 8-element phased array, starting with two elements, then going to four, and then to all eight.

Phased Array

In a phased array, there are two things to watch out for: First, if ¼-wavelength spacing between elements is used for end fire, then there must be a 90-degree lag between elements, and second, the power must be divided equally among all elements.[5] The first problem is solved by feeding the first element directly from the coax from the transmitter and then feeding the second element through an extra ¼ wavelength of coax. Now, obviously, an electrical ¼ wave of coax, 11.4 feet, will not reach between two ¼-wave spaced elements, 17.3 feet; therefore, we must lengthen the coax to each element by an equal amount. For ease in grid-dipping each length of coax, I chose to lengthen each coax by ¼ of a wave. Refer to Fig. 1 for the power division and phasing of the first two elements. The formula for the electrical length of a quarter wavelength of coax is: L in feet = 246 × V/f = 11.39 feet when f (frequency in MHz) = 14.25 MHz and V (velocity factor) = .66.

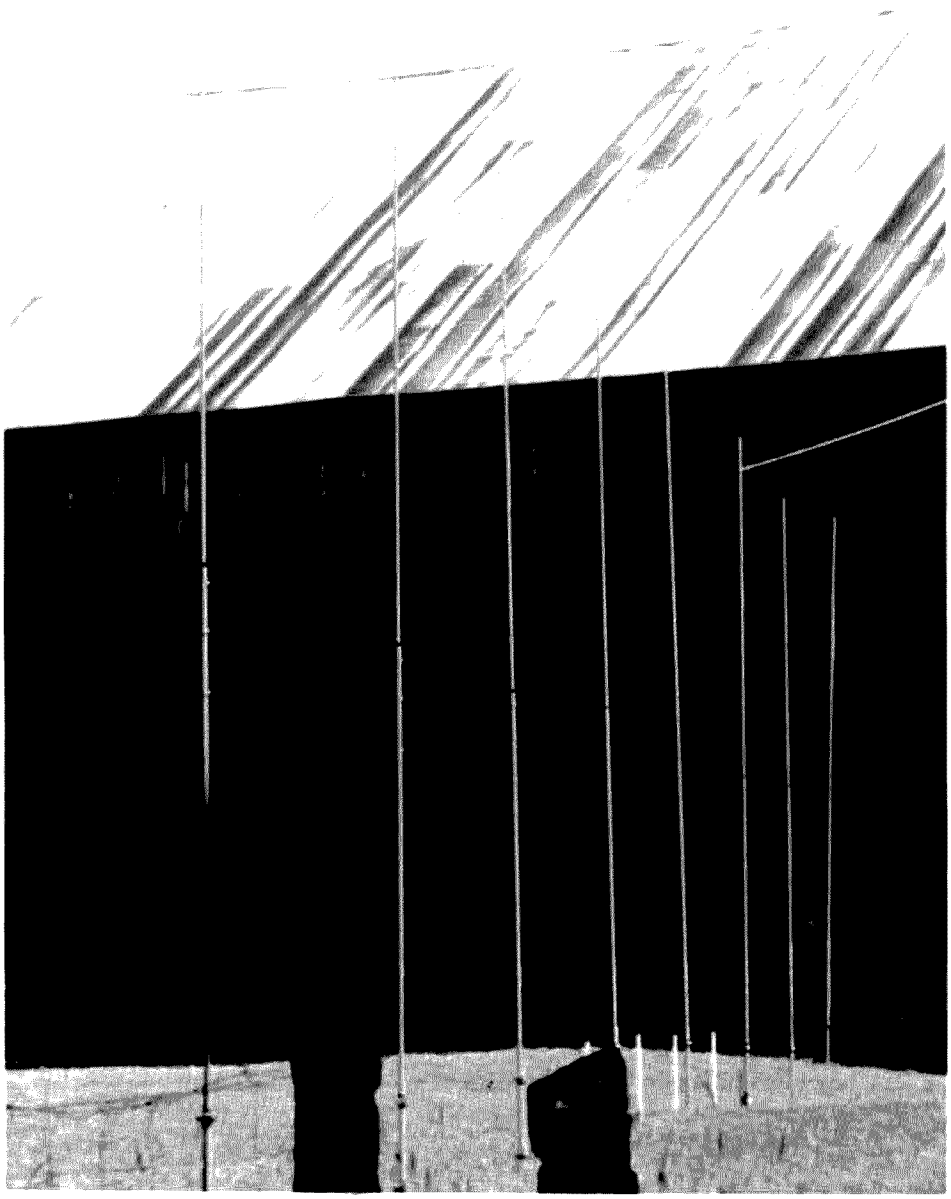
Handbooks say that V equals .8 for foam dielectric RG-8/U and .66 for solid dielectric. This makes a good starting point. Be sure to grid-dip your particular coax to 14.250 MHz, each time checking the grid-dip frequency on your receiver. Solder a 1-inch diameter loop onto a coax chassis fitting and then screw on the length of coax to be checked. If it is solid dielectric cable, then it should be cut to a few inches longer than .66 times ¼, ½, ¾, or 1¼ wavelengths and then pruned to length with the grid-dipper. When dipping the ½-wave coax, set the dipper at 7.125 MHz and read its second harmonic at 14.250 MHz. For all odd quarter wavelengths of coax, set the dipper at 14.250 MHz. The end of the cable you are pruning must be open-circuited. It was interesting to note that none of my coax had a velocity factor, V, of .66; it varied from .59 to .62.

Referring again to Fig. 1, you will note that the power from the transmitter is hopefully divided in half by the coax "T", one half going to element #1 and the other half going to element #2. Also note that points A and B are equidistant from the coax "T"; therefore, there is no phase difference between them. There is, however, an additional ¼ wavelength of coax between points B and C; therefore, it takes the signal that much longer to reach point C. Since there are 360 degrees in a wavelength, ¼ of a wave equals 90 degrees, and the signal in element #2 is said to "lag" that in element #1 by 90 degrees. This same method of feed will be used for each pair of elements.

This 2-element phased array was used for a week working VKs and ZLs, with results equal to the 4-element parasitic beam. Of course, by now I had a better ground plane than earlier. Next, two more driven elements with ¼-wave spacing were added. In each case, the division of power was hopefully accomplished by simply installing a coaxial "T" in the line as shown in Fig. 2. Phasing was accomplished by feeding the two pairs of elements through a ¼-wave and a ¾-wave section of coax as shown. The reason for doing this was to avail myself of a pair of ¼-wave matching transformers. If each of the driven elements had feedpoint resistances of 50 Ohms, they would be in parallel at the first "T", producing 25 Ohms of output. Now, if we connect in a 50-Ohm coaxial transformer an odd number of quarter waves in length, we can raise this 25 Ohms to 100 Ohms. $Zo = \sqrt{Zr \times Zs}$, where Zo is the line impedance (in our case, for RG-8/U, 50 Ohms), Zr is the impedance at one end, and Zs is the impedance at the other end, 25 Ohms. $Zr = Zo^2/Zs = 50 \times 50/25 = 100$ Ohms.

Now, at the next "T", we have two 100-Ohm resistances in parallel, giving us the desired 50 Ohms for the RG-8/U. An swr check bears this out. The swr with two elements was a little over 1.5 to 1. With the four elements and the transformers, it dropped to almost 1 to 1. The element lengths and the spacing had been calculated from the following formulas: All ¼-wave elements, length in feet = 246 × .95/14.250 = 16.4 feet. All element spacing, in feet = 246/14.250 = 17.26 feet.

A week of operation proved that the four phased elements equaled the 8-element parasitic beam. Many VKs and ZLs were worked, as well as some long-path contacts to



A view of the array from the highway with our old cattle barn in the background. This view is looking to the east off the back of the array and causes considerable comment among passing CBers. I often notice truck drivers looking out their windows with mike in hand . . . "Got your ears on, good buddy?"

the Indian Ocean, South Africa, and the South Atlantic. Another set of four elements was installed, one at a time, in line and phased, the same as shown in Fig. 3. The second group of four elements was delayed the proper number of degrees each by feeding them off another "T" with a 1¼-wavelength coax line.

The method of power division into eight equal parts is patterned after the way you would divide the power to eight two meter beams. I used this method very successfully in the 1950s on a 32-element beam for 144 MHz. Fig. 4 shows how it is done. No measurements have been made to find out exactly what the power division actually is between elements; however, judging by the array's performance, it must be fairly correct.

Swr measurements with various numbers of elements are as follows: 1 element, 1:1; 2 elements, 1.5:1; 3 elements, 3:1; 4 elements, 1:1; 5 elements, 2:1; 6 elements, 3:1; 7 elements, 2:1; 8 elements, 1.5:1. The addition of a ¼-wave Q transformer, Fig. 5, made up of 2 parallel lengths of 75-Ohm coax, as shown, raised the 25-Ohm output of the last "T" to 56 Ohms, close enough to 50 Ohms to give an swr of 1:1 for the transmitter to look into. Several weeks of tests on the completed 8-element phased array show that it tops the parasitic beam by a good S-unit. This is perhaps because I was never able to get all six directors and the reflector properly tuned for maximum gain. It appears that a parasitic element requires a much more perfect ground plane for tuning than does a driven element. At any rate, the all-driven array was much easier to get going than was the parasitic array. I suspect that an all-driven 4-element rotary beam would outperform a conventional yagi.

Construction

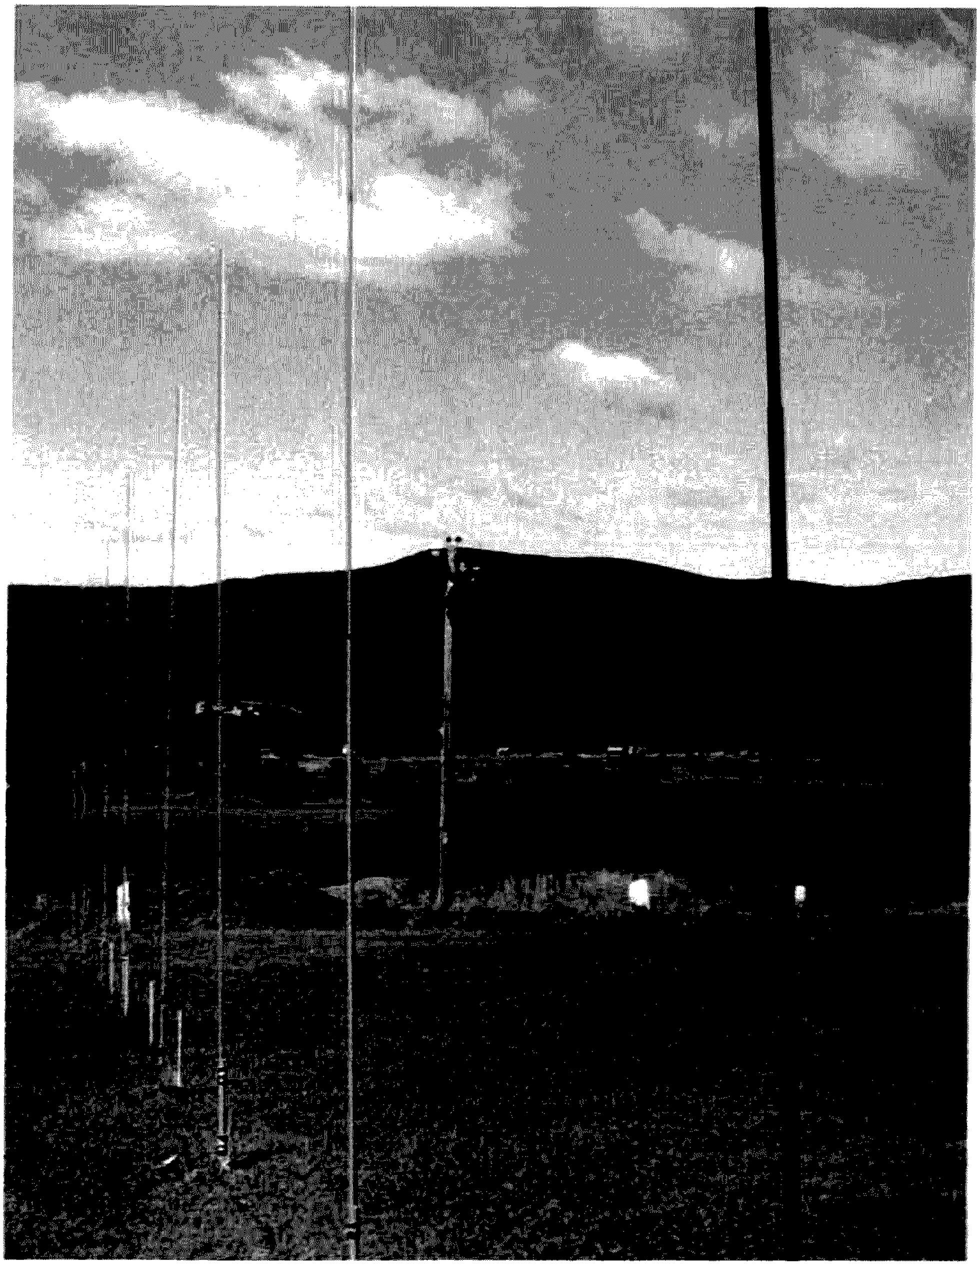
A readily available source of inexpensive tubing for this array is thin-walled galvanized steel electrical conduit, found at most electrical supply houses or discount stores. Each element is made up of a 10-foot top section of ½-inch diameter tubing telescoped into an 8-foot bottom section of ¾-inch diameter tubing. The two sections are accurately measured to 16.4 feet and then fastened together with three 10/32 machine screws tapped into the outside tube.

The ground post is a 5-foot section of 1-inch-diameter tubing driven 3 feet into the ground with a sledgehammer. Be careful to get it exactly vertical using a carpenter's level so that all your elements will line up nicely. Cut off the top 2 inches to get rid of the deformed part caused by the pounding.

The driven elements are each insulated from the ground posts with thick-walled plastic conduit or rigid plastic water pipe.

This is cut into 3-inch lengths and split lengthwise, one size to fit the ¾-inch conduit and one size to fit the 1-inch ground post. See Fig. 6. The RG-58/U is attached to the bottom of the element with a 10/32 machine screw, while the braid, after tinning, is clamped to the ground post along with 16 radials by using a stainless steel hose clamp right at ground level. The plastic insulators are squeezed into place with a C-clamp about 18 inches apart and held there with black vinyl electrical tape until the elements are secured with TV U-clamps.

Remember that the element length is from the top of the element to the point where the radials are clamped to the ground post. Fig. 7 shows the right and wrong way of attaching the radials. Keep the leads on the end of the coax as short as possible, as these add to the length of the driven element. It would be wise to give all the pieces of conduit a couple of coats of rust-proof paint before erection. Also, put corks in the top of each element and ground post to keep out water which will freeze and split the tubing in the winter. Tape the joint of the ½- and ¾-inch tubes with vinyl tape for the same reason.

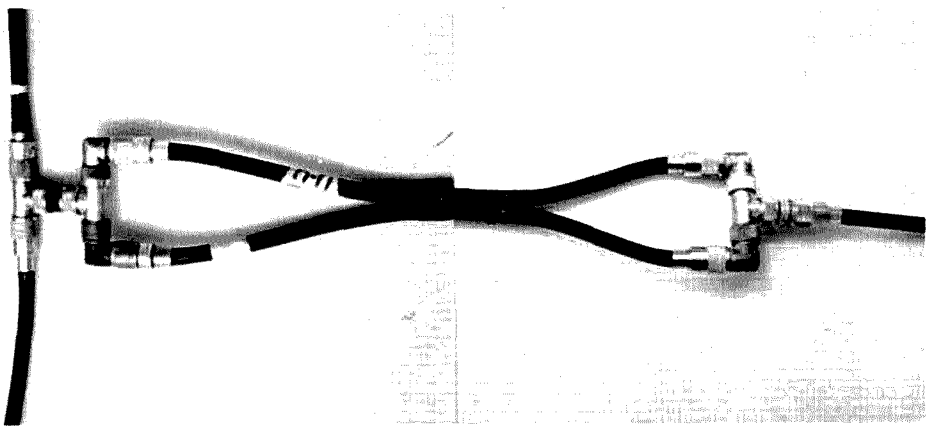


Looking west along the line of the array: The Connecticut River flows in the valley and the hills in the distance are in Vermont. Note that the top of the 7th element is just even with the horizon. A little trig with a pocket calculator tells us that our minimum angle of radiation is about 6 degrees.

Ground Plane

There have been a number of papers published recently[6] on the importance of ground radials or ground planes for vertical radiators. Most of these have been for single-element verticals or for shortened verticals. They have compared the efficiencies of several different ground planes using various numbers and various lengths of radials. A broadcast band station normally uses 120 radials, each 0.4 wavelengths long. If you plan to do this at 14 MHz for each of 8 elements, you will have to bury about 5 miles of wire in your yard, and if you do not want any TVI, you had better solder each place that the wires might touch each other or insulate them well. See Fig. 8. A poor joint will rectify your signal and generate harmonics.

Since I had found no information on the number of radials needed for an 8-element array, I decided to start with none and add them a few at a time until there was no longer any noticeable improvement. You have already read of the disastrous results with no radials and of the improvement as radials were added. If you decide to stop at 16 radials as I did, you will need 16 × 8 × 17 or about 2176 feet of wire, just under ½ of a mile. I bought two ¼-mile spools of #17 galvanized electric fence wire from the local farm supply store for $12. To solder the crossover points before burying the wire, I used acid core solder and then brushed the joint with baking soda to neutralize the acid. The radials were buried a maximum of 1 inch in the sod so that they would not get



This photo shows the use of coaxial fittings in construction of the 37.5-Ohm quarter-wave matching transformer. Refer to Fig. 5 for dimensions. RG-8/U from the transmitter connects at the bottom. The coax leaving the "T" at the top of the picture drives the right-hand and left-hand halves of the array, respectively.

tangled up in the lawn mower. The less "lossy" the dirt over the radials, the better. Fig. 8 shows the layout of the radial system. The dots indicate soldered crossover points.

Coaxial Cable

RG-8/U solid dielectric coax was used for the feedline from the transmitter to the first "T". RG-59/U, 75-Ohm, was used for the 37.5-Ohm ¼-wave transformer, and RG-58/U was used for the phasing harness. Of course, you could use the larger coax throughout if you have it available.

Results

How do you report on the merit of a new beam? The usual method is to set up a field-strength meter and rotate the beam, noting how the field strength varies with different headings. You could calculate the theoretical gain[7] or perhaps program a computer to do it for you. In this way, you could find out what the beam should do under certain conditions. What I wanted to know was what *would* the beam do under *actual* conditions. The only way to find this out is to call CQ DX and see from what direction your answers come. Then instantly switch back and forth between the beam and a fixed reference dipole and a reference ¼-wave ground plane antenna and request the DX station to give you comparative reports on the three antennas.

As a general rule of thumb, the gain of a beam increases by about 3 dB when you double its size. *The ARRL Antenna Handbook*[8] states that a 3-element phased endfire beam has an average gain of 5 dB depending on several variables, while a 6-element beam has a gain of 8 dB. In an attempt to measure the gain of our new array with a homemade field-strength meter with a remote indicating meter, we got a gain figure of 12 dB.[9] In a test with W1PFB/mobile on a hill 20 miles away in Vermont on a bearing of 270 degrees, Glen reported the array was S-9, the Hustler 4BTV was S-4, and the dipole was S-2. At six dB per S-unit, this looks like a 30 dB gain, 1,000 times in power; well, you know how S-meters are. The average VK and ZL station, however, also reports the array 3 to 5 S-units better than the two reference antennas. The proof of the pudding is in the high percentage (about 95%) of answers to CQ DX that come from VK, ZL, and other southwest Pacific Ocean areas.

A possible explanation for the reports of 20- to 30-dB gain at a distance of 10,000 miles from an antenna that should only have a gain of 9 dB is that perhaps its angle of radiation exactly matches the angle of propagation for that distance and that the angles of radiation of the 4BTV and the dipole do not. *The Handbook*[10] states in Table 1, p. 18, that at 14 MHz, signals arrive 99% of the time at between 6 degrees and 17 degrees and

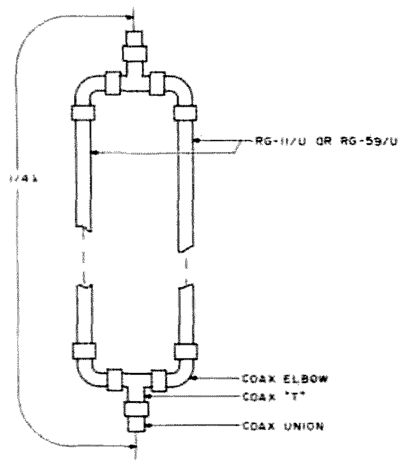


Fig. 5. 37.5-Ohm Q transformer—converts 25 Ohms to 56 Ohms.

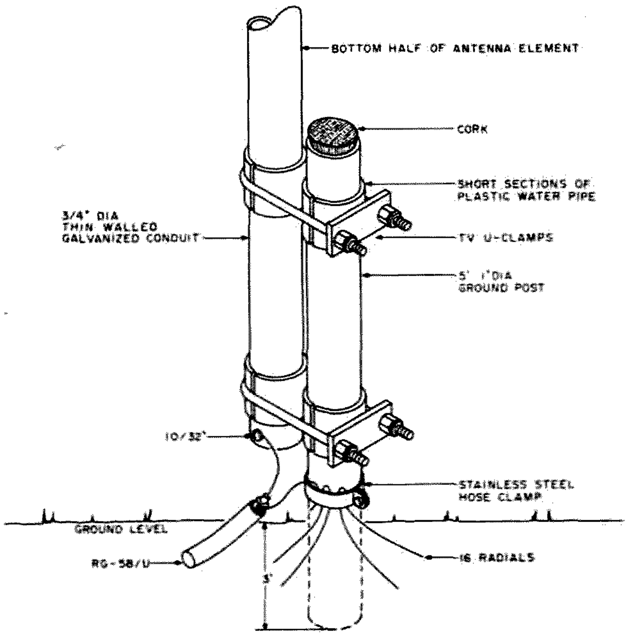

Fig. 6.

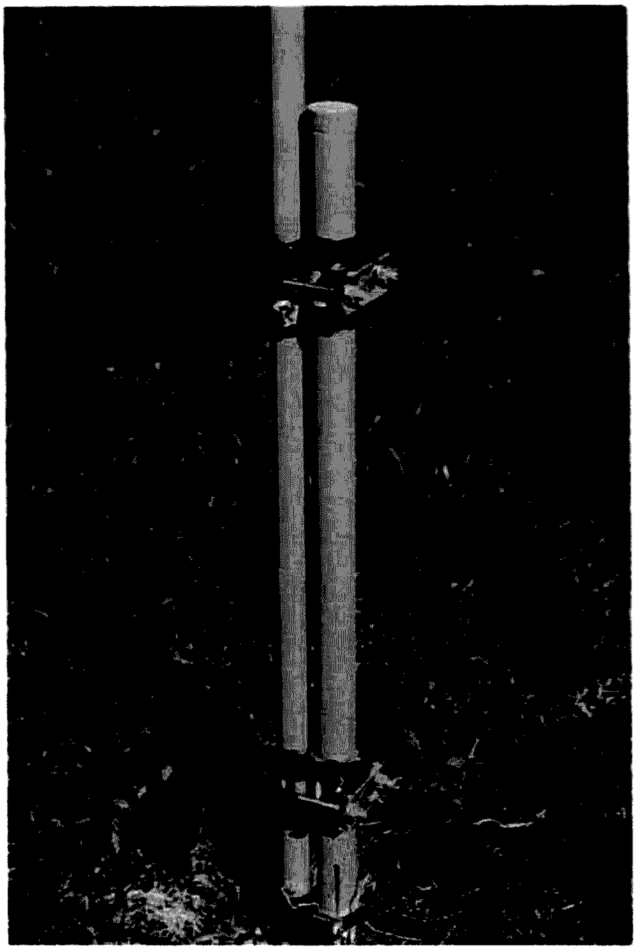

Each of the eight elements is attached to its ground post as shown, using split sections of plastic water pipe for insulators held in place with mylar™ electrical tape and clamped together with TV U-clamps. Refer to Fig. 6.

arrive 50% of the time between 6 and 11 degrees. It is also pointed out that since the maximum single hop via the F2 layer is 2500 miles,[11] a signal traveling from New Hampshire to Australia, 10,000 miles, would require a minimum of four hops. A signal radiated from a dipole ½ of a wave high would have a pattern like that in Fig. 9, with most of its power being radiated at an angle of 28 degrees. It would, therefore, require more hops to reach Australia, and since each hop attenuates the signal, it might be several S-units weaker than the array, thus accounting for the discrepancy in the gain figures between the array and the dipole.

Fig. 10 shows the vertical radiation of a vertical dipole with its center ¼ of a wave above ground. It is believed that a ¼-wave ground plane would have a similar pattern. Note that the effect of ground attenuation absorbs most of the radiation below 10 degrees. My 4BTV has 16 ¼-wave radials, more than usually used, but far less than the recommended 40 radials, each 0.4 of a wavelength long. Therefore, it may have a higher angle of radiation than the array and take one or two extra hops to reach Australia. Thus, with the ground attenuation and the extra hops, it might be even weaker than the dipole, and it appears to be. This same phenomenon, of course, also applies to rotary beams. For example, three identical beams with a gain of 8 dB will each exhibit completely different gains at a point 10,000 miles away, depending on the height at which they are mounted. The one exactly ½ of a wave above ground will be the weakest, the one 1 wave above ground will be an S-unit or so stronger, while the one 1½ waves high will be by far the strongest. At 2500 miles, however, they may be all equal.

Over a three-month period, more than 150 VKs and ZLs were worked, many of whom could not even be heard on the 4BTV or the dipole. QRM from the west is louder, of course, because the array points that way; however, most of these stations are still asleep at 6:00 am Eastern Time. The side-to-front and front-to-back ratios must be fairly good because QRM from Europe and South America is rarely a problem.

If you already have a quad at 60 to 100 feet, this array will not help you. If, on the other hand, you only have a tribander at 35 feet, you may do better in one direction with this phased array, saving the cost of a taller tower. If you are considering spending a bundle for a 60-foot tower and rotatable beam, you may do well to consider two or three of these arrays, each pointing toward needed new countries. Your ability to instantly switch direction with several of these arrays without waiting for a cumbersome rotary beam to turn is indeed a new experience in DXing.

This array, with its method of phasing and power division, may be scaled to other amateur bands. It is possible that top-hat loaded elements could be used on 80 and 40 to keep the height down to 16 feet.[12]

The directional characteristics, both horizontal

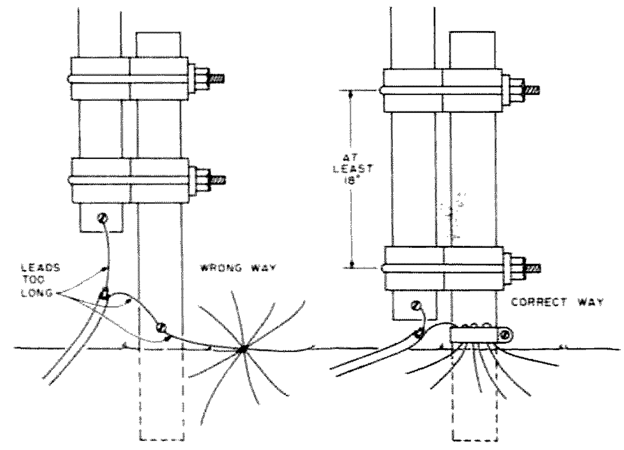

Fig. 7. Right and wrong ways of connecting radial system.

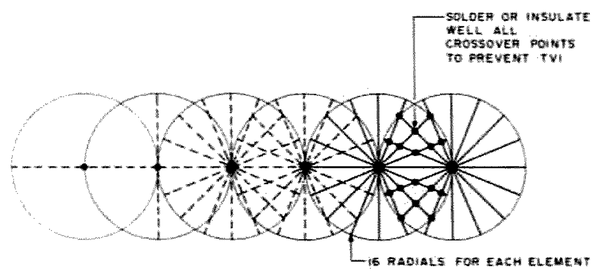

Fig. 8. Radial system shown in full for first two elements on the right. The other six are identical.

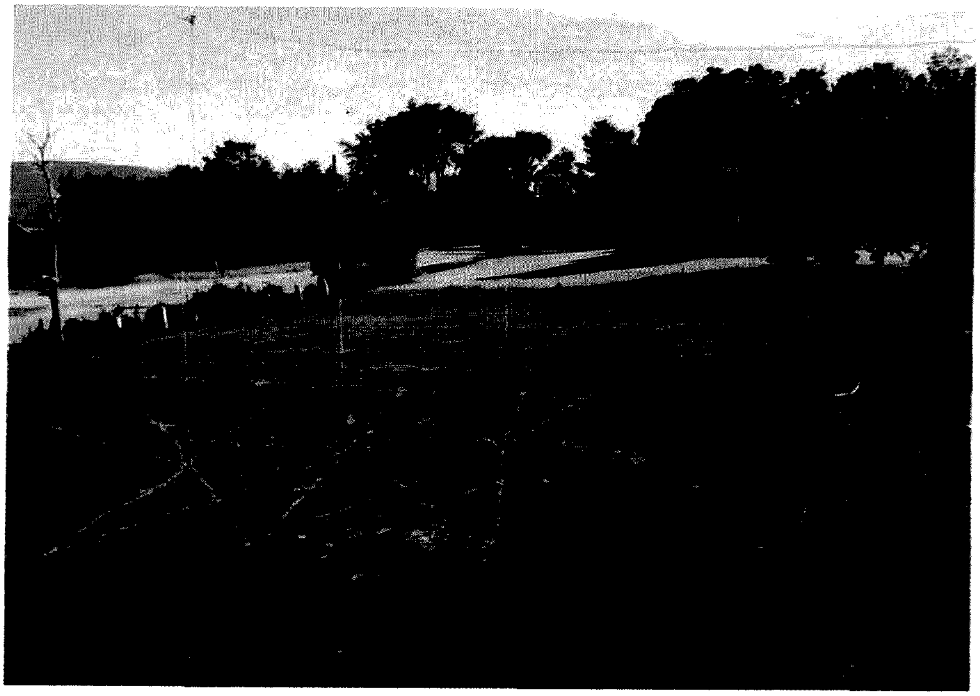
and vertical, of antenna arrays similar to the one discussed in this article may be found in various handbooks.[13]

The direction of radiation of this array may be switched end-for-end or broadside by bringing equal lengths of RG-58/U from each element into the shack to eight single-pole, three-position coaxial switches. Three different phasing harnesses would be switched into circuit.



Four more radials were added after this picture was taken, making a total of sixteen; all were from 16 to 20 feet in length. The author employed a trained mole; however, any sharp-pointed garden-weeding or cultivating tool may be used to scratch the shallow trench needed to bury the radial about 1 inch. Refer to Fig. 8.

Operation of the Array on 21 and 28 MHz

Recently, during a 10 meter band opening, I decided to check the swr of the 4BTV vertical on 28 MHz, and, to my surprise, it was 1:1. I was more surprised to find that the coaxial switch was in the 20 meter array position, not the 4BTV position. Further measurements showed the swr of the array on 10 meters to be as shown in Fig. 11. Next, the swr was measured on 21 MHz. These figures indicate that the array should work on both 10 and 15 meters, and indeed it does. On 10 meters, the swr is 1:1 around 28.5 MHz and is below 1.5:1 from 28.1 to 28.8 MHz as shown. On 15 meters, the swr is 1.3:1 at 21.150 and is below 1.7:1 from 21 to 21.450 MHz. Listening and transmitting tests confirmed that on the ten meter band the directivity was essentially the same as that on the 20 meter band. Signals from the west peaked up a couple of S-units, while signals from the south and northeast fell off a couple of S-units compared to the 4BTV and the dipole. On 21 MHz, the directivity was less pronounced, but the array proved to be effective, equal to or better than the 4BTV or dipole in the westerly direction.

Why does a 20 meter array work on 15 and 10 meters? Terman[7] states that an endfire array consists of identical antennas arranged along a line carrying equal currents excited so that there is a progressive phase difference between adjacent antennas equal in cycles to the spacing between these antennas in wavelength. He further states that the gain of the array is proportional to the length of the array, but is independent of the spacing of the elements provided that the spacing does not exceed a critical value of about 3/8 wavelength. Greater spacing is permissible under certain conditions. The array being described fulfills the above conditions on 14 MHz with a 90-degree phase lag and ¼-wave element spacing. On 21 MHz, using the same phasing harness, the phase lag becomes 135 degrees with the 3/8-wave spacing between elements. On 28 MHz, we have a 180-degree phase lag with ½-wave spacing. In other words, the phase lag between elements is correct for the element spacing on each of the three bands. The element lengths, however, are incorrect on 21 and 28 MHz. On 21 MHz, the elements are 3/8 of a wave long, as are the ¼-wave Q transformers. It is not quite clear why it works as well as it does on 15 meters. On

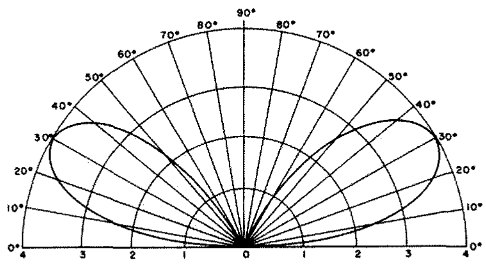


Fig. 9. Vertical angle of radiation of a half-wave dipole at a height of ½-wave above a perfectly conducting ground.

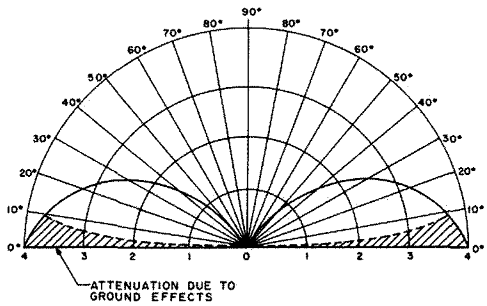

Fig. 10. Vertical angle of radiation from a half-wave vertical antenna whose center is ¼-wave above a perfectly conducting ground.

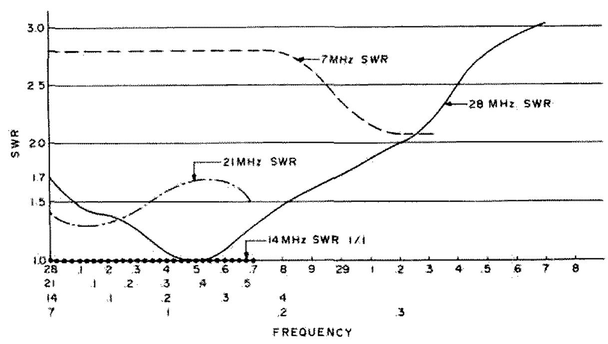

Fig. 11. Swr curves for 7 MHz through 28 MHz for the array.

28 MHz, where the elements are ½ of a wave long, it would appear that we are trying to feed a high impedance point with a low impedance feeder. There is undoubtedly a very high swr on the coax nearest to the elements. The losses will be low since the coax is short. Since our ¼-wave Q transformers are now ½ of a wave long, they no longer act as Q transformers but simply repeat the impedance from one end to the other. At each "T", we parallel these impedances and cut them in half, thus reducing the swr as we get nearer to the transmitter. Terman shows that the gain with ½-wave spacing is only about ½ that of ¼-wave spacing; however, since the array on 10 meters is twice as long as it is on 20 meters, the gain doubles and therefore is about the same as on 14 MHz.

P.S. It works like a bomb on CB. ■

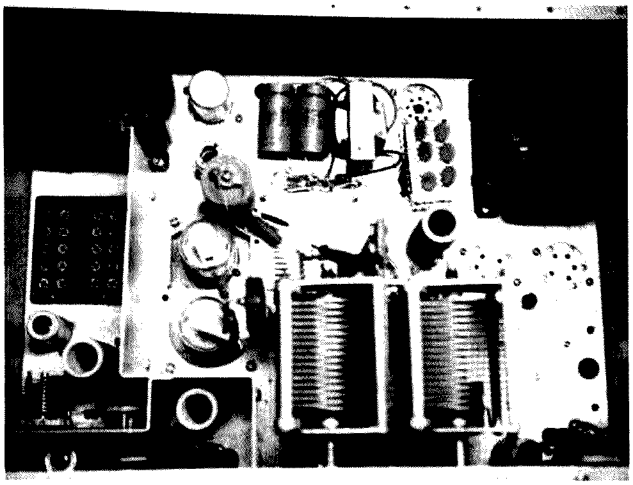
CW with a Nordic Flair

—new life for the Viking I

Butcher your boat anchor.

For the CW op who is looking for a respectable signal with minimum cash outlay, here's a chance to put a quarter kilo on the bands for about two bits per Watt.

The recipe for this treat has, as its main ingredient, one of the old boat anchors that were "in" before the advent of the filamentless tube. We refer to rigs in the Viking class which can be acquired at hamfests for anywhere from \$30 to \$100. Prices generally are inversely proportional to the algae accumulation, that is, the more shine outside, the higher and bigger the ticket. I can only encourage prospective buyers not to worry about outside rust, dents, and scratches, but rather to get a close evaluation of the innards, mainly the power transformers and rf section.



When I acquired a Viking I, the cost of the rig was less than the follow-up chiropractic costs from hefting this unmobile monster. So, numero uno for the mod squad was a requirement to trim, slim, and debulk the critter. If you have a Viking, compare it with the photograph which shows a lot of gaping space left when we retired from surgery.

I don't have any "remove the third bolt and cut the green and white wire three inches from the end" type of description for these mods. But take heart and use judgment and a certain amount of caution. It's your rig to butcher as you bloody well please, so you're the only judge of what you do. An old friend used to assay his home jobs in two categories—for fun or for sell. You won't have much of a shot at selling it, except on performance, so have fun like I did.

Check the circuit of the unmodified power supply. There are really a powerful lot of iron components floating around, iron that means good design but is not really needed in a strictly CW machine.

Transformers T1 and T2 are needed, of course. But chokes L1 and L2 were promptly relegated to the junk box (which is one way to build up one of those junk boxes that builders always seem to have). These chokes serve to smooth out the ripple in the outputs of their respective power supplies. You learned about them studying for the General exam without getting involved with more complicated stuff like $E = L\,(di/dt)$, which has to do with the notion that a changing cur-

rent through an inductor causes a back electromotive force (emf). The back emf tends to oppose the change in voltage trying to take place, with the net effect that one tends to cancel the other, particularly when load demands change, as in modulation. So, instead of a changing voltage at the rectifier output (a ripple), you get a smoother dc voltage, which is why it's called a smoothing choke.

Those chokes are fine for ten meter phone rigs, but, since this is a CW rig, we care less about phone and don't need the super design of smoothing chokes to get a T9 report.

But something is needed in there to work with the filter capacitor, which turns out to be a series resistor. L1 was replaced with a 200-Ohm, 50-Watt resistor, and L2 with a 500-Ohm, 25-Watter.

From there, I moved over to the audio section, and, in a flash, two more big hunks of iron, T3 and T4, passed on to the junk box, probably never to rise again, since these are the modulation and interstage transformers.

Right about there is where paring the iron takes some steely nerves, because it's a no-return point. Those transformers go and so does any phone mode. You could always sit back and rationalize that you just might like to take a whack at AM some day and all that. Well, that's your decision.

Without the transformers, there wasn't much sense in leaving the audio tubes in their sockets, so out they came, at a saving of 15 Watts of filament power.

Meanwhile, back at the power supplies, further mods were made. It was with some pleasure that I relegated the rectifier tubes V8, V9, and V10 to the junk box, saving another 30 Watts in filament power. Solid-state rectifiers were installed.

The low-voltage power supply was converted quite simply with a plug-in replacement, the 1N2389. But you don't have to go to that expense. Use a pair of diodes in a full-wave circuit from the *Handbook*. Type 1N4006 diodes rated at 800 volts, 1 Amp, are advertised at 15 cents each. Buy a bunch and run some front-back resistance measurements to select the best with the highest back resistance.

I went to a three-diode series arrangement shown in the diagram, using three of the 1N4006s to get a safe peak inverse voltage level of 2400 volts in the high-voltage power supply. The shunt resistors and capacitors are there to protect the diodes in case one of the critters has different characteristics than the others and might take an ungainly bigger slug of peak voltage. That would have you back in there with the soldering iron right soon. The *Handbook* also talks about this situation.

The high-voltage rectifier was built on sandwiched pieces of perfboard and wired to an old tube base (that I happened to have in the junk box) from a discarded 5R4, and that just plugged into the old 5R4 socket.

After all these chops, the net change was to have cut out four chunks of iron and seven hot bottles, which was a significant weight and power reduction. I went back in to add a small 24-volt transformer, rectified with another pair of those 1N4006s, and regulated by a small 15-volt solid-state voltage regulator (Radio Shack has them for $1.50). This supply is intended for a vaguely-distant outboard FET vfo (one of these years). A VR150 was also added to the screen grid of the oscillator, and an antenna relay was thrown in for full break-in.

The first thing I noticed on firing up the rig was a hefty slug of plate voltage, well over 800 volts. Just to bore you a bit as to why there was so much more soup over the nominal

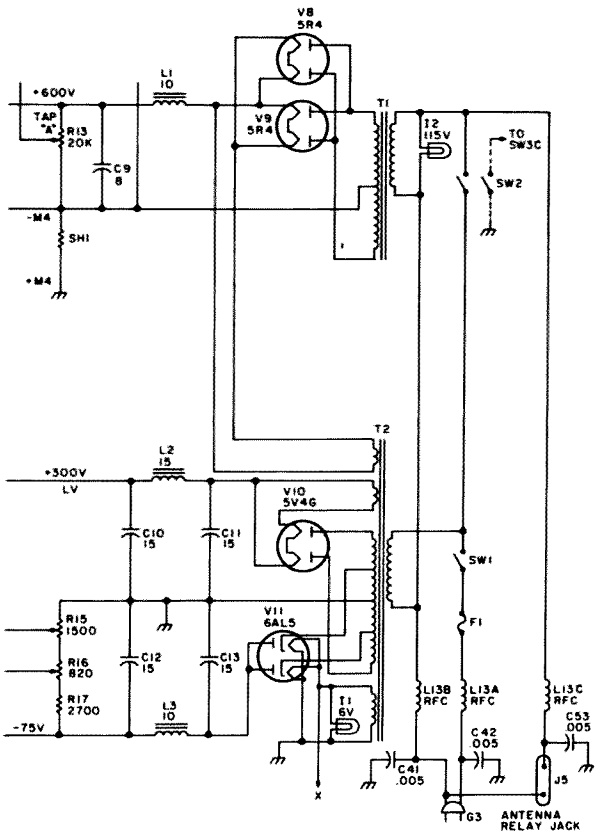


Fig. 1. Original Viking power supply diagram.

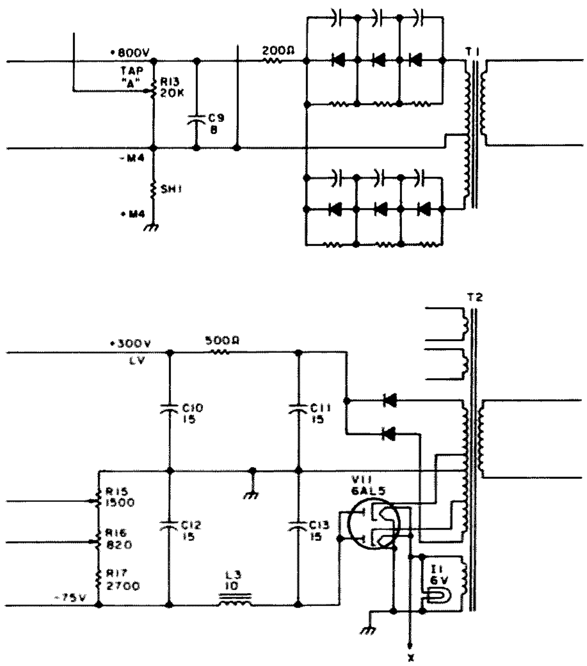

Fig. 2. Modified diagram. Diodes—1N4006s. R—1 meg. C—.01 μF.

600-volt former value, it was the replacement of the vacuum tube rectifier with the more efficient solid-state rectifier. In the theory of vacuum tubes, there is that characteristic known as the tube's dynamic plate resistance. This is a simple cut at Ohm's law, which says that anytime there is voltage across a gadget through which current is flowing, that gadget has a resistance. More properly with respect to a tube, a changing voltage with respect to a changing current gives a changing, or dynamic, resistance. Trouble with the tube is that its dynamic plate resistance can't drop as low during heavy conduction as the semiconductor's can, so the voltage across the tube is voltage wasted. Since the semiconductor doesn't have that kind of hang-up, very little IR drop is across the semiconductor under heavy forward conduction and all the soup goes into the pot, right at the final plates. (Our low value of resistance in the filter also helps.)

Also noticed real quick-like was the way rf zapped around the plate tuning capacitor. There's a lot more rf kicking around the final with higher voltages, and you really have to be careful in tuning. Had I not buttoned up the rig and gotten subsequently sidetracked, the smart addition would have been a switchable resistor in series with the screen grids to the final. I felt bad about this one getting by and strongly recommend breaking the screen lead to insert a 10k or 20k resistor in series with the present dropping resistor. Then put a switch (use the old phone-CW switch) across it so that for tune-up the switch is open and you're in QRP with low screen voltages.

With over 800 volts on the 6146s, you shouldn't walk away with the key down. You could get some experience with cherry red plates by holding the key down for a while (properly loaded) and observing. The rule under such is: red, si; blue, sick. In other words, a cherry red (I don't know why they always say "cherry" red) on the plates won't hurt, but a blue glaze or glow around the envelope when you key is a no-no. It means the tube is gassy and will do unpredictable things. You could get away with using it on 80 and 40, but on 10 or 15 you might well be in trouble (as I was when my blue final brought in a pink QSL once). Best bet is to learn exactly what the dials read when the rig is properly tuned for your antennas on each band, then log those readings. Next time you QSY, go right to those readings before keying down.

The 6146s were loaded to 300 mA with no problems to get that quarter kilowatt. There is occasional arcing, but that's a fun experience that you don't get every day. Fact is, if you had a new checkbook rig and it dared to arc over, you just might have a mild coronary. But with an old clunker like this, what could be more typical ham fun than disturbing the quiet of a pre-dawn QSO with a companionable splat-t-t-t on a long dah. Shucks, that's how you store up memories for the day you join QCWA.

In summary, here's a rig with certain anatomically connotative improvements—it didn't cost an arm and a leg to get a quarter kilo on the air, it doesn't quite break your back to heft it around, and you don't have to sprain your wrist writing out a check for the electric bill. ■

House-Hunting for Hams

—caveat emptor!

Avoid nasty surprises.

Consider the sad tale I heard on 15 meters the other night.

A ham and his XYL, along with their real estate salesperson, went looking for a new house. In the car, he explained the kind of house he wanted and said that he was looking forward to having his first full-fledged antenna farm. They found the dream house in a fairly new development. He didn't notice any antennas on roofs, but it was early spring and most people had moved in during a long, cold fall and winter. To be safe, they drove by city hall and got a copy of the ordinance pertaining to towers. Everything looked OK. They bought. Months passed. As he was laying out the parts to a 65-foot tower in the backyard, a neighbor casually asked what he was doing.

To his grief, to his agony, he was told that the homeowners association had a rule against all external antennas.

He is not the first ham I, as a real estate broker, have counseled, either on the air or in person, about buying a home. But for him it was too late. He is now reading articles about "cliff-dweller" antennas, and "how to work the world on your attic antenna."

His first reaction, of course, had been, "Can they do that?"

You'd better believe it! In this case, the builder founded the association with the intent of keeping property values at some high common level. It's a great idea for 99% of the people, but for our friend it was tragedy. Buried in the mounds of paper accompanying the normal real estate transfer was a deed restriction giving certain rights to the association regarding the grounds and exteriors of the homes in the subdivision. One rule restricted antennas.

Let's understand one thing right away. There are many ways to get fouled up when buying real property, and new ones are being invented every day. Self-servingly, but realistically, I recommend a trusted broker. You may need to talk with several to find the one you want, but when you do, show your trust by listing the whats and whys of your property needs. Then stay with that broker. He/she will work hard for you and chase information if he knows he'll get paid in the end.

Consider the following in your early discussions with the broker:

1. Homeowners associations. Don't think that townhouses and condominiums are the only places that can restrict you. Many single-family areas of all price ranges have these associations or are attempting to form them. Even the voluntary ones exert peer pressure on non-complying owners. Many times they will have an architectural control committee that can cite you for such things as the wrong color door, a trellis extending above the fence line, or unacceptable installation of children's swing sets. Just try to get them to let you have an 80-foot tribander! I still think associations are a good thing. They do tend to keep values up, and most are reasonable. But I don't know of any allowing what hams dream of.

The listing broker should have information about mandatory or voluntary associations, but if not, your broker can contact the association or its management agent, if there is one.

2. Restrictive covenants (deed restriction or condominium declaration, if any). "Condominium" pertains to a form of ownership law, not architectual arrangements. Many single-family detached homes are coming under the condominium law. I once sold a house that was not under condominium law but had a 1908 deed restriction regarding the size and cost of the outhouse. We found it by checking the records at the county recorder's office. The existing title policy (or other evidence of title in your area) should indicate the existence, but not necessarily the nature, of restrictions. In a subdivision, at least in our area, you can check the documents filed when the division was made and be pretty safe. In non-divided areas, you must check the documents filed on that property.

3. Zoning laws or building ordinances. Most of us are familiar with the battles that hams have had nationwide to keep these laws fair to all. Be care-

ful—just because someone has a tower nearby, or just because one went up recently, does not mean it was legal then or now. Taking down is less fun than putting up.

4. Building permits. In some cases, you may even be required to appear before the town council. You may be restricted as to height, distance from property lines and power lines, and crank-up towers may be allowed only on Tuesdays when the moon is full. That is my way of saying that town councils and those that serve them are very creative when they write laws. The only way to know for sure is to get a copy of the law and ask someone there how they enforce it. You will not find that person in the day you call. In fact, he'll probably be the eighth person you talk with on the tenth day.

Knowing what to look for and being sure are two different things. Start by having a conversation with the broker about your regular home needs. (How about 4 bedrooms, 2½ baths, family room, full basement, 2½ car garage, at least an acre of yard, for not over $35,000? This is a little real estate humor, since that home sells for over $100,000 in our area—but these calls still come.) Then tell about your special needs—some of which will follow. Mention the problems as above. Discuss local areas.

If you are new to the area, contact the ARRL for a list of clubs there. Or get on two meters and find out what the local problems have been from the people who know. But remember, *they* may not be aware of some of the hidden restrictions, unless someone has had a specific problem in that subdivision. (And then, too, some subdivisions have more than one association.)

If you decide you want or need an attorney, find a good *real estate* attorney (the broker can help you). I prefer a local one who knows the area. Get some wherefores and whereas to add to the standard sales contract. They might take the form of a rider making the sale subject to no association, deed restriction, or building/zoning ordinance prohibiting you from doing whatever it is you want to do, or a rider voiding the sale if a building permit to construct (insert what you want) cannot be obtained in some reasonable time. I know many people don't want to spend money for an attorney. Most transactions go rather smoothly for the buyer without an attorney. But on those that don't, it's generally too late for one to help after you find you need one. It's better to get one up front.

Now that you have a broker and attorney working on your behalf, you should monitor their work. Even if you don't understand the law, you can make a judgment about their thoroughness. Ask questions. Remember, they are getting paid to answer your questions. Ask about every aspect of the transaction, not just ham-related ones. If they can't answer, won't answer, or don't try to get the answers, consider someone else.

Here are some more things to check: electrical capacity (verify amperage, but not by counting fuses), wiring (among other things, aluminum wiring was popular at one time and if not installed properly is a fire hazard), elevation (topographical maps, flood plain maps, and elevations-above-sea-level are available through the broker or city hall), power lines (do you really want to live under high-tension lines next to a sub-station?), airports (remember height restrictions), common television antennas (the preamps in these small systems pick you out of the ether better than channel 2), and look for a suitable quiet room away from the family traffic pattern (hi, hi).

One amazing thing I notice about home buyers is that they seldom walk the grounds. Walk all over the yard. Plot antennas as well as geraniums. Get a copy of the survey and plan the future. If the market is fast, the house might be sold before you get that done. Having the attorney prepare safeguards on a rider, prior to looking, gives you the ability to move rapidly even if you are not finished checking everything out. Once you sign, it's too late to ask about towers unless you have caused the contract to give you that right over the next few days.

Perhaps it will never happen to you. Some old deed restriction from a farmer in 1898 won't crop up (did I really write that?), and you'll always luck out, and your only worry will be airplanes dodging your guy wires. Maybe you've bought and sold ten homes and had no problems (Murphy's Law times ten squared), but a little work by you and your broker can make sure you'll get what you want.

Finally, ask about financing. Some of the new plans permit less down payment, but the monthly payment is still affordable. Since less is needed up front, you'll have more available for furnishings such as refrigerators, amplifiers, stoves, transceivers, dishwashers, and so on.

When you get the tower up and have a stacked array on top, give me a call on 15. We can all use the good news! ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

waiter asked me if I was a ham. I nodded and he asked my call. Just to be smart, I tilted my belt buckle up and read the engraved call . . . W2NSD/1. The waiter laughed and introduced himself as Fred Scully WBØFOR.

Since most of us had our HTs with us, Fred clued us in on the repeater in nearby Glenwood Springs . . . 146.67.

The next day, while we were having lunch at the Tiehack restaurant side of Buttermilk Mountain, I tried out my Tempo S1 HT and switched to 67. Sure enough, I raised the repeater and resident user Bob K9MWM. We talked while I ate the delicious pea soup, and then I asked Bob what kind of business he was in out here in a small Colorado town. I just about lost my breath when he said he was writing computer programs for the Radio Shack TRS-80 and selling them to local businesses. It turned out that he reads both *73* and *Kilobaud Microcomputing.* You can be sure that Bob joined us the next day for skiing.

It appears that Instant Software will be able to distribute some of Bob's business programs, so by next year he may have considerably more leisure time for skiing. How many small towns around the country harbor a programmer writing microcomputer business programs? That's just too much of a coincidence.

Sherry Smythe, with all those Aspen trees for which the town is famous in the background.

On the following day, our Denver legal staff drove in and we had a great time spending a full day hashing over growth plans with them. I've long had the desire to take *73 Magazine* public so that the readers would be able to own the magazine, but every time I've approached professionals about this, they have pointed out that it is necessary to have five years of certified bookkeeping before this can be entertained.

Now, with a new corporation (Instant Software, Inc.), perhaps it will be possible, once the corporation shows some significant signs of success, to take it public. Our lawyers seem enthusiastic. It would be fun to be in on the ground floor of something with the growth potential which software publishing seems to provide. Watch out, Xerox!

Between the software, the talks with manufacturers and dealers, the legal discussions, etc., the conference at Aspen was a great success. The skiing was fabulous, the meals ditto, and the company first rate.

Funny thing. I got a beef about the conference last year. One chap showed up with his wife, attended one dinner, and was not heard from again. His employer was bent out of shape at me for this! The purpose of the week-long conference is to get industry people together in a relaxed atmosphere and have ideas discussed on marketing, advertising, the future of amateur radio, etc. Discussions somehow seem to go better when you are on a ski lift together . . . eating lunch on a mountaintop . . . in a sauna . . . or having dinner at a superb restaurant.

While talking over my HT from the center of town, I was stopped by a chap who asked me the repeater frequency for Aspen. It seems that he'd read in *73* about the conference, but his wife wouldn't let him talk with other hams while he was there, so he wasn't checking in with us.

ARRL BLOWS $100,000?

Several of the insiders at the League are bent out of shape over the recent dumping of about 50,000 1978 ARRL *Handbooks*. I gather that the people wanting to blow the whistle first turned to *HR Reports*, but got nowhere. I don't know any good way to check all these allegations out, but perhaps you can get some straight answers from your directors the next time they talk at a hamfest or convention.

It appears that the chap in charge of ordering *Handbooks* made just a little mistake in 1977 when he ordered 30,000 more than the League could sell. No one seems to know just what happened to these 30,000 *Handbooks* or who collected for them.

At least someone seems to have learned by experience, for in 1978 they ordered 50,000 more than they could sell. Now, in the book business, it is not unusual to have some books left over, so publishers send out a letter asking for bids on overstocked books. In this case, where the book was selling for $6 and perhaps selling wholesale for $4, ham stores around the country probably would have jumped to buy out the lot at $3 per book. Since they probably cost around $2 to print, the ARRL still would have come up a winner.

This doesn't seem to have happened. I know that our Radio Bookshop, one of the larger sellers of radio books, never got any word that the *Handbooks* were available . . . and the larger dealers that I have talked with got no word of the brewing deal. What seems to have happened, if I can believe sources within the ARRL, is that some of the *Handbooks* were sold to Herbach and Rademan for $1 each . . . an excellent deal for H&R. The rest of the 50,000 were apparently given to *Ham Radio* magazine to be sold . . . and not for a cash-up-front payment, but on consignment. This means no investment at all for *HR* . . . with the price alleged to be the same $1. Now, if that isn't a sweetheart deal! I think I could have moved the whole 50,000 out to dealers at $3 each on a lovely deal like that.

The end result looks like the ARRL took a bath on the *Handbooks,* losing about $100,000 that they could have netted if they had had anyone with brains running the show. Of course, if there are other factors . . . like a hand under the table somewhere . . . ? And ARRL staffers are still asking what happened to the 30,000 books from 1977 and who got the money for them.

Then there is the case of the missing operating aids. Ten thousand were ordered from the printer and paid for, yet only five thousand were ever delivered. Where did the others go, and who sold them where for how much? I understand that this situation was detected but never investigated. How about asking your directors?

With a hundred thou going here and another there, kind of leaking through the cracks, perhaps it is time for getting rid of the Good Old Boys who are running the HQ and making a mint at it.

Members might ask their directors why they let the same old people run the show when even the old-time staffers are bailing out of the sinking ship. I understand that Bob White left when he was forced out over a DX decision by Baldwin. A lot of years went down the tubes . . . and Bob was about as straight a chap as amateur radio could ask for in the job. His wife apparently left when she could no longer stomach shady doings with new products. So I'm told.

The result of the recent staff changes is that virtually no one on the day-to-day staff has been there more than a couple of years. The pay is poor for the staffers, but they have to put up with what appears to be heavy-duty graft on the part of the Good Old Boys . . . things like having books published by outside publishers using *QST* material . . . trips with a secretary instead of a wife, all paid by the ARRL.

One whistle-blower suggests that I ask for a revelation of who has stock in VBC. The scenario does seem strange . . . first an editorial in *QST* saying that a breakthrough is needed . . . then some articles on NBVM which don't tell how it works, and a 1979 *Handbook* chapter on the system showing a working unit which has never even been shown at HQ. With both the FCC and the communications industry turning thumbs down on the NBVM system, you may be sure that I'll be most interested in how it really works once some units are made and shipped.

I've tried to get some information from the promoter of the effort, Tommy Lott, but have gotten silence for my trouble. This set me to wondering about whether the whole idea was more of a promotion than a breakthrough. It would be comforting to have a disclosure of who owns the stock in the firm and to find that no one at ARRL HQ is listed.

TIME TO SPARE

Recently, I had to make a quick business trip to New York. Having lived in the city for 30 years, off and on, I normally avoid it like the plague that it is. I kept track of the time it took me to get from Peterborough to my destination in Manhattan . . . and I cut things as close as was practical.

I left Peterborough at 0820 and arrived at Logan airport in Boston at 0950. I got right on a

plane and arrived at LaGuardia at 1050. By 1115 I had arrived at the subway station and was on my way to Manhattan. I arrived at my destination at 1200. Now, if I'd driven directly to New York, I'd have arrived at about 1220. I saved 20 minutes and spent a bloody fortune on the plane.

While going past the 61st Street Woodside train stop, I got to thinking back a few years to my visits there with John Williams W2BFD. John died in 1961, and I picked up some of his old equipment at the auction—I still have it around here.

John was the primary pioneer of amateur radio Teletype™. He got going with this back in 1946, and he provided most of the circuits and equipment for the entire hobby for the first few years. John ran this sort of side business out of a grubby little storefront shop in Woodside, Queens ... a radio repair shop. You remember radio? This store, usually closed, made enough for John to support his hobby of RTTY, and that's all he wanted. He designed most of the equipment we used, set the standards, made the templates, sold the parts, and generally nursed this hobby along.

John also got into trouble a lot. Ma Bell was very uptight with him because he had rigged up an automatic telephone-answering device in his store and wouldn't let their inspectors come in to see how he'd done it. They were sure that he was connecting directly to their wires, but couldn't prove it unless they could get in to inspect. They would always find the store closed.

He did indeed connect to the verboten Bell wires and had a corking-good answering system going, years before it was popular. He could talk over the phone from his home a mile away via a carrier current system. The phone-answering system used a phonograph record to give his message and a wire recorder (remember *them*?) to record the response. He was generally monitoring the call from the shop or home and would break in if he wanted to talk with you. You ran into the same problem at the store door ... with an intercom speaker which went via carrier current to his home ... and a similar system at home going to the store. You just were not about to be able to locate John if he didn't want to be located.

I remember the day the FBI came to my house to ask questions about him. That surprised me. All I knew about were his radio repairs, the RTTY involvement, and his problems with Ma Bell, so I couldn't have helped them if I had wanted to. A few years later John confided that he had been involved with a good deal of building and using of bugs, telephone and otherwise, and that this was what the FBI was wanting to know about. He had made a system which the Arabs had put into the Israeli cars in New York to allow them to follow behind and hear what was being said in the cars. I think he also got into telephone modifications which would allow the radio transmission of phone calls over a short distance, a concept which interested the Arabs, too.

The income from these efforts probably went more to keep him going than the radio repairs, as I seldom ever saw him doing any radio repairing. And most of the stuff in his store was RTTY gear, not radios in for repair.

John, with my help, set up the first amateur radio two meter repeater in the country. We set it up on top of the New York municipal building in downtown Manhattan. I will never forget putting up the antenna for the repeater in the middle of the night in a blinding rainstorm—with me up there on a very steep copper roof, holding on to little pegs here and there to keep from falling about 20 stories. I was in my mid-20s at the time and often did silly things like that in the interests of amateur radio.

There was, unfortunately, a slightly crooked side to John, too. I don't know how many hams sent him money for Teletype equipment which he never delivered. It was petty larceny, but aggravating to those of us who knew him and appreciated the extent of his genius. John, at that time, had a virtual corner on all used Teletype gear, so if you didn't buy it from him, you didn't buy it. We were buying Model 12 Teletypes at that time ... somewhere in my barn I have John's old original Model 12, in case there is an opportunity for a shrine to this pioneer to be erected. I also have a couple of the complete W2BFD systems which I built, with auto-start and -stop. They were quite modern, except for the use of dozens of tubes in each one.

Amateur Teletype, when I got interested in it over 30 years ago, was stuck up on two meters (and 11 meters), and we had about 30 stations working all on one frequency in the vicinity of New York. We were on 147.96 MHz using 8220 kHz crystals with SCR-522 systems, for the most part. Using audio frequency shift (2125/2975 Hz), we could leave the receivers on all the time. Our printers would start up if a standard start signal was received ... a couple seconds of mark signal. A steady space signal would turn everything off.

Some of the fellows left their receivers on all the time, while others hooked them into a small clock which sampled the frequency every hour for two minutes. We could then leave messages with anyone by sending the start signal for one minute during this window. I left my receiver on all the time, wanting to keep track of what was happening when I was away from home. I'd come home after a weekend to find a hundred feet of paper on the floor, filled with chit-chat and messages.

A few of the fellows had an automatic confirming system. They put a microswitch behind the Teletype carriage so that it would turn on when the carriage was in one particular position ... say, the tenth letter along. This would turn on the transmitter filaments and warm them up. Then, after a minute in that position, the release of the carrier would trigger a double pulse of the confirming transmitter as a "roger" that the message had indeed been received. Of course it wasn't exactly legal, but then what experimenting is?

Oh, on the repeater, it enabled all of the RTTY hams in greater New York to keep in constant touch and was fantastic. The FCC put it off the air after a few months. They didn't like any automatic relay systems like that. If we could have an operator present, OK, but otherwise, no go.

It was RTTY that got me into this whole ham publishing mess. I started out in 1951 with a monthly newsletter to RTTY hobbyists ... now look at it!

GRABBING THE BUS

One of the more innovative concepts which microcomputers have introduced is the idea of using a bus structure for electronic circuits. In the case of computers, this means that all of the significant signals are made available to every board

John Williams W2BFD, on the left, about 1954. I forgot the chap in the middle, but the right-hand chap is Doc W2BIV, a Brooklyn dentist.

John again, taken during a RTTY meeting about 1954. We'd often get a dozen or more RTTYers out to these meetings.

plugged into the bus. The board can then avail itself of any needed signals with no further interconnections needed.

Could such a concept be adapted to the ham transceiver? Well, let's suppose we wanted to build our system in a modular way and then make any needed connections for accessories available via a bus. We might have on the bus the +5 volts for logic circuits, +12 for control and power circuits, audio for earphones, audio for speaker, mike input, i-f input, i-f output, local oscillator, AVC line, etc.

With that array of signals available for accessories, we could design boards for interfacing SSTV, for RTTY, for CW encoding or decoding, for audio filters, a flying noise lock, synchronous detection, a keyer with memory, VOX, automatic ID, a panadaptor, an autocall unit, programmed tuning, a phone patch, a voice processor, a cassette recorder, a two-tone test, a CW regenerator, etc. There are many possibilities which such a flexible situation would open up for the super transceiver of the future.

This type of structure would make it possible to buy a barebones transceiver and then add plug-in modules as money and technology permit. It would make it possible for the CW fan to get any bandwidth i-f desired, add audio filters, a regenerator, and end up with an incredible CW receiver. The weak-signal VHF CW experimenter could narrow down the i-fs, put in the filters, a flying noise lock, a recorder, and all those things which this strange craft requires.

The Saturday afternoon ragchewer could have his system monitor any set of channels for calls from friends, all done automatically ... complete with a beeper alerting call on a VHF band, if wanted.

How much further would such a system have to be pushed to decode CW signals and look for expected DX? No strain ... and the next step, with such a structured system, would be automatic DXing.

AUTHOR PREROGATIVES

One of the publisher's newsletters mentioned that writers can charge off magazine subscriptions as a business expense. That makes sense ... and might be just another reason to become a professional writer for the ham magazines ... such as *73*.

As a professional writer, your expenses would include the cost of any equipment you have built or reviewed ... costs of your writing office, reference works, test equipment, etc. It's worth checking out with your tax accountant.

What kind of articles are we looking for at *73*? First choice goes to state-of-the-art projects ... perhaps a microprocessor-run something hammy ... small and medium construction projects are always popular. It's difficult to get too much in the way of home-built equipment articles, antenna articles, microcomputer articles ... just about anything on new techniques and modes. We need more on satellite equipment and techniques ... AM on ten meters ... new RTTY equipment ... even very low frequency articles are of interest.

I'm always on the watch for any really hot new aspect of amateur radio which I might be able to use to get thousands of amateurs interested and involved. Look what happened when I plugged the devil out of two meter FM and repeaters! This can be done again if something with good possibilities comes along ... so if you think you've got it, please start writing and let's see if it flies.

This ambulance is at the ready to cart away hams who totally lose control over the low prices at Tufts Electronics. They get a free trip to the foam-rubber room of the local funny farm until they are signed out by their wives.

Writing for *73* isn't very difficult. Remember to double space your typing (please type it), do not use all capital letters, and get me the very best pictures you can.

WEIGHTY MATTER

There are, I understand, several dozen *73* readers who have no problem with their weight ... and possibly a few of those with wives with no concern about weight, though this seems unlikely. What this all comes down to is dieting ... at least every now and then. Erma Bombeck classifies "diet" as one of the dirty four-letter words, and I tend to agree with her.

Heath has come out with a very nice electronic scale (the GD-1186) for the bionic people. It reads to a tenth of a pound, which is fabulous for dieters. Most of us serious dieters long ago shifted to what are known as doctor scales. These monstrosities are accurate down to a quarter of a pound and are excellent because they tend to give very fast reinforcement to even the first day's dieting ... when it is needed the most.

The Heath scale is small ... about a foot square, if you'll pardon the expression ... and 7" high for the readout. It's light enough so you can even take it with you on trips and make your life miserable after every fantastic meal.

Like all other Heath stuff, this comes in kit form. Figure on one good evening to put it together. It's relatively simple, and no one but me could stretch one evening's work out over a couple months ... 99.9% of which was pure neglect. Now that it's done, I don't know how I got along without it.

Like many of you, I am an incipient fat person. I have all the bad traits of a fat person ... like eating because the food is there, with little relationship to any signs of hunger. I love things with butter or rich sauces, and can easily list over 500 deserts which are tops with me. Only by doing my best to keep my breakfasts and lunches simple am I able to avoid zooming up to over 250 pounds ... a weight which I have managed to attain in the past.

It's very difficult to seriously diet when I'm eating out. After all, I'm paying for the damned food, so why not eat it? So I cram down as much as I can of everything, making sure that I do my best to get my money's worth. And if I can't get it down the old hatch, it goes into a doggy bag for tomorrow night. I don't have a dog.

All this got a little out of belt a couple of years ago, so both Sherry and I started cutting down. These days, we generally order one meal between us and still end up with something to take home ... particularly if there is a salad bar. But this still calls for a careful watching of the scales at home ... and the Heath is absolutely wonderful for that. The tenth-pound readout makes it immediately apparent when I've snacked too much.

One of the better snack cutters I've found of late has been the VTR video recorder. With this system, as I've mentioned before, virtually all TV programs I watch are recorded so that I can see them without the commercials. Otherwise, I find myself getting up, wandering around, looking for something to eat during the breaks ... heck, a cup of coffee and some cookies wouldn't hurt much ... perhaps a tenth of a pound. Maybe some nuts and fruit? Better to get up and fastforward the VTR and not snack. Then there is more to see of interest on the Heath scale in the morning.

The Heath scale would make a great present for the XYL for her birthday, Mother's Day, etc. And it would be something you put together for her. It costs $99.95, which is a very good buy compared to the much less accurate doctor's scales.

DECEMBER WINNER

Johnny C. Chestnut WA4PIN and John L. Wolcott W4CCX will each be receiving a $50 bonus prize for authoring December's most popular article, "The Lunch Counter." Remember, your ballot is your Reader Service card.

Ham Help

I would like to hear from anyone who has converted a 23-channel CB Cobra Camm 88 for use on the 10 meter band, for either the Novice Tech CW portion or for the phone portion of the band.

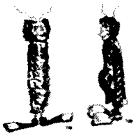
Microcomputer Interfacing

from page 24

terrupt to the microcomputer. Some real-time clocks are free-running, always keeping time. Others are programmable or preset for a particular period. The free-running clock interrupts the computer at repetitive intervals, while the programmable clock interrupts the computer only once, at the end of its preprogrammed period. Integrated circuits such as the Intel 8253 and Texas Instruments TMS 5501 contain time-keeping circuitry which is easily interfaced to most 8080 systems.

For simplicity, we will use the software clock in our example rather than an interrupt-based real-time clock. The software for the 100-point data acquisition program is shown in Table 2. After completing the program, the computer might be programmed to jump to the type of data display software discussed previously. If you look at the program carefully, you will not find a separate register used to count the 100 passes through the data acquisition software. Since the memory address stored in registers H and L is already a counter, we have chosen to detect the 200th address rather than the 100th loop. This saves an internal register. Instead of decrementing a counter and detecting the zero condition, the contents of register L are compared to the final address and equality is used to signal the end of the loop.

Analog-to-digital converters are not "instantaneous" devices which take only a few microseconds to perform a conversion. In many real situations, the analog input to the converter will vary while the ADC is trying to perform a conversion. This presents the converter with a problem. How does it know what the real value of the voltage is? In most systems, the ADC module has a *sample-and-hold* (SH) on the analog input. The SH circuitry samples the analog voltage when pulsed to provide a steady analog output to the ADC for conversion; the ADC is then pulsed to start the conversion. The Intersil IH 5110 is a typical sample-and-hold device.



OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

Corrections

A reader, Wilbur Stevens, was nice enough to point out an error in "Build a $10 Digital Thermometer" (January, 1979). In Fig. 4, on page 54, the values on the pots are reversed.

Gary McClellan
La Habra CA

Thank you for printing my OM's story about CW music ("This Station Plays Beautiful CW") in the February issue of *73*. His secretary and I both appreciate the celebration dinner made possible by the author's fee.

Nevertheless, I would like to caution the XYLs of your readers who may build a keyboard. While the diode matrix is so simple that the OM can make the hookup "while the XYL is talking," it does not necessarily follow that the OM will hear what the XYL is saying. Further, if the impasse reaches the point where not even an "uh huh" is expressed, the XYL should step up and point out that there is an error in Fig. 1. Each bus (K_0-K_7) is fed through a 10k resistor which is not shorted out as the schematic indicates.

It is a worthwhile project because, after it is completed, the XYL can carry on a CW conversation with other XYLs. All that is necessary is to use the OMs as interfaces between headsets and conventional typewriters. This will suffice until WB9WRE completes his low-cost CW typewriter.
